For additional information including regional data on COVID-19 and other respiratory viruses, COVID-19 in educational settings, co- and secondary infections with COVID-19 and other data supplementary to this report, please refer to the [accompanying graph pack](#).

Corrections

This report was corrected on 18 January 2023 after editorial errors were found in the text totals of the Respiratory DataMart section for count of SARS-COV-2 tests conducted, positive SARS-CoV-2 test results, and overall count of positive influenza tests (second and third paragraphs on page 14). These have been corrected. Percentage positivity and influenza subtype counts in text and figures were correct and are unchanged.

Executive summary

This report summarises the information from the surveillance systems which are used to monitor coronavirus (COVID-19), influenza, and other seasonal respiratory viruses in England. References to COVID-19 represent the disease name and SARS-CoV-2 represent the virus name. The report is based on data from week 1 (between 2 January and 8 January 2023) and for some indicators daily data up to 10 January 2023.

Overall

In week 1, from activity seen across multiple disease surveillance systems, influenza activity decreased compared to week 52. COVID-19 activity has also decreased in most indicators.

COVID-19

COVID-19 case rates through Pillar 1 slightly decreased. Case rates decreased in most regions and most age groups.

Through Respiratory Datamart, SARS-CoV-2 positivity decreased to 7.7% compared with 8.9% the previous week.

Through primary care surveillance, COVID-19 indicators remained broadly stable compared with week 52.

The overall number of reported COVID-19 confirmed outbreaks increased compared with the previous week. The highest number of incidents continue to be in care homes, with 133 COVID-19 confirmed outbreaks occurring in England in week 1 compared with 53 in week 52.

Overall, COVID-19 hospitalisations and ICU admissions decreased in week 1 compared with week 52. Hospitalisations were highest in the 85 years and over age group. Through syndromic surveillance indicators, emergency department attendances for covid-like illness decreased nationally.

Deaths with COVID-19 increased in week 52.

The COVID-19 Autumn booster vaccination campaign commenced in early September. By the end of week 1, 64.3% of all people aged over 50 years had been vaccinated with an Autumn booster dose.

Influenza

In week 1, influenza positivity decreased to 12.2% compared with 25.2% in week 52; with highest positivity seen in the 5 to 14 years age group at 17.0%.

Through primary care surveillance, the influenza-like-illness consultations indicator remained stable in week 1, in the medium activity level.

The overall number of reported influenza-confirmed outbreaks decreased in week 1 compared with week 52. The highest number of incidents continue to be in care homes, with 49 influenza confirmed outbreaks occurring in England in week 1 compared with 88 in week 52.

Influenza hospital admissions decreased in week 1 compared with the previous week. The week 51 and 52 admissions rates were revised up retrospectively with the receipt of new data. The rate decreased in week 1 to the medium activity range. Admissions data is provisional. Influenza admissions were highest in the 85 years and over and 75 to 84 years age groups. Influenza ICU admissions decreased in week 1, remaining within the medium intensity range.

Emergency department attendances for influenza-like illness decreased nationally, for all age groups and regions.

Influenza vaccine uptake for the 2022 to 2023 influenza season has been reported weekly since week 41. The trend in vaccine uptake compared with the previous 2021 to 2022 season is broadly comparable for those 65 years and over and for those under 65 years in clinical risk groups, although the difference between this season and last has increased throughout December in these groups. Influenza vaccine uptake in pregnant women and 2 and 3 year olds is lower than last season.

RSV

The overall positivity for RSV continued to decrease to 5.1% with the highest positivity of 13.2% in under 5 year olds. Decreases in positivity were seen in most age groups. The RSV hospitalisation rate decreased overall, including in the under 5 years age group. Emergency department attendances for acute bronchiolitis decreased nationally.

Other viruses

Adenovirus positivity remained low and stable at 2.4%. Rhinovirus positivity decreased to 7.2% overall. Parainfluenza positivity remained low and stable at 1.1%. Human metapneumovirus (hMPV) positivity decreased to 4.8%, with the highest positivity seen in children under 5 years of age.

Other indicators

Through NHS 111, calls for cold and flu and for cough decreased nationally compared with week 52, and in all age groups.

The primary care lower respiratory tract infection rate increased compared with week 52.

Emergency department attendances for acute respiratory infection decreased nationally, and in all age groups.

Excess deaths (from all cause) were observed in week 52.

Laboratory surveillance

Confirmed COVID-19 cases (England)

From 1 April 2022, the government ended provision of widespread community testing in England, as outlined in the plan for [living with COVID-19](#). From week 15 2022, confirmed COVID-19 episodes and positivity through Pillar 1 are presented in this report, with Pillar 2 data available in the accompanying graph pack. Routine asymptomatic testing through NHS settings has been paused from 31 August, this will have an effect on Pillar 1 case rates and positivity rates.

As of 9am on 8 January 2023, a total of 1,973,605 episodes have been confirmed for COVID-19 in England under Pillar 1, and 20,483,922 episodes have been confirmed under Pillar 2, since the beginning of the pandemic. COVID-19 case rates through Pillar 1 decreased in week 1 compared with week 52. Case rates decreased in most regions and most age groups in week 1 compared with week 52.

Data notes:

Changes to testing policies over time may affect positivity rates and incidence rates and should be interpreted accordingly. From 31 January 2022, UK Health Security Agency (UKHSA) moved all COVID-19 case reporting in England to use a new episode-based definition which includes possible reinfections. Each infection episode is counted separately if there are at least 91 days between positive test results (polymerase chain reaction (PCR) or rapid lateral flow device). Each infection episode begins with the earliest positive specimen date. Further information can be found on the [UK COVID-19 dashboard](#).

From the week 32 2021 report onwards, case rates have been updated to use the latest Office for National Statistics (ONS) population estimates for mid-2020. Previously case rates were calculated using the mid-2019 population estimates. Rates by ethnicity and Indices of Multiple Deprivation (IMD) quantile will continue to be presented using the mid-2019 estimates, until the mid-2020 estimates become available.

Please note that positivity is presented as positivity by PCR testing only. Positivity is calculated as the number of individuals testing positive during the week divided by the number of individuals tested during the week through PCR testing.

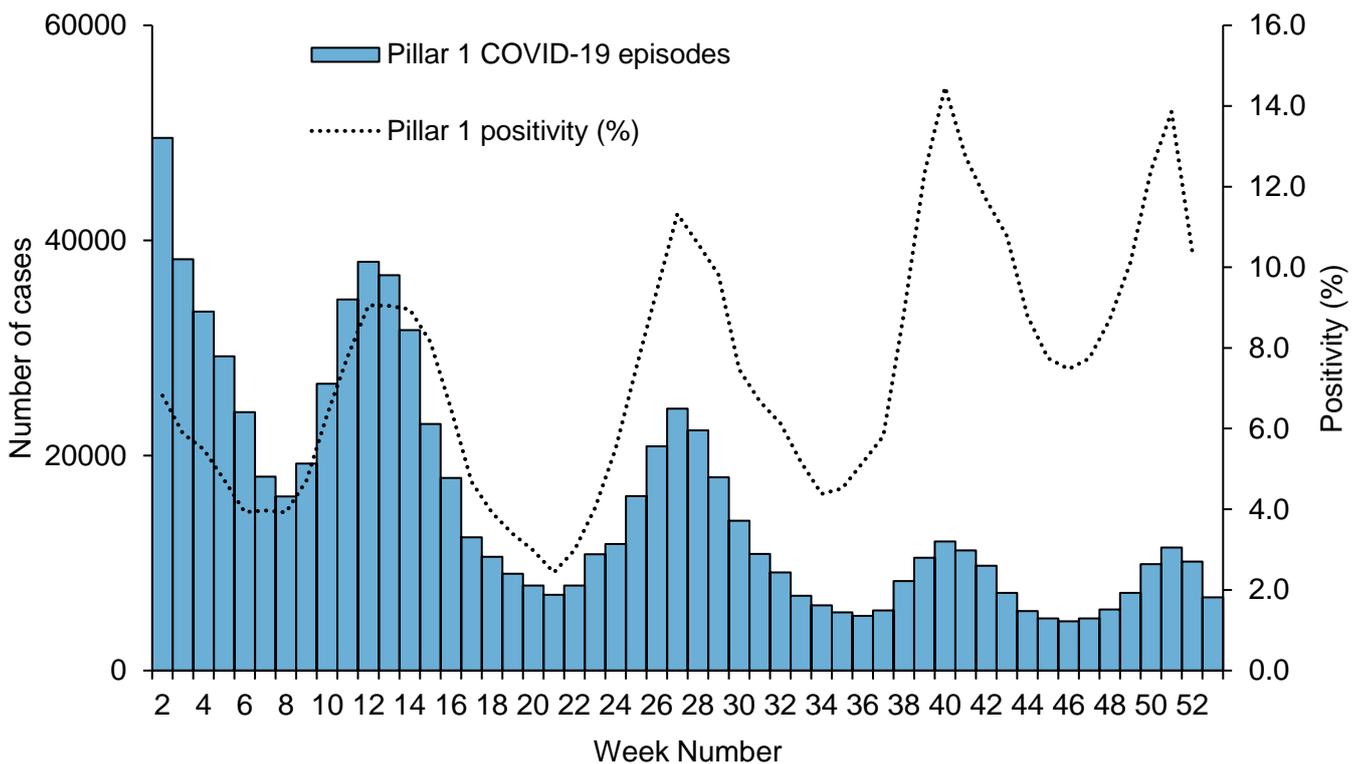

Data is shown by the week the specimen was taken from the person being tested. This gives the most accurate analysis of this time progression. However, for the most recent week results for more samples are expected therefore this should be interpreted with caution.

Data from the most recent week is subject to reporting lags and may change in future iterations.

Pillar 1 positivity metrics for the most recent week have been omitted due to a possible data processing issue which is being investigated. Please refer to the DataMart data on SARS-CoV2 positivity in figure 11.

Data source: Second Generation Surveillance System (SGSS)

Ethnicity

Figure 9: Weekly incidence per 100,000 population by ethnicity (Pillar 1), England

*The incidence rates on Figure 9 have been calculated using the mid-2019 ONS population estimates. Due to a data issue, the figures for the mixed ethnicity group have been removed from week 43 onwards, pending its resolution.

Possible SARS-CoV-2 reinfection in England

SARS-CoV-2 reinfections data is not currently being published. For previous updates please see previous editions of this report.

Respiratory DataMart system (England)

The Respiratory Datamart system began during the 2009 influenza pandemic to collate all laboratory testing information in England. It is now used as a sentinel laboratory surveillance tool, monitoring all major respiratory viruses in England. Sixteen laboratories in England will be reporting data for this season. As this is based on a sample of labs, SARS-CoV-2 positivity figures quoted here will differ from those quoted in the Confirmed COVID-19 cases section, however, they are included to allow comparison with data on other respiratory viruses.

In week 1 of 2023, out of the 15,755 respiratory specimens reported through the Respiratory DataMart System (based on data received from 16 out of 16 laboratories), 1,211 samples were positive for SARS-CoV-2 with an overall positivity of 7.7% which decreased from 8.9% the previous week. The highest positivity was seen in those 65 years and over at 10.8%.

Influenza positivity decreased from 25.2% in week 52 to 12.2% in week 1, with highest positivity seen in the 5 to 14 years age group at 17.0%. 999 samples tested positive for influenza (274 flu A(H3), 27 flu A(H1N1)pdm09, 618 flu A(not subtyped) and 80 flu B) in week 1 (Figure 12).

The overall positivity for RSV continued to decrease to 5.1% with the highest positivity of 13.2% in the under 5 years age group.

Adenovirus positivity remained low at 2.4%, with the highest positivity in the under 5 years age group at 9.0%.

Rhinovirus positivity decreased to 7.2% overall, with the highest positivity in the under 5 years age group at 10.9%.

Parainfluenza positivity remained stable at 1.1%.

Human metapneumovirus (hMPV) positivity decreased slightly to 4.8% from 5.4% the previous week.

Community surveillance

Acute respiratory infection incidents

Here we present data on acute respiratory infection (ARI) incidents in different settings that are reported to UKHSA Health Protection Teams (HPTs) and entered onto an online web-based platform called HPZone. Incidents are suspected outbreaks of acute respiratory infections linked to a particular setting. All suspected outbreaks are further investigated by the HPT in liaison with local partners.

The ARI definition includes presentations of both an influenza-like illness (ILI) and other acute viral respiratory infections (AVRI). Causal pathogens can include Influenza A and B, Respiratory Syncytial Virus (RSV), adenovirus, rhinovirus, parainfluenza, human metapneumovirus (hMPV) and SARS-CoV-2.

Data for England, Scotland and Northern Ireland are included in the UK figures.

