

There is limited data on women who have been inadvertently vaccinated with shingles vaccine during pregnancy. Therefore, as a precautionary measure, health professionals should undertake a risk assessment, including assessment of immune status similar to that for a natural exposure. Further information on the management of these women is available at [Chickenpox and shingles vaccines: advice for pregnant women](#).

Women who have inadvertently received the chickenpox vaccine can be reassured that no conditions consistent with congenital varicella syndrome have been reported. However, PHE continues to monitor reports of women who have inadvertently received the chickenpox vaccine up to 3 months before pregnancy or at any time during pregnancy and whose pregnancy outcomes are known. Women who have been immunised with chickenpox vaccine in pregnancy should be reported to [PHE Vaccine in Pregnancy Surveillance](#).

Pregnant women who are inadvertently vaccinated with either chickenpox or shingles vaccine should be advised to seek prompt medical advice if they develop a vesicular rash post vaccination.