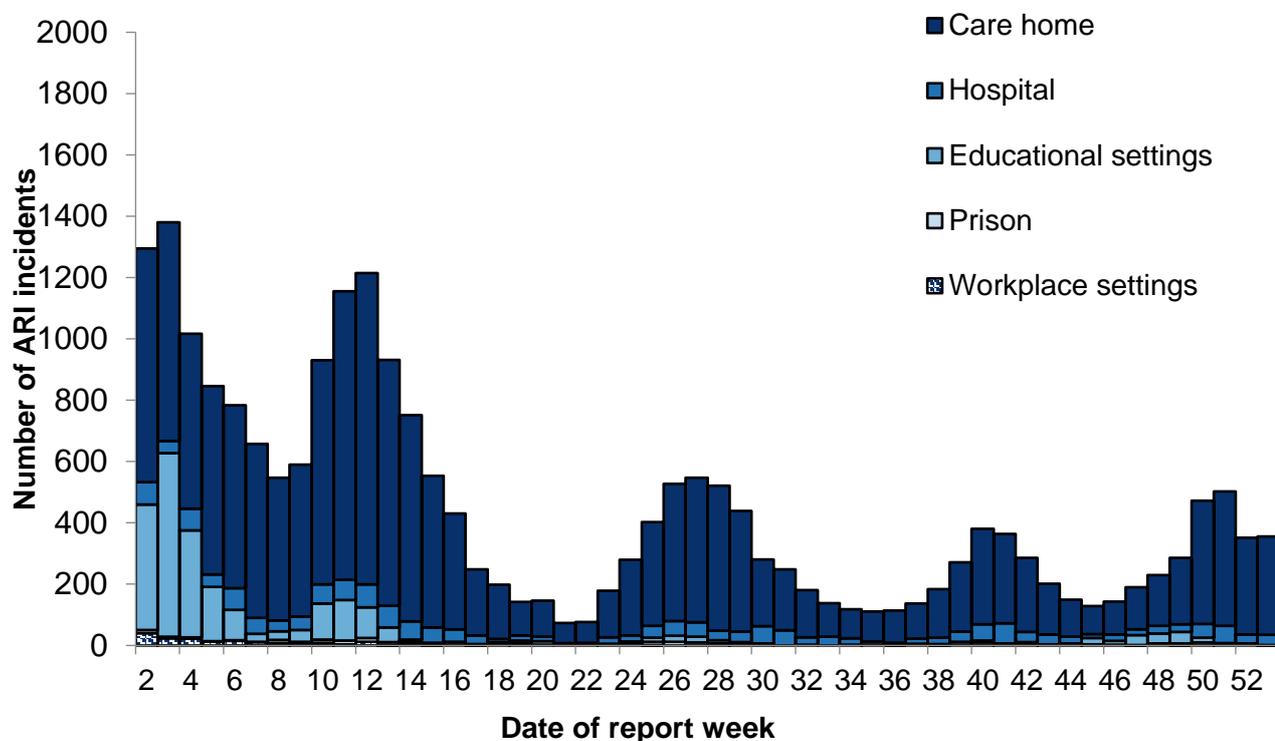

Data caveats:

1. The incidents captured on HPZone represent a subset of all ongoing ARI clusters and outbreaks in England rather than an exhaustive listing.
2. In addition, SARS-CoV2 testing policies and public health guidance for different settings changed over time. This means that any interpretation of seasonal and temporal trends since March 2020 should take this into account.
3. It should be noted that the denominator for the different settings will vary significantly. For example, there are fewer hospitals than workplaces. In addition, the propensity to report incidents to UKHSA also varies significantly by setting. This needs to be considered when interpreting the weekly number of reported incidents by setting and caution should be used when making comparisons between settings.
4. Considering the above, comparisons between regions and settings are not advised as they may be misleading.

406 new ARI incidents have been reported in week 1 in the UK (Figure 18):

- 321 incidents were from care homes where 151 had at least one linked case that tested positive for SARS-CoV-2, 49 for influenza A (not subtyped), 1 for influenza B, 1 for influenza (not typed), 2 for RSV and 1 for hMPV
- 34 incidents were from hospitals, where 23 had at least one linked case that tested positive for SARS-CoV-2 and 2 for influenza A (not subtyped)
- 1 incident was from a prison, with no test results available
- 50 incidents were from other settings where 11 had at least one linked case that tested positive for SARS-CoV-2, 12 for influenza A (not subtyped), 2 for RSV and 1 for influenza (not typed)

FluSurvey

An internet-based surveillance system has been developed based on FluSurvey. FluSurvey is a web tool survey designed to monitor trends of influenza-like illness (ILI) in the community using self-reported respiratory symptoms from registered participants. The platform has been adapted to capture respiratory symptoms, exposure risk and healthcare seeking behaviours among registered participants to contribute to national surveillance of COVID-19 activity as well as influenza activity since week 44 2020.

Note that ILI is defined as sudden onset of symptoms with at least one of fever (chills), malaise, headache, muscle pain and at least one of cough, sore throat, shortness of breath.

During week 1, there were 2,278 participants completing the weekly symptoms questionnaire of which 387 (17.0%) reported fever or cough and 87 (3.8%) reported influenza like illness (ILI). There was a decrease in both COVID-19 related symptoms and influenza like illness (ILI) amongst participants completing the weekly symptoms survey from rates reported in week 52. Healthcare seeking behaviour amongst participants reporting respiratory symptoms relating to COVID-19 (cough, fever, or loss of smell) showed that participants were more likely to telephone their GP provider as a result of their symptoms when compared to other healthcare services (Figure 25).

Self-reported daily social contact patterns are also reported. A contact is defined as a person outside the household who is approached at a distance of less than one metre, on the day prior to survey completion. There remains variation on social mixing patterns amongst participants as people are meeting more individuals outside of their households (Figure 26).

Figure 25: FluSurvey participants self-reporting fever or cough and ILI symptoms, and trends in healthcare seeking behaviour among these participants, England

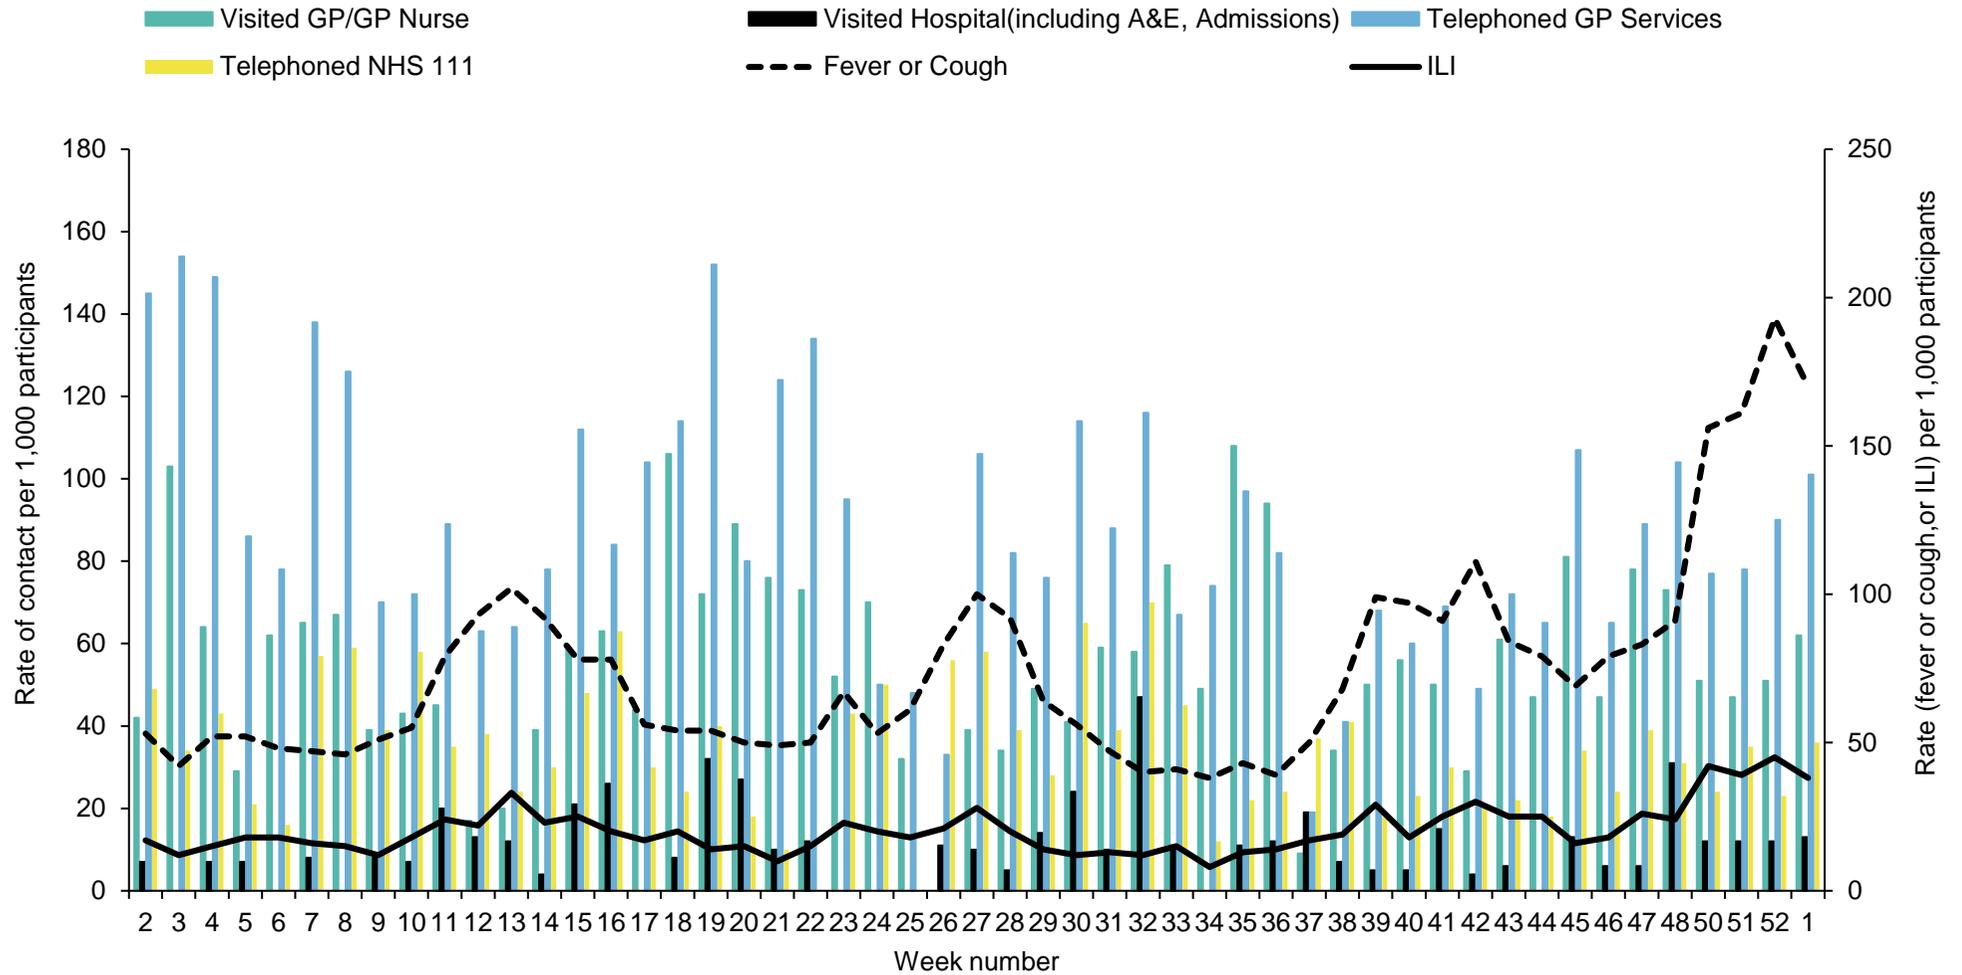

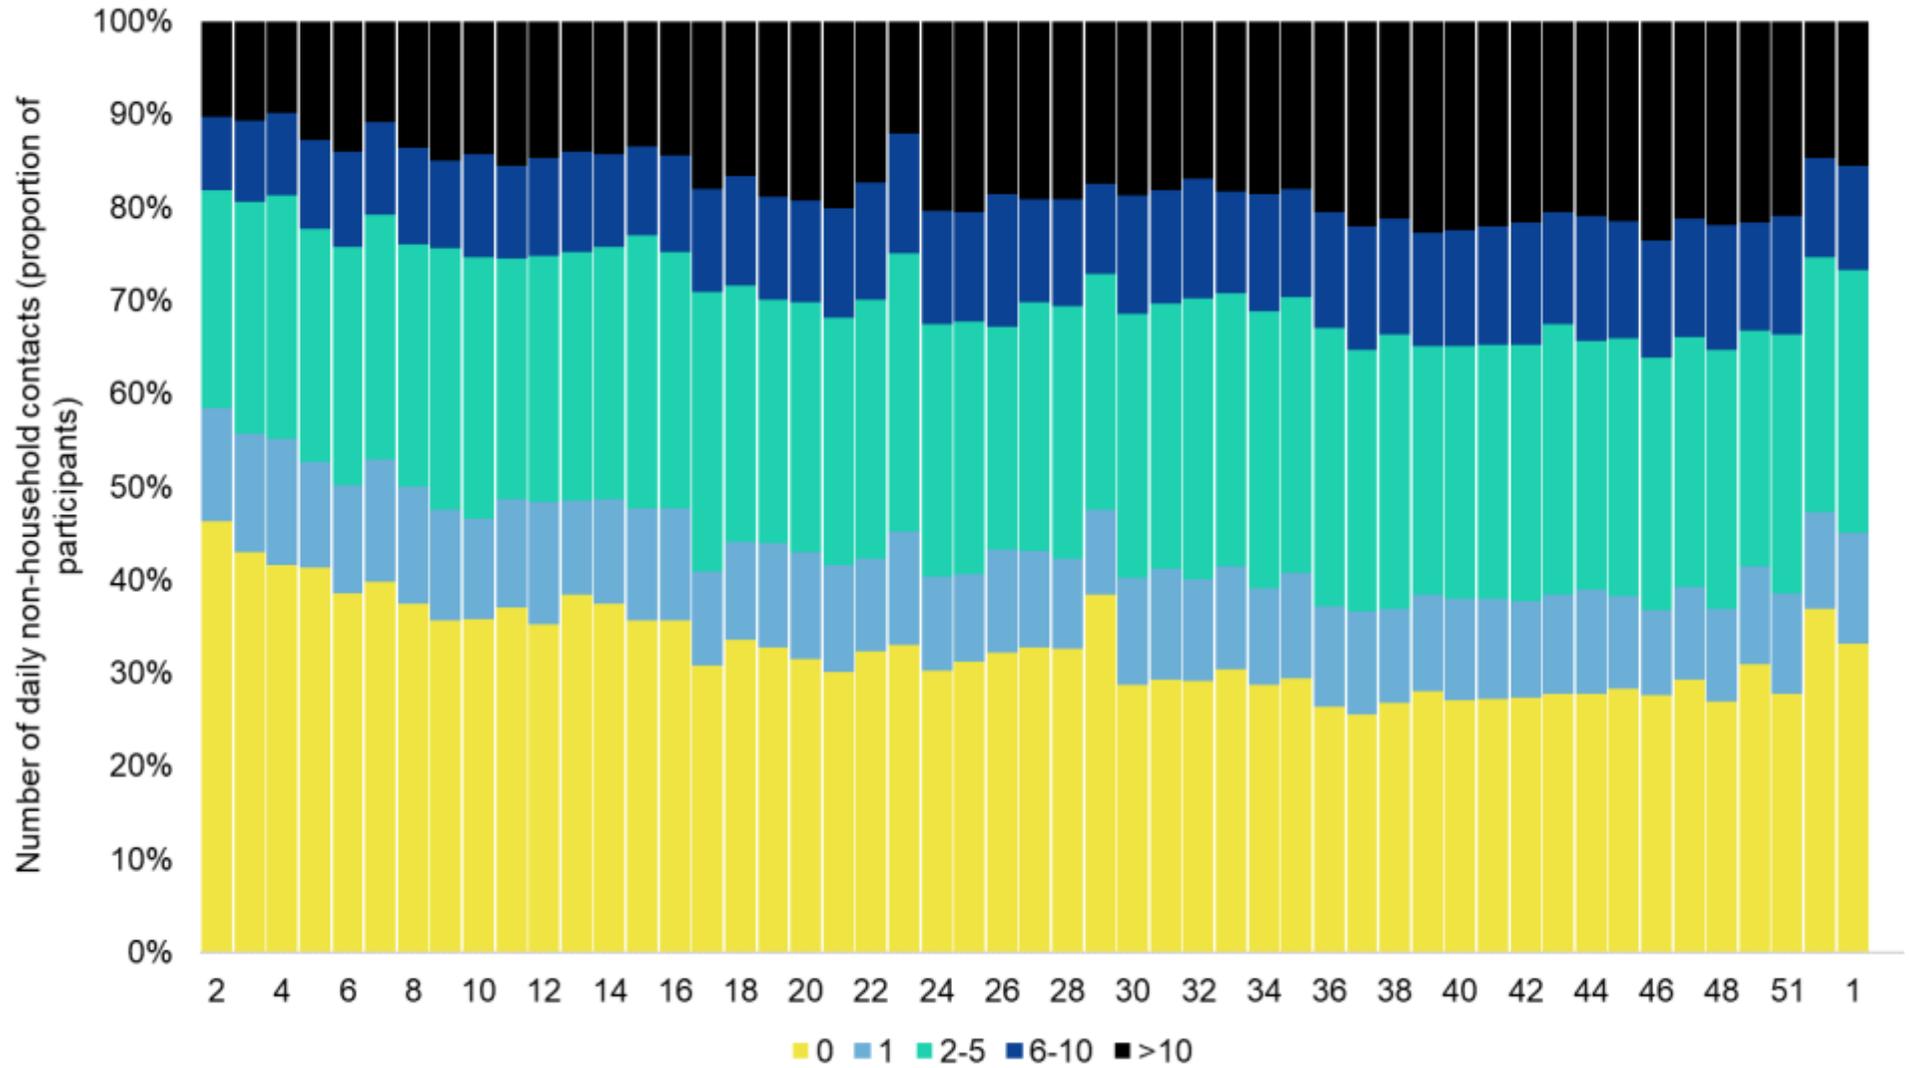

Figure 26: FluSurvey participants' self-reported number of social contacts outside the household

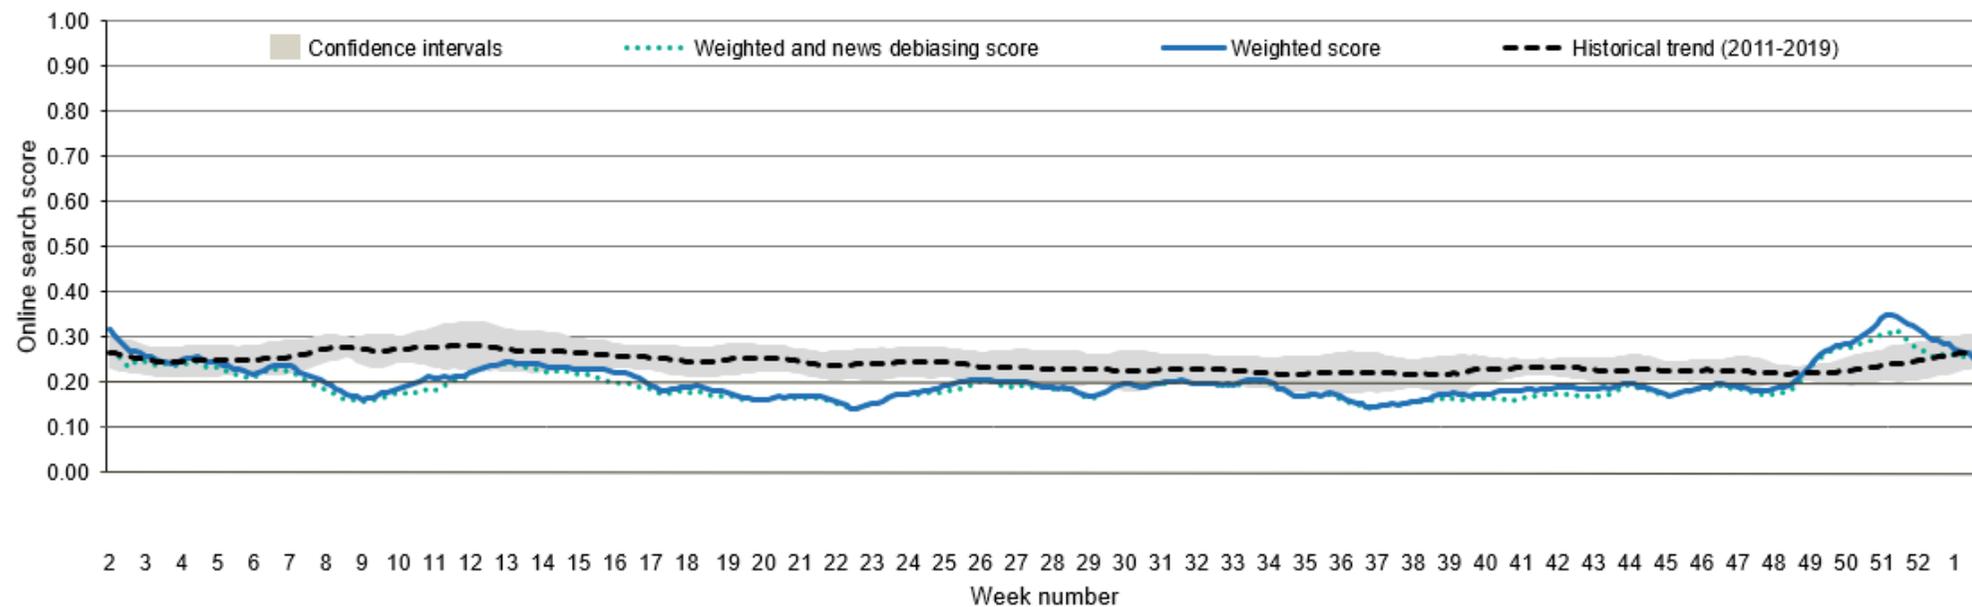

Google search queries

This is a web-based syndromic surveillance system which uses daily search query frequency statistics obtained from the Google Health Trends API (Application Programming Interface). This model focuses on search queries about COVID-19 symptoms as well as generic queries about 'coronavirus' (for example 'COVID-19'). The search query frequency time series is weighted based on symptom frequency as reported in other data sources. Frequency of searches for symptoms is compared with a baseline calculated from historical daily data. [Further information on this model](#) is available online.

During week 1, the overall and media-debiasing weighted Google search scores decreased slightly compared to week 52 (Figure 27).

Figure 27: Normalised Google search score for COVID-19 symptoms, with weighted score for media-debiasing and historical trend, England

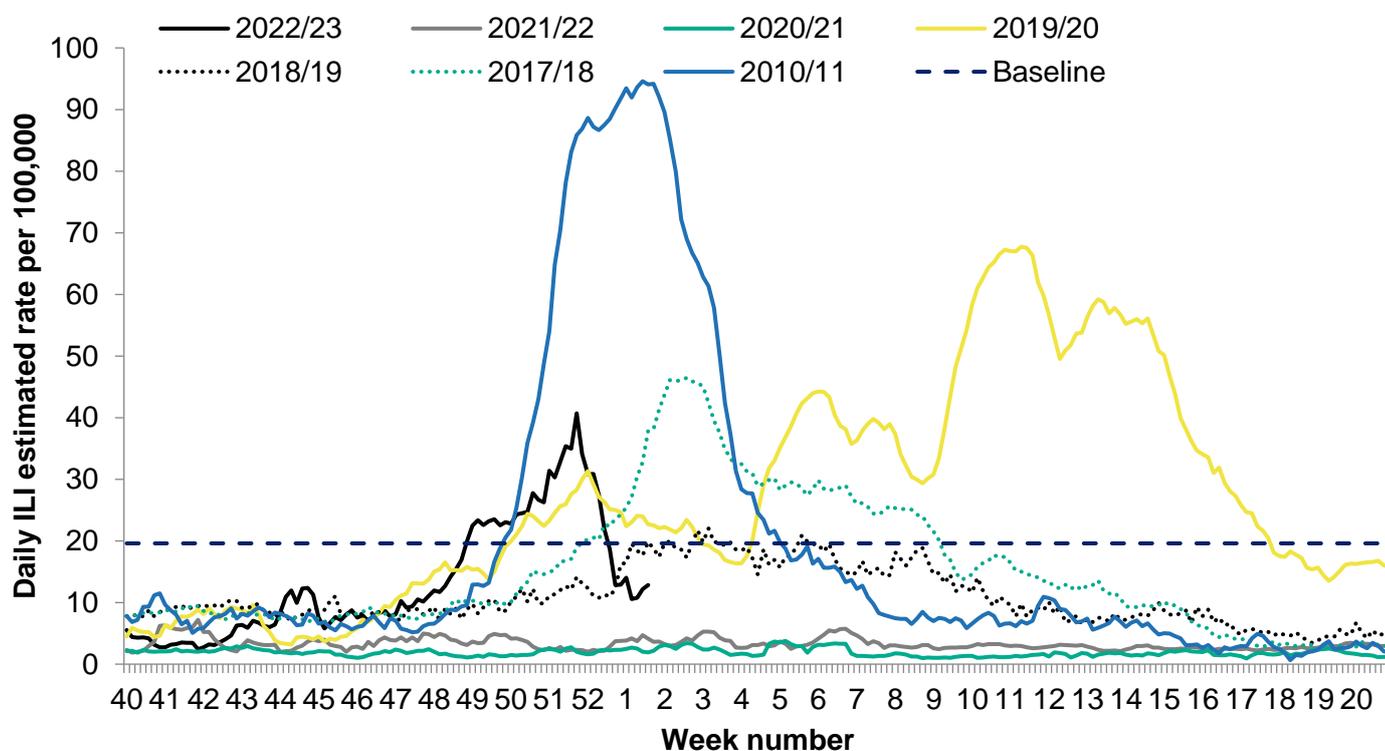

Flu Detector

FluDetector is a web-based model which assesses internet-based search queries for ILI in the general population.

Daily ILI rate estimates are based on uniformly averaged search query frequencies for a week-long period (including the current day and the 6 days before it).

For week 1, the daily ILI rate decreased compared to week 52 and remained below the baseline threshold of 19.6 per 100,000 for the 2022 to 2023 season (Figure 28).

Figure 28: Daily estimated ILI Google search query rates per 100,000 population, England

NHS 111

Please note that different syndromic surveillance indicators (NHS 111, GP in hours, GP out of hours and emergency department attendances) are presented here than have been included in previous versions of this report. All indicators previously presented will continue to be published in the [Syndromic Surveillance bulletins](#).

The [NHS 111 service](#) monitors daily trends in phone calls made to the service in England, to capture trends in infectious diseases such as influenza and norovirus.

Please note that the number of NHS 111 calls are still lower than usual due to widely publicised disruption faced by a clinical software system. The NHS 111 call data presented in this report should therefore be interpreted with some caution.

During week 1, NHS 111 calls for cold or flu and cough decreased nationally, and in all age groups. (Figure 29 and 30).

Please note that NHS 111 callers (from 11 May 2020) who are assessed as having probable COVID-19 symptoms are now triaged using symptom specific pathways such as cold or flu, which are included in routine syndromic indicators.

Further information about these caveats is available from the [Remote Health Advice Syndromic Surveillance bulletin](#).

Figure 29: NHS 111 telephony indicators (and 7-day moving average) for number of daily cold or flu calls, England (a) nationally and (b) by age group

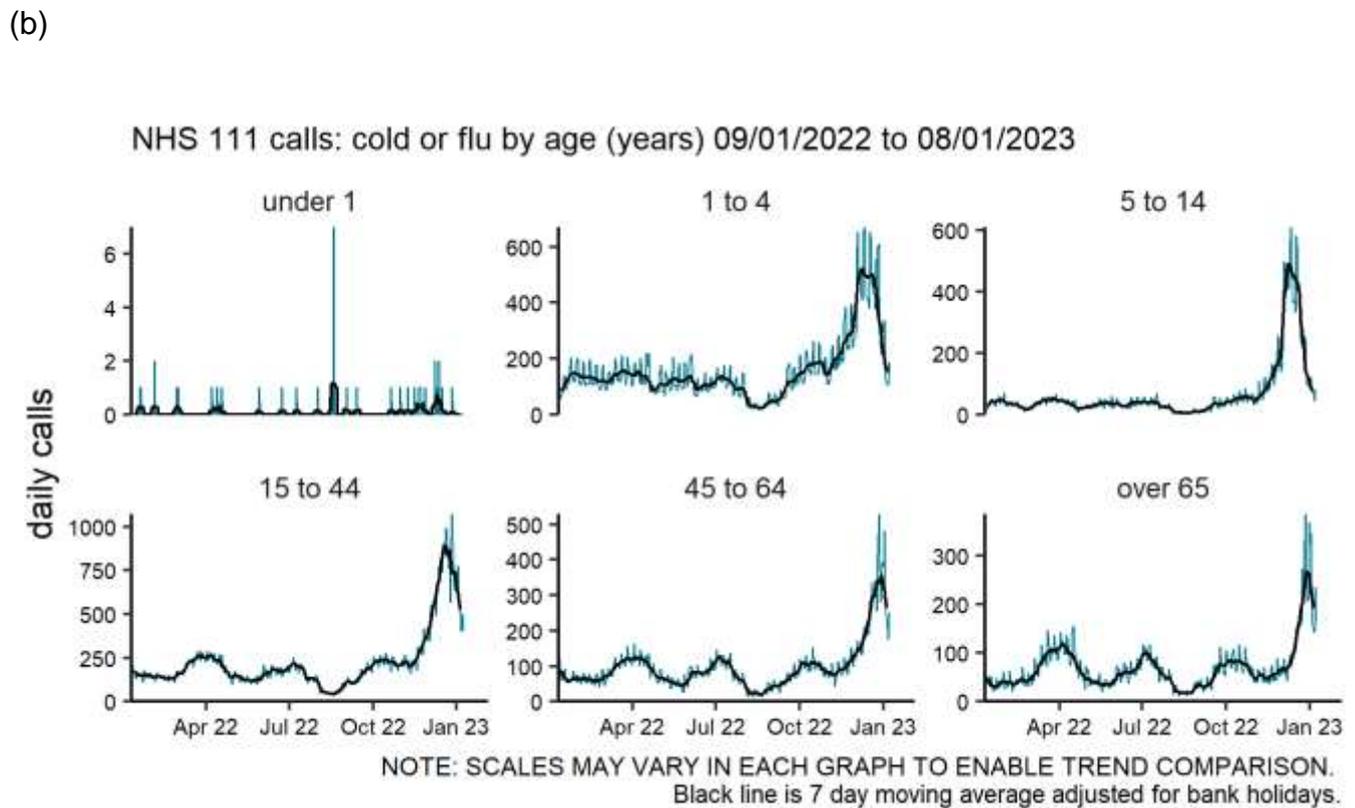

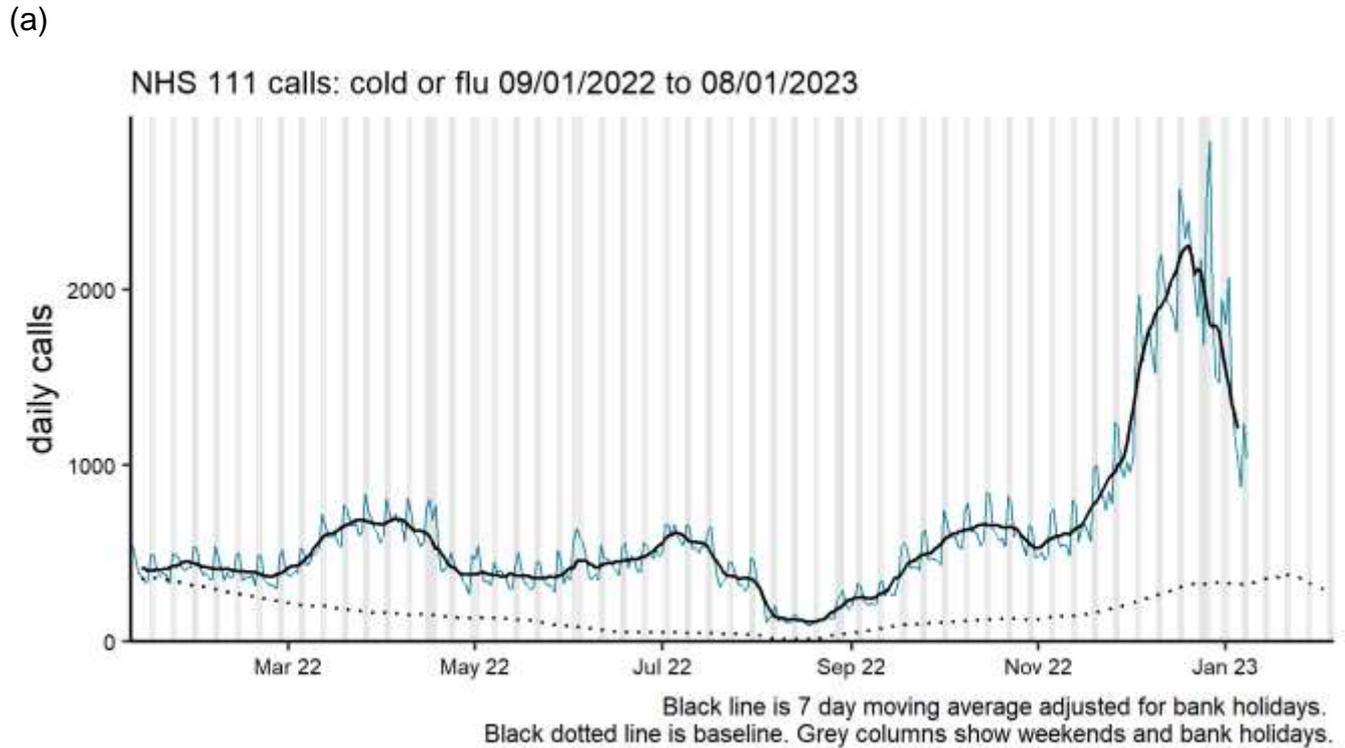

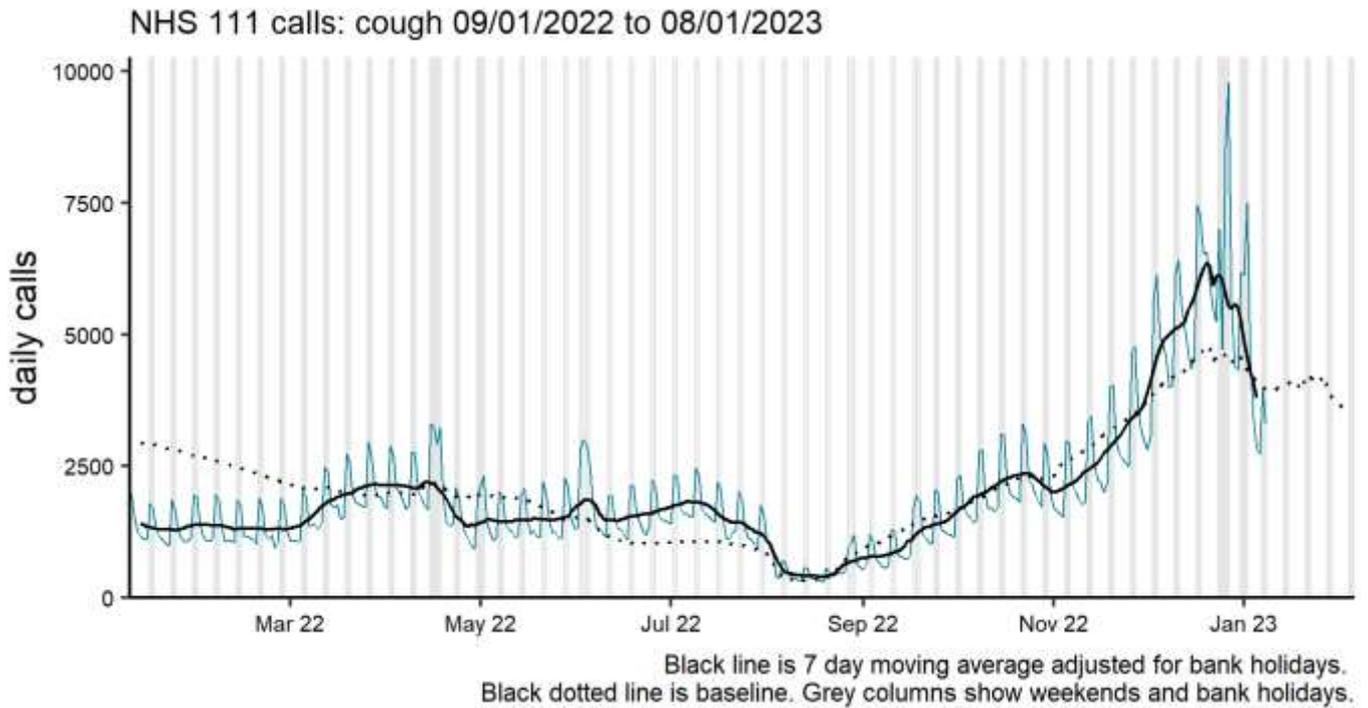

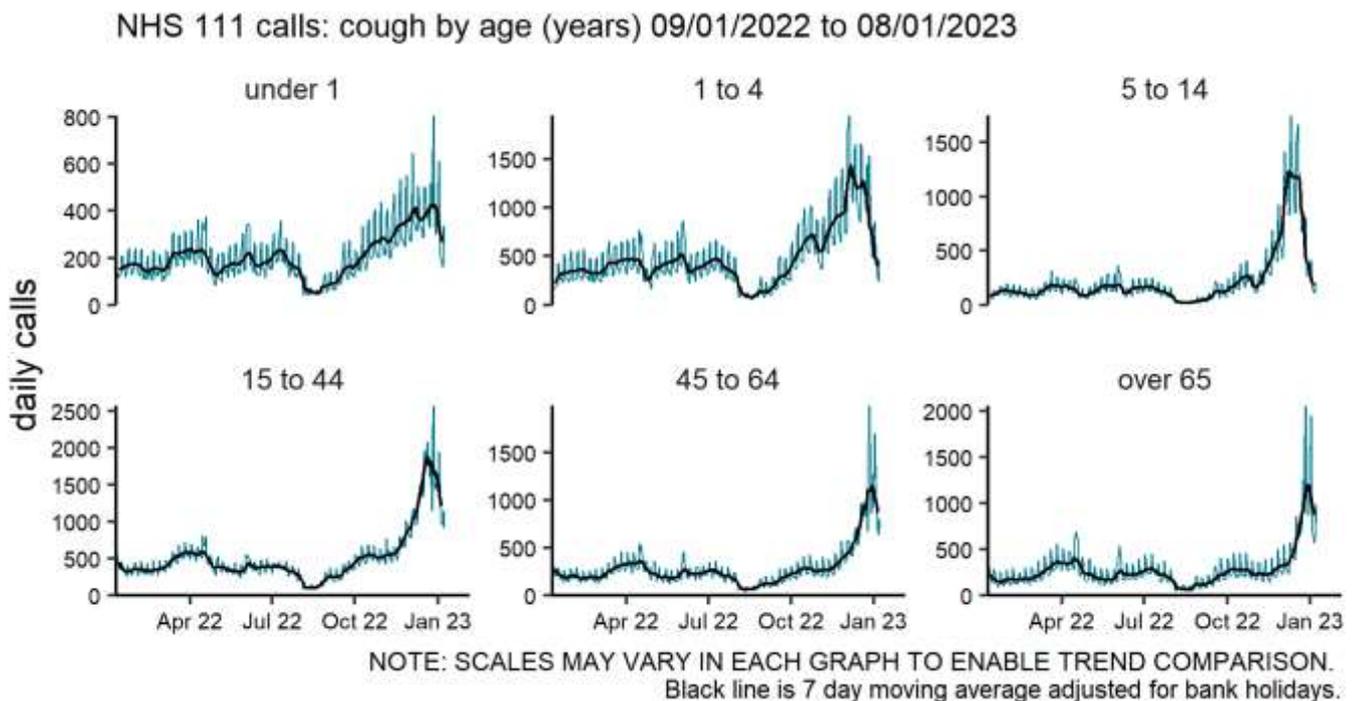

Figure 30: NHS 111 telephony indicators (and 7-day moving average) for number of daily cough calls, England (a) nationally and (b) by age group

(b)

Primary care surveillance

RCGP (England)

The weekly ILI consultation rate through the RCGP surveillance was 21.1 per 100,000 registered population in participating GP practices in week 1 compared to 20.9 per 100,000 in the previous week. This remains at medium activity level (between 15.06 and 46.46 per 100,000) (Figure 31). By age group, the highest rates were seen in the under 1 year olds (34.2 per 100,000), followed by the 75 and over years olds (34.1 per 100,000). The lower respiratory tract infections (LRTI) consultation rate was at 130.6 per 100,000 in week 1, compared to the rate of 120.5 per 100,000 in the previous week. The COVID-19 indicator rate was at 44.2 per 100,000 in week 1 compared to a rate of 40.6 per 100,000 in the previous week (Figure 32).

Figure 31: RCGP influenza-like illness (ILI) consultation rates, all ages, England

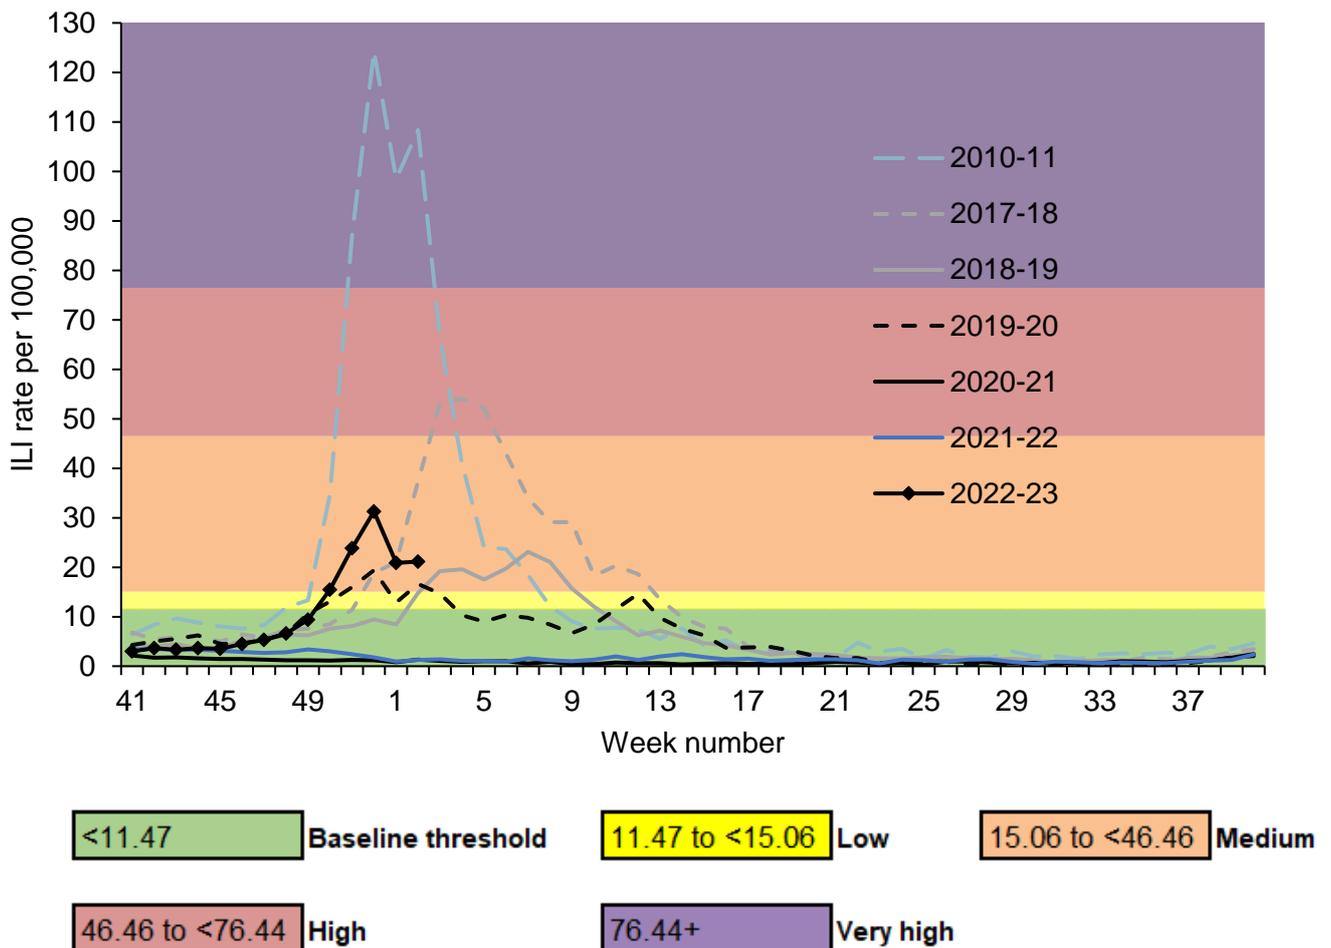

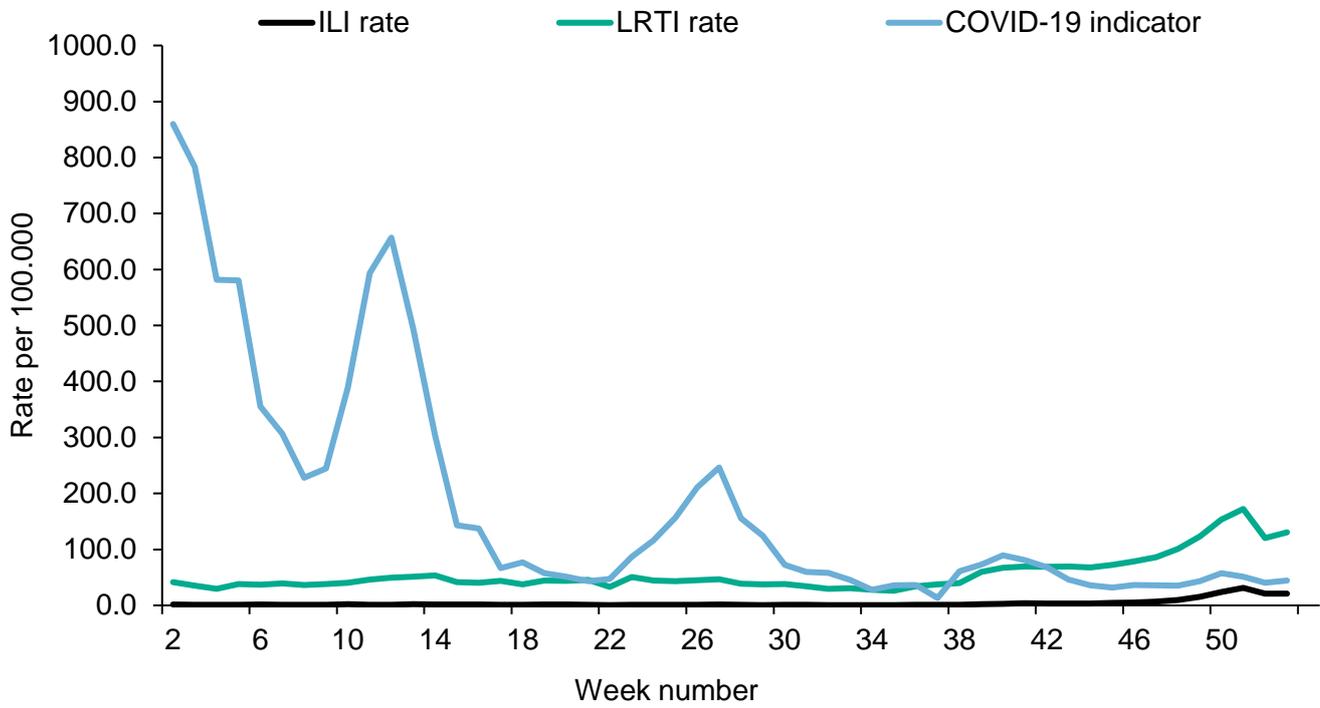

Figure 32: RCGP ILI, LRTI and COVID-19 indicator rates, England

UK

Overall, weekly ILI consultations rates increased slightly and remained at medium activity level in England. Wales and Scotland activity decreased and Northern Ireland activity increased (Table 2).

By age group, the highest incidence was in the under 1 year olds in England (34.2 per 100,000), and in the 75 year olds and over in Scotland (32.6 per 100,000), Wales (30.8 per 100,000) and Northern Ireland (23.9 per 100,000).

Table 2: GP ILI consultations in the UK for all ages with MEM (Moving Epidemic Method) thresholds applied

GP ILI consultation rates (all ages)	Week number													
	40	41	42	43	44	45	46	47	48	49	50	51	52	1
England (RCGP)	3.0	3.7	3.3	3.6	3.5	4.5	5.3	6.6	9.4	15.5	23.9	31.3	20.9	21.1
Wales	3.5	2.8	3.9	4.8	6.3	7.0	3.5	4.3	7.8	14.1	24.2	39.1	34.8	22.8
Scotland	2.1	1.8	4.0	3.8	3.5	4.8	4.6	3.0	5.9	7.2	11.3	20.2	31.9	20.3
Northern Ireland	1.3	2.2	1.8	3.5	3.0	3.7	3.5	4.9	5.0	6.0	9.4	17.8	14.0	17.7

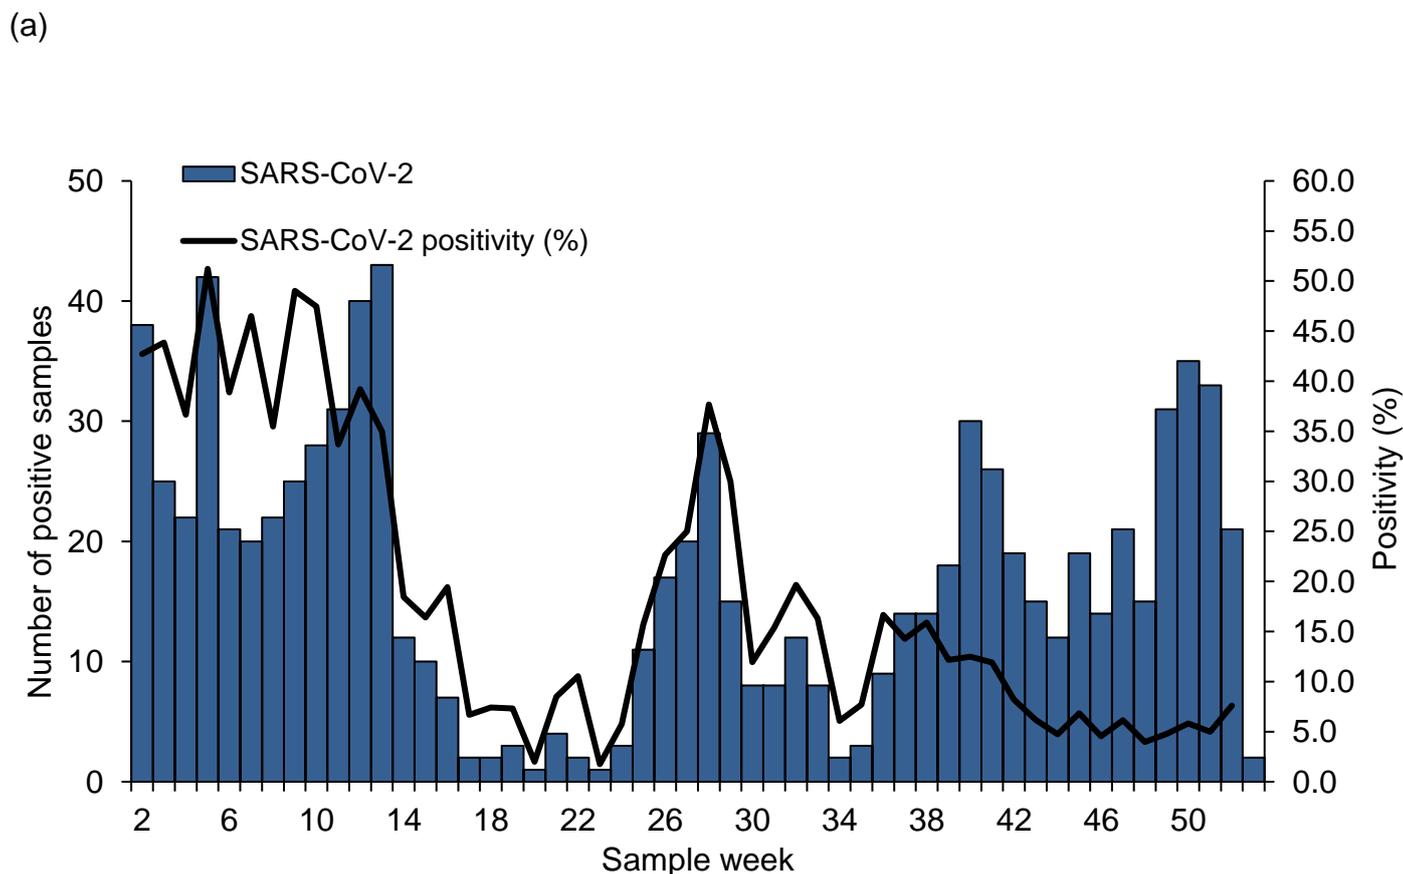

The Moving Epidemic Method (MEM) has been adopted by the European Centre for Disease Prevention and Control to calculate thresholds for GP ILI consultations for the start of influenza activity (based on 10 seasons excluding 2020 to 2021), in a standardised approach across Europe.

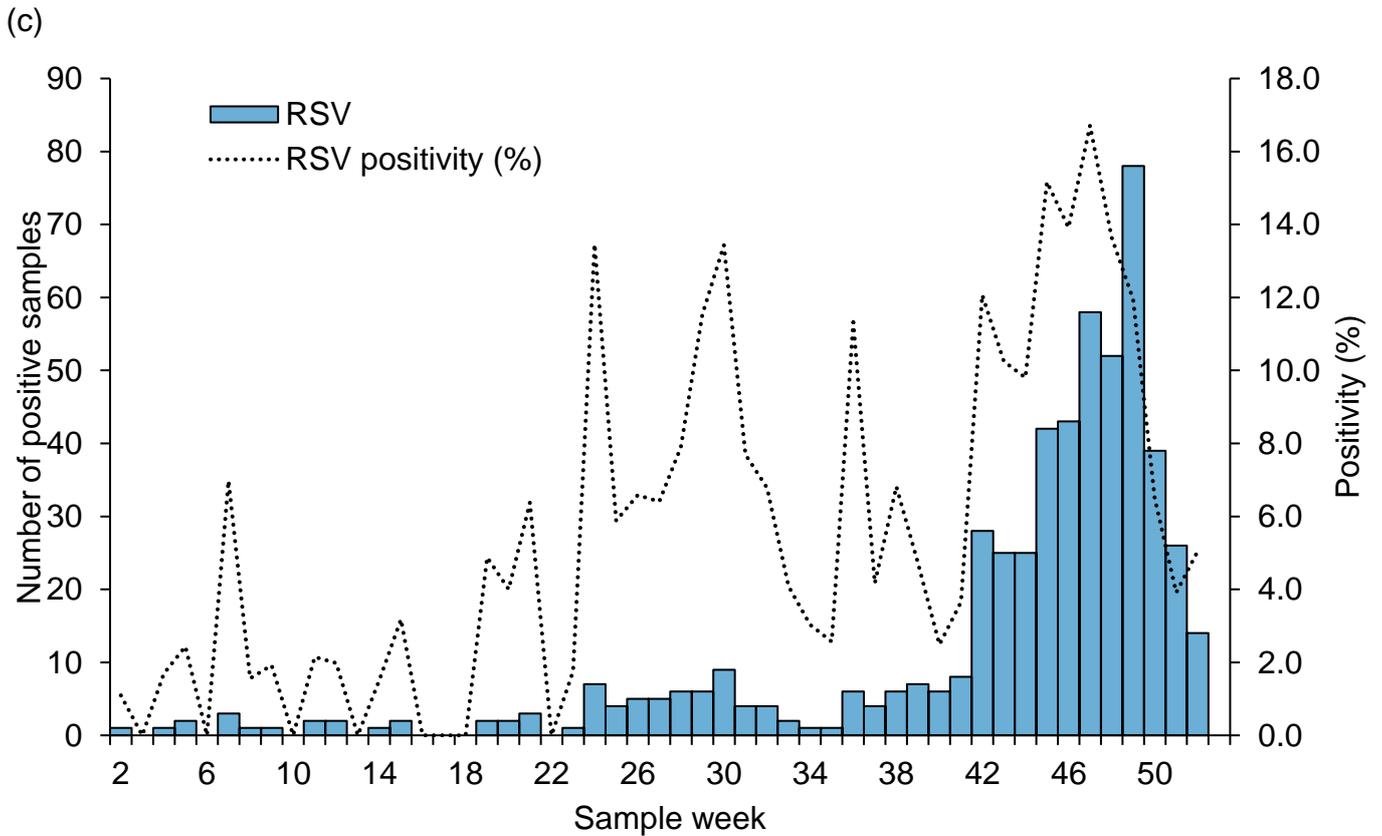

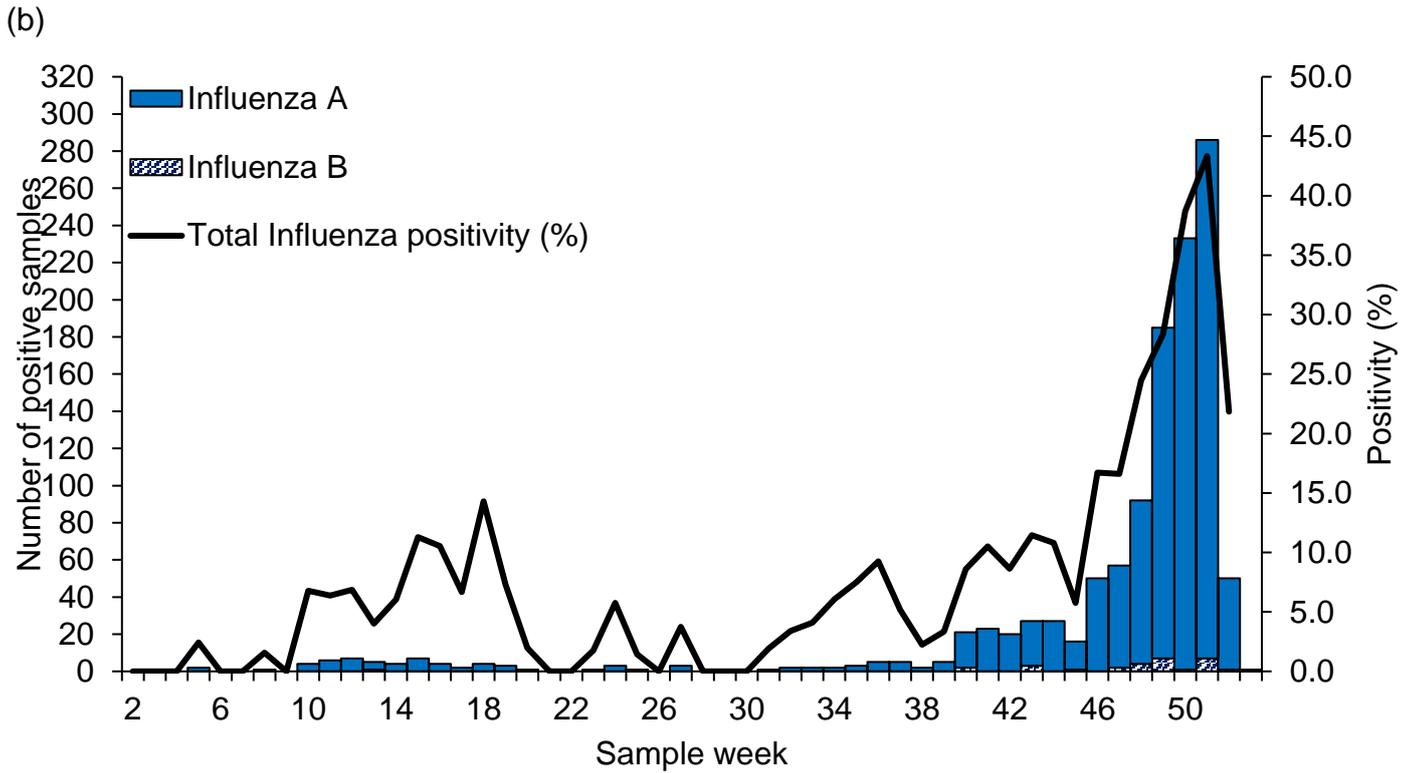

Sentinel swabbing scheme in England

In week 52 2022, 276 samples were tested for SARS-CoV-2 through the GP sentinel swabbing scheme in England, of which 21 samples tested positive. 277 samples were tested for RSV, of which 14 tested positive. 229 samples were tested for influenza, of which 50 samples tested positive. In week 1 2023, less than 20 samples were tested therefore we were unable to estimate positivity (Figure 33).

* Please note that due to lower sample numbers, data from week 14 of 2022 onwards should be interpreted with caution.

Figure 33: Number of positive samples and weekly positivity (%) for (a) COVID-19 and (b) Influenza and (c) RSV, GP sentinel swabbing scheme

*For the most recent week, more samples are expected to be tested therefore the graphs in Figure 34 should be interpreted with caution

*Positivity (%) is not calculated when the total number tested is less than 10

GP In Hours, Syndromic Surveillance

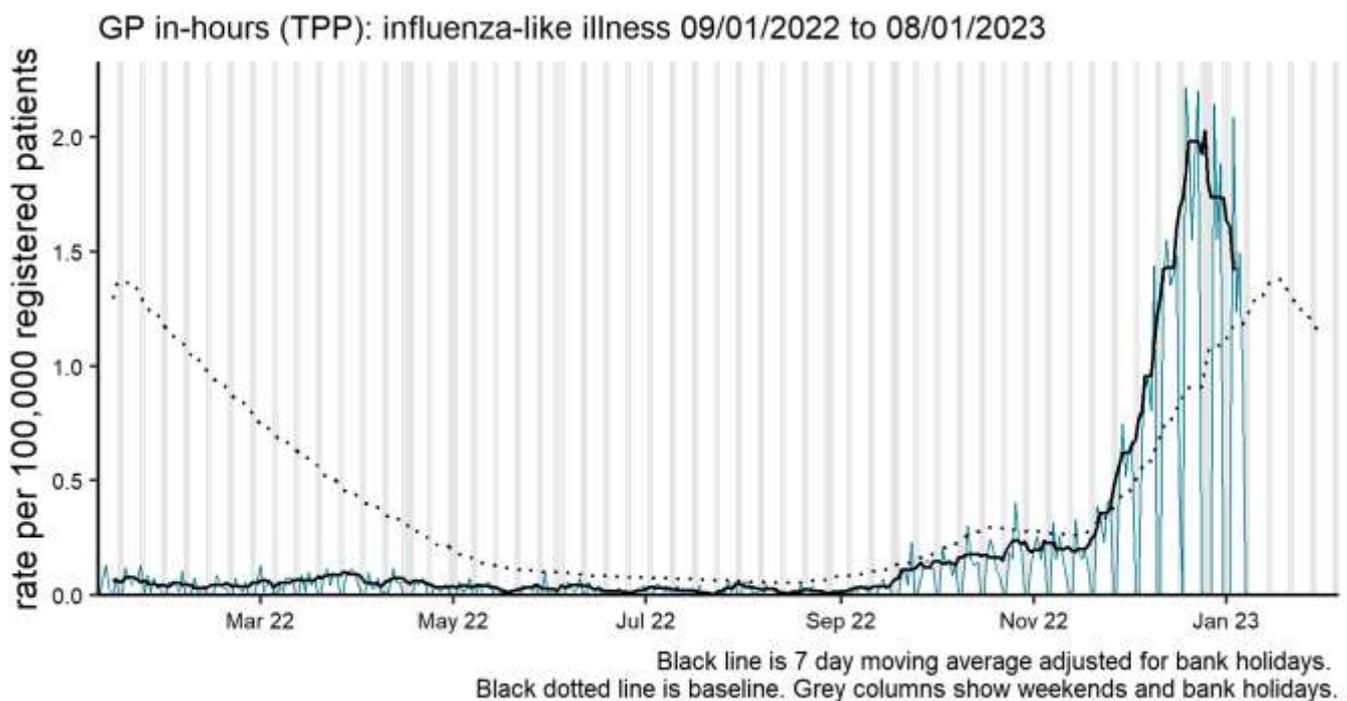

The GP In Hours (GPIH) syndromic surveillance system monitors the number of GP visits during regular hours of known clinical indicators.

During week 1, GP in-hours consultation rates for influenza-like illness decreased (Figure 34).

Further indicators and information about caveats are available from the [GP In Hours Syndromic Surveillance bulletin](#).

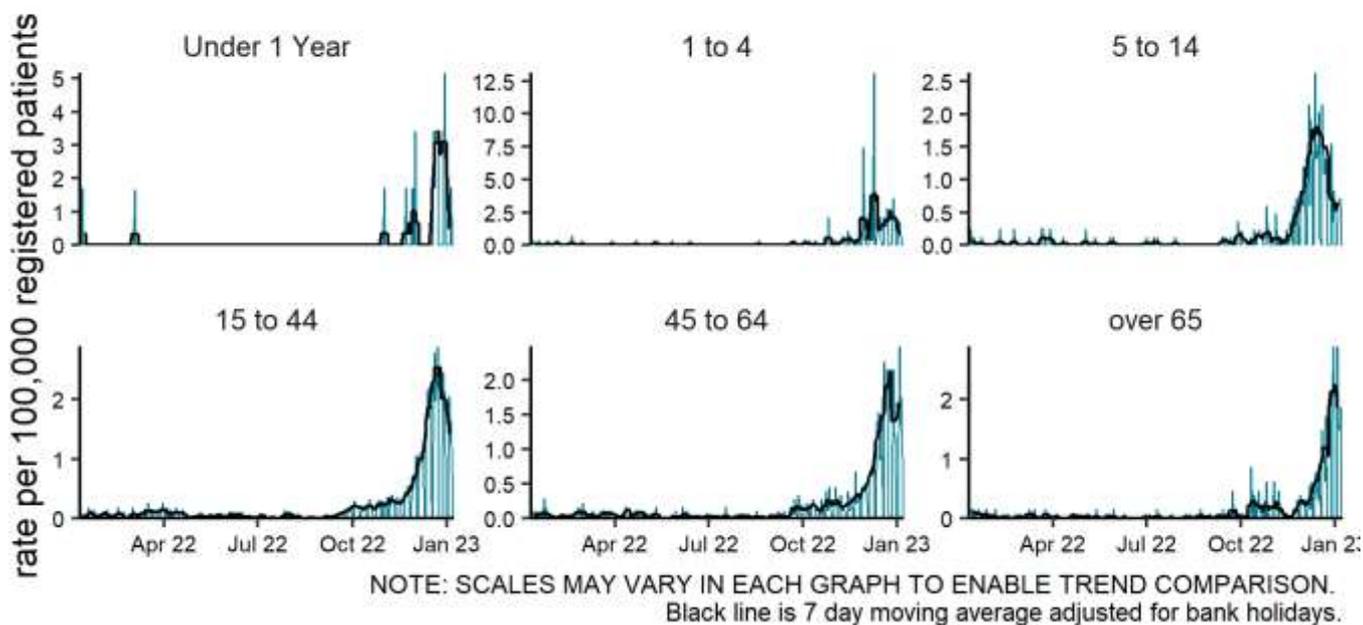

Figure 34: GPIH clinical indicators for influenza-like illness GP consultations, England (a) nationally, (b) by age group and (c) by UKHSA centre

(a)

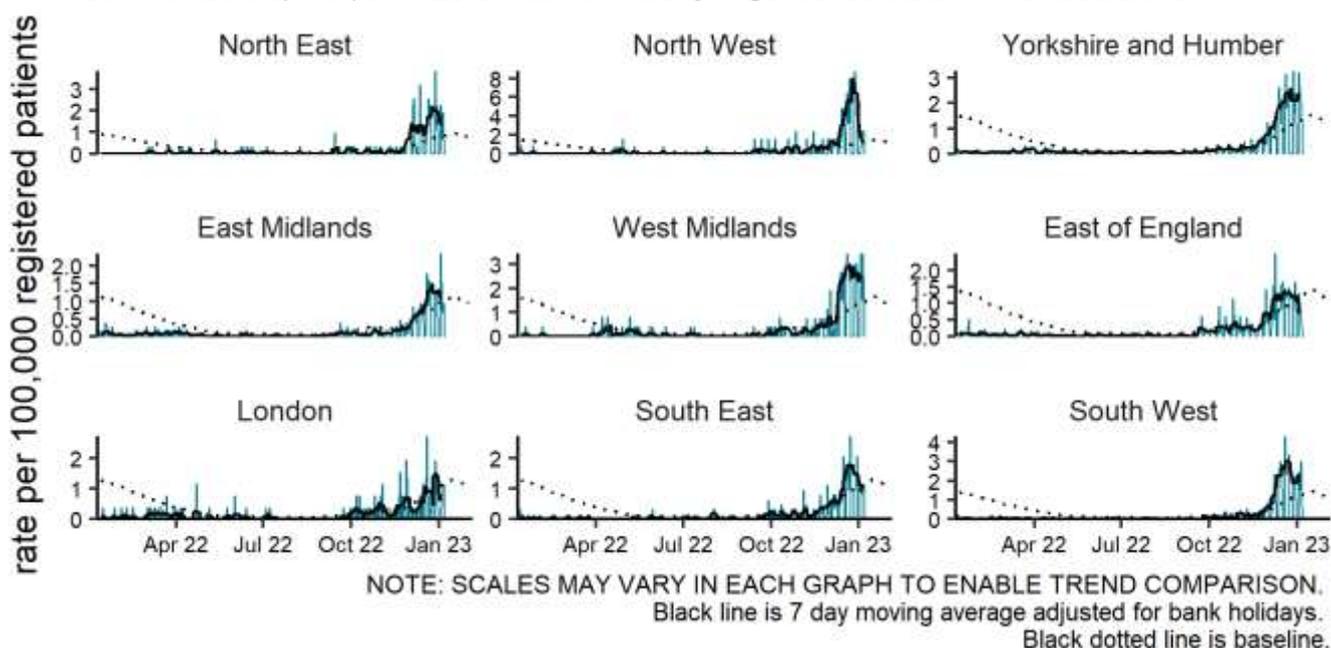

(b)

GP in-hours (TPP): influenza-like illness by age (years) 09/01/2022 to 08/01/2023

(c)

GP in-hours (TPP): influenza-like illness by region 09/01/2022 to 08/01/2023

GPIH Baselines are modelled from historical data to give current seasonally expected levels. GP consultations rates decreased during 2020 due to changes in guidance on accessing health care, therefore separate modelled estimates are provided to show seasonally expected levels pre-COVID-19.

GP Out of Hours, Syndromic Surveillance

The GP Out of Hours (GPOOH) syndromic surveillance system monitors the numbers of daily unscheduled visits and calls to GPs during evenings, overnight, on weekends and on public holidays. This system covers around 55% of England's out of hour activity.

Due to a disruption with a GPOOH clinical software system provider, GPOOH data from 4 August onwards is not currently available. Data from GPOOH systems will be added back into this report once available. The most recent data is available in [previous reports](#).

Secondary care surveillance

SARI Watch

The Severe Acute Respiratory Infection (SARI) Watch surveillance system was established in 2020 to report the number of laboratory-confirmed influenza and COVID-19 cases admitted to hospital and critical care units (ICU and HDU) in NHS acute trusts across England. This has replaced the UK Severe Influenza Surveillance Schemes (USISS) Mandatory and Sentinel data collections for influenza surveillance used in previous seasons, and the COVID-19 hospitalisations in England surveillance system (CHESS) collections for COVID-19 surveillance.

The weekly rate of new admissions of COVID-19, influenza and RSV cases is based on the trust catchment population of those NHS Trusts who made a new return. This may differ from other published figures such as the total number of people currently in hospital with COVID-19.

The Moving Epidemic Method (MEM) thresholds for influenza hospital and ICU or HDU admissions are calculated based on the 2016 to 2017 to the 2021 to 2022 seasons (data from 2020 to 2021 was excluded due to the COVID-19 pandemic). These thresholds have been applied to data from the 2022 to 2023 season onwards.

Trends in hospital and critical care admission rates need to be interpreted in the context of testing recommendations. Please note that routine asymptomatic testing for SARS-CoV-2 through NHS settings has been paused from 31 August 2022, therefore SARI-Watch data should be interpreted with this in mind.

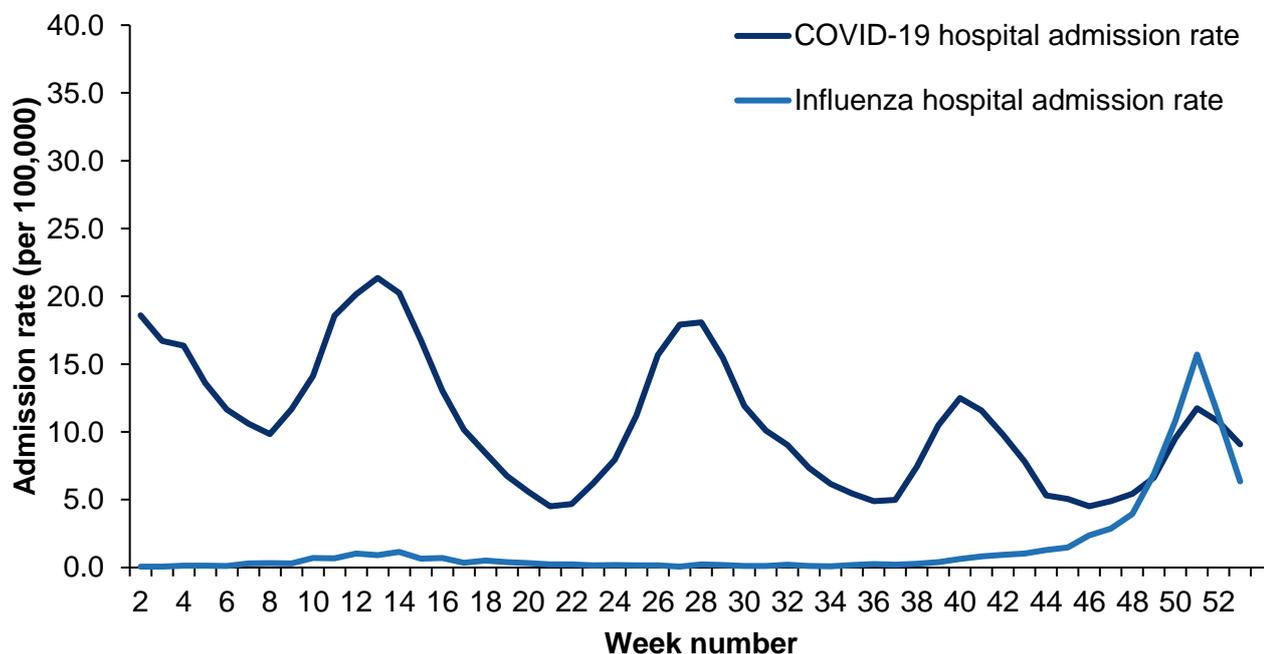

Hospitalisations, SARI Watch

In week 1 (ending 8 January 2023), the overall weekly hospital admission rate for COVID-19 decreased to 9.08 per 100,000 compared to 10.76 per 100,000 in the previous week.

By UKHSA centre, the highest hospital admission rate for COVID-19 was observed in the North East. By age group, the highest hospital admission rate for confirmed COVID-19 continues to be in the 85 year olds and over (with a decrease across all age groups in week 1).

In week 1 (ending 8 January 2023), the overall weekly hospital admission rate for influenza decreased to 6.35 per 100,000 compared to 11.17 per 100,000 in the previous week. The rate in week 51 2022 was updated to 15.71/100,000 due to retrospective data submissions. The rate in the latest week has fallen to the medium impact range. By UKHSA Centre, the highest hospitalisation rate was observed in the North East. By age group, the highest hospital admission rate for influenza was in the 85 year olds and over. There were 561 new hospital admissions to sentinel Trusts for influenza (34 influenza A(H1N1)pdm09, 43 influenza A(H3N2), 443 influenza A(not subtyped) and 41 influenza B) in week 1.

Figure 35: Weekly overall hospital admission rates of new COVID-19 and influenza positive cases per 100,000 population reported through SARI Watch, England

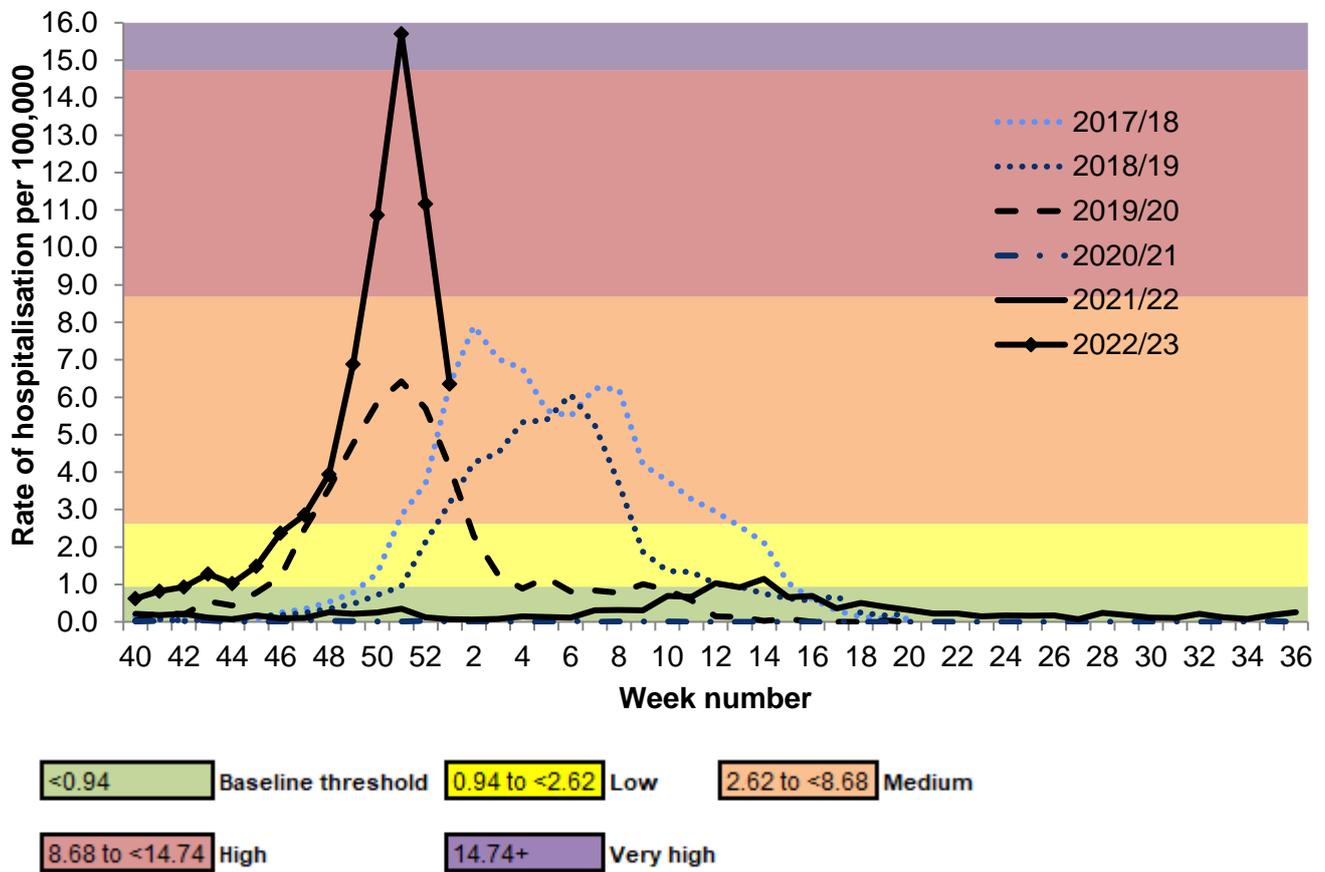

* Influenza hospital admission rate based on 21 sentinel NHS trusts for week 1

* COVID-19 hospital admission rate based on 91 NHS trusts for week 1

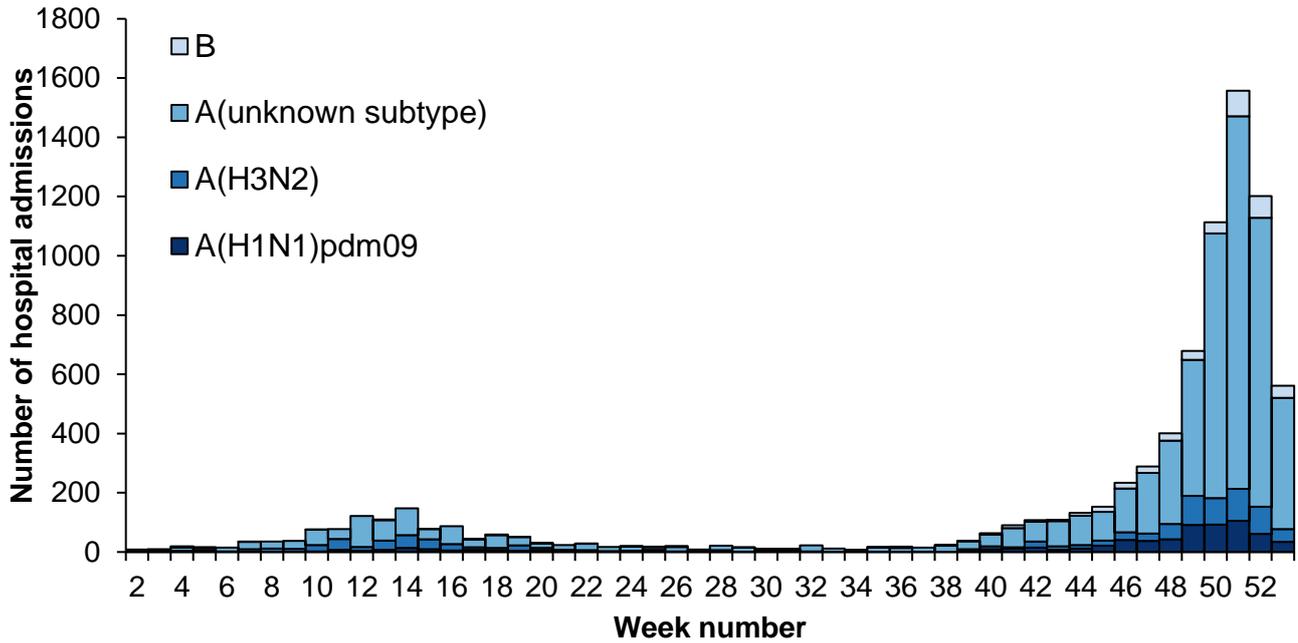

* SARI Watch data is provisional

Figure 36: Weekly overall influenza hospital admission rates per 100,000 trust catchment population with MEM thresholds, SARI Watch, England

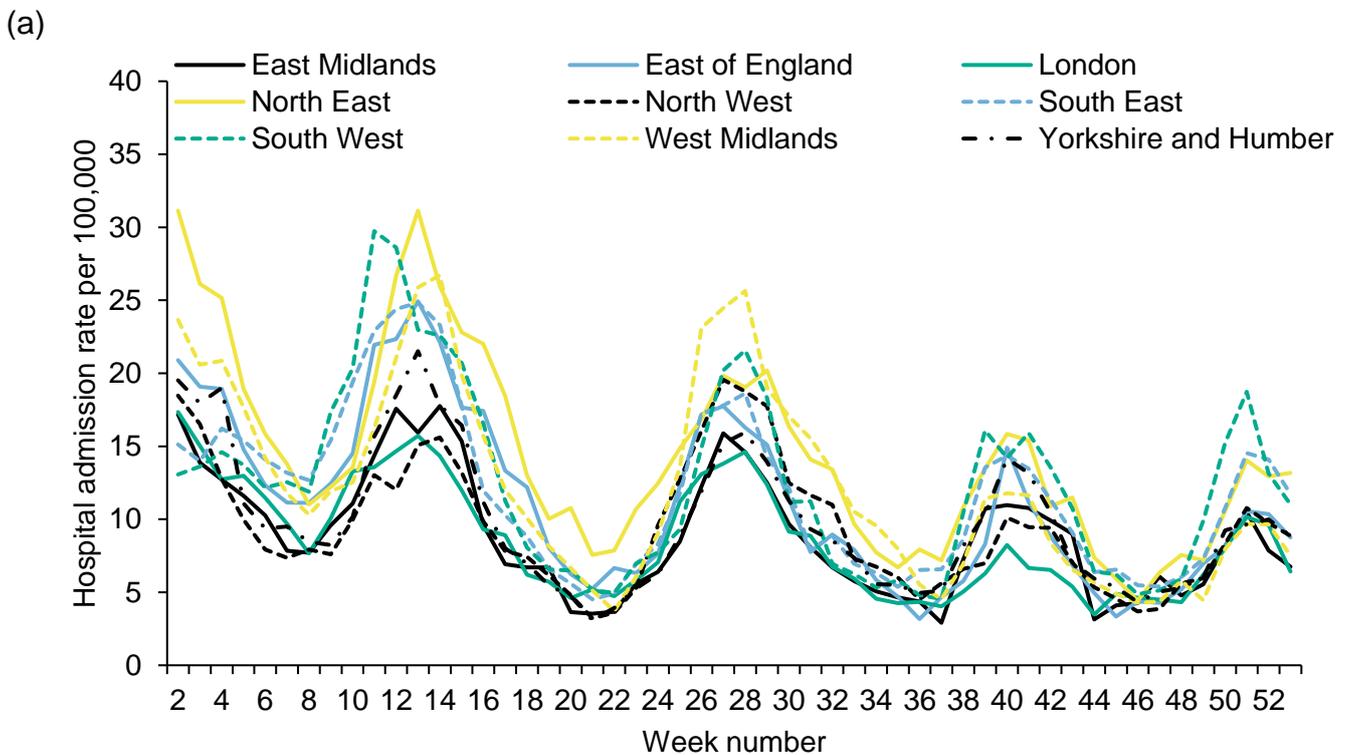

* MEM thresholds are based on data from the 2016 to 2017 to the 2021 to 2022 seasons (data from 2020 to 2021 was excluded due to the COVID-19 pandemic).

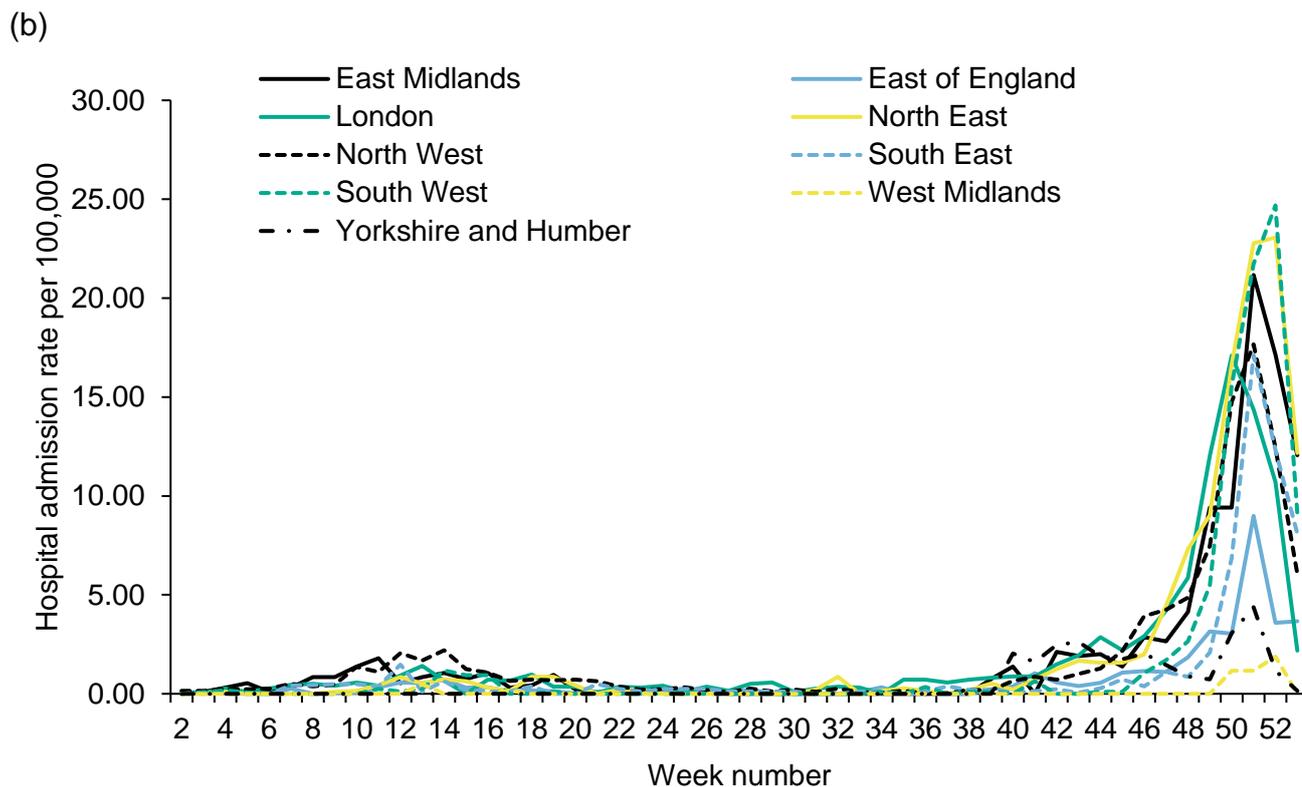

Figure 37: Weekly influenza hospital admissions by influenza type, SARI Watch, England

* Rates in some regions may not include all influenza surveillance sentinel sites from week to week

Figure 39: Weekly hospital admission rate by age group for new (a) COVID-19 positive cases and (b) influenza reported through SARI Watch

(b)

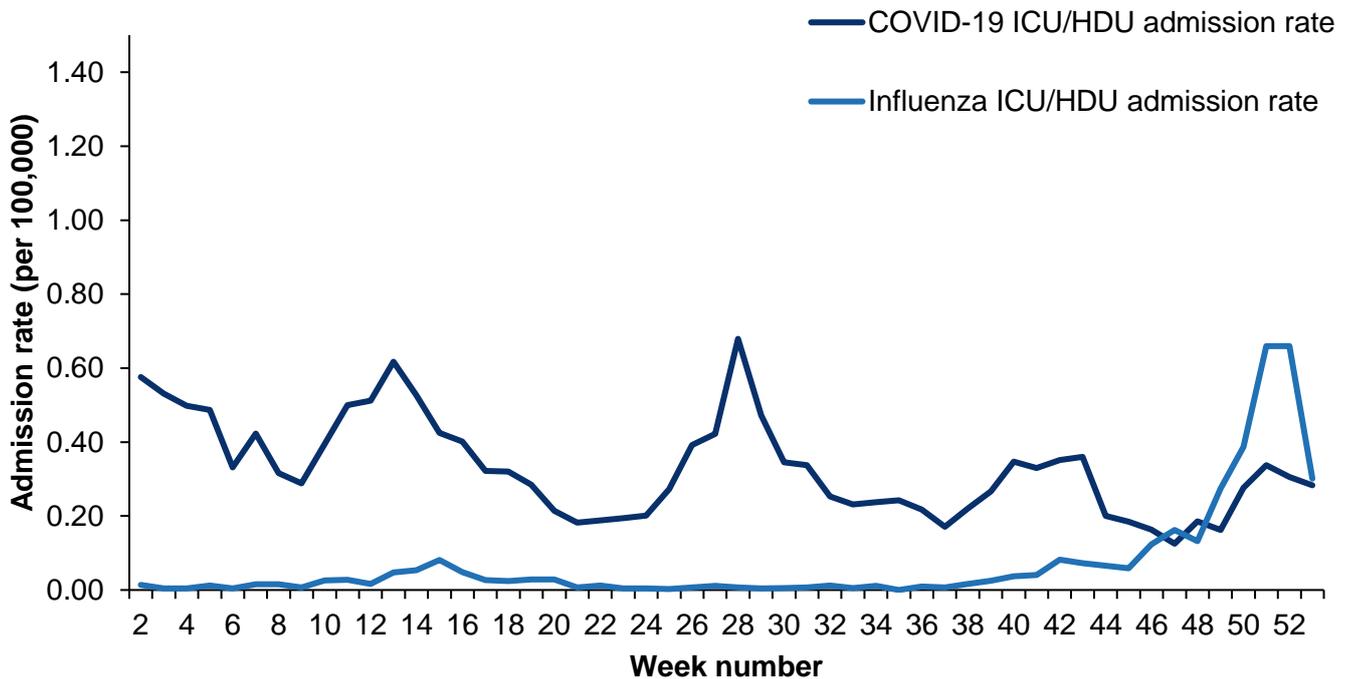

ICU or HDU admissions, SARI Watch

In week 1 (ending 8 January 2023), the overall weekly ICU or HDU admission rates for COVID-19 remains low, decreasing slightly to 0.28 per 100,000, compared to 0.31 per 100,000 the previous week. Note that ICU or HDU admissions rates may represent a lag from admission to hospital to an ICU or HDU ward.

By UKHSA centre, the highest ICU or HDU admission rates for COVID-19 were observed in London. By age group, the highest ICU or HDU admission rates for COVID-19 was observed in the 75 to 84 year olds and over.

In week 1, the overall ICU or HDU rate for influenza was 0.30 per 100,000 compared to 0.66 per 100,000 in the previous week. There were 116 new case report of an ICU or HDU admission for influenza in week 1 (15 influenza A(H1N1)pdm09, 6 influenza A(H3N2), 83 influenza A(not subtyped) and 12 influenza B).

Figure 40: Weekly overall ICU or HDU admission rates of new COVID-19 and influenza positive cases per 100,000 population reported through SARI Watch, England

- * Influenza ICU or HDU admission rate based on 91 NHS trusts for week 1
- * COVID-19 ICU or HDU admission rate based on 79 NHS trusts for week 1
- * SARI Watch data is provisional

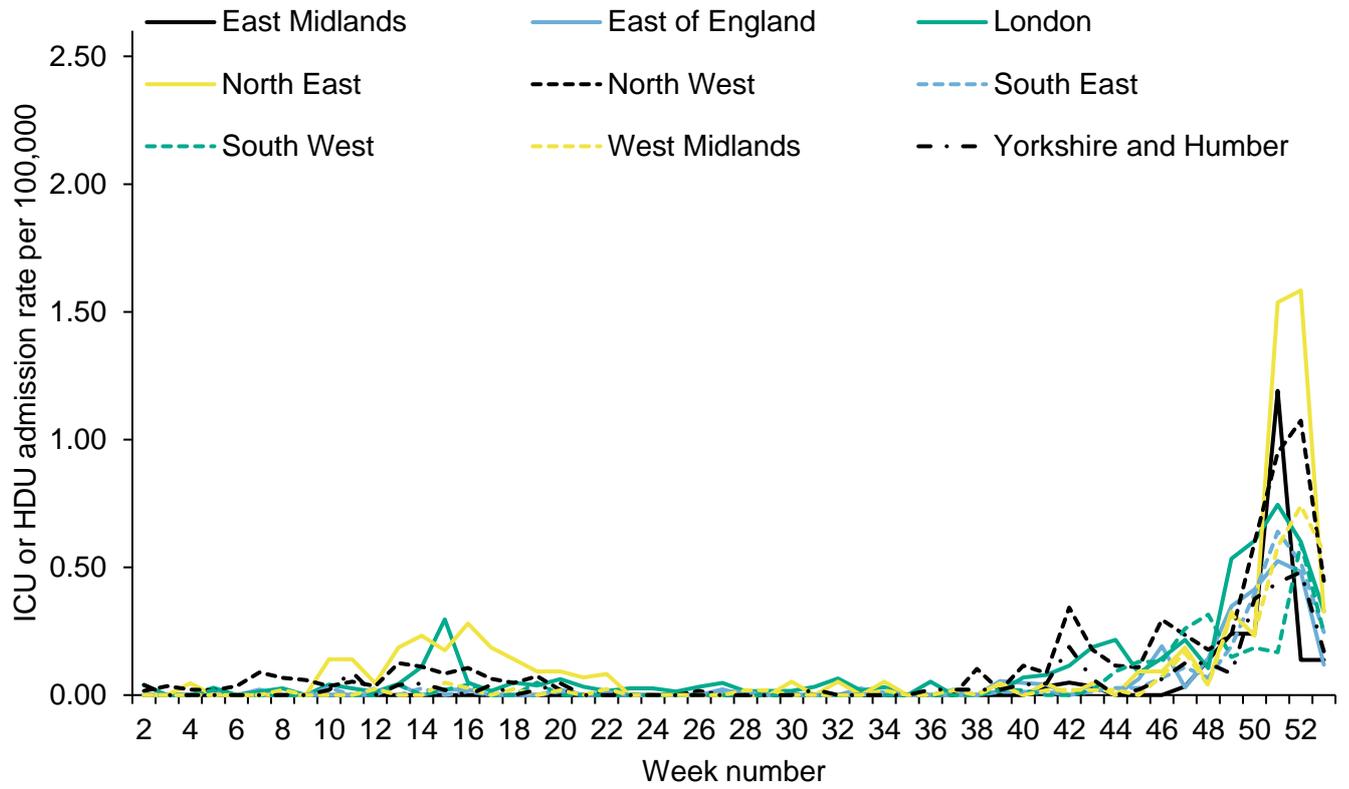

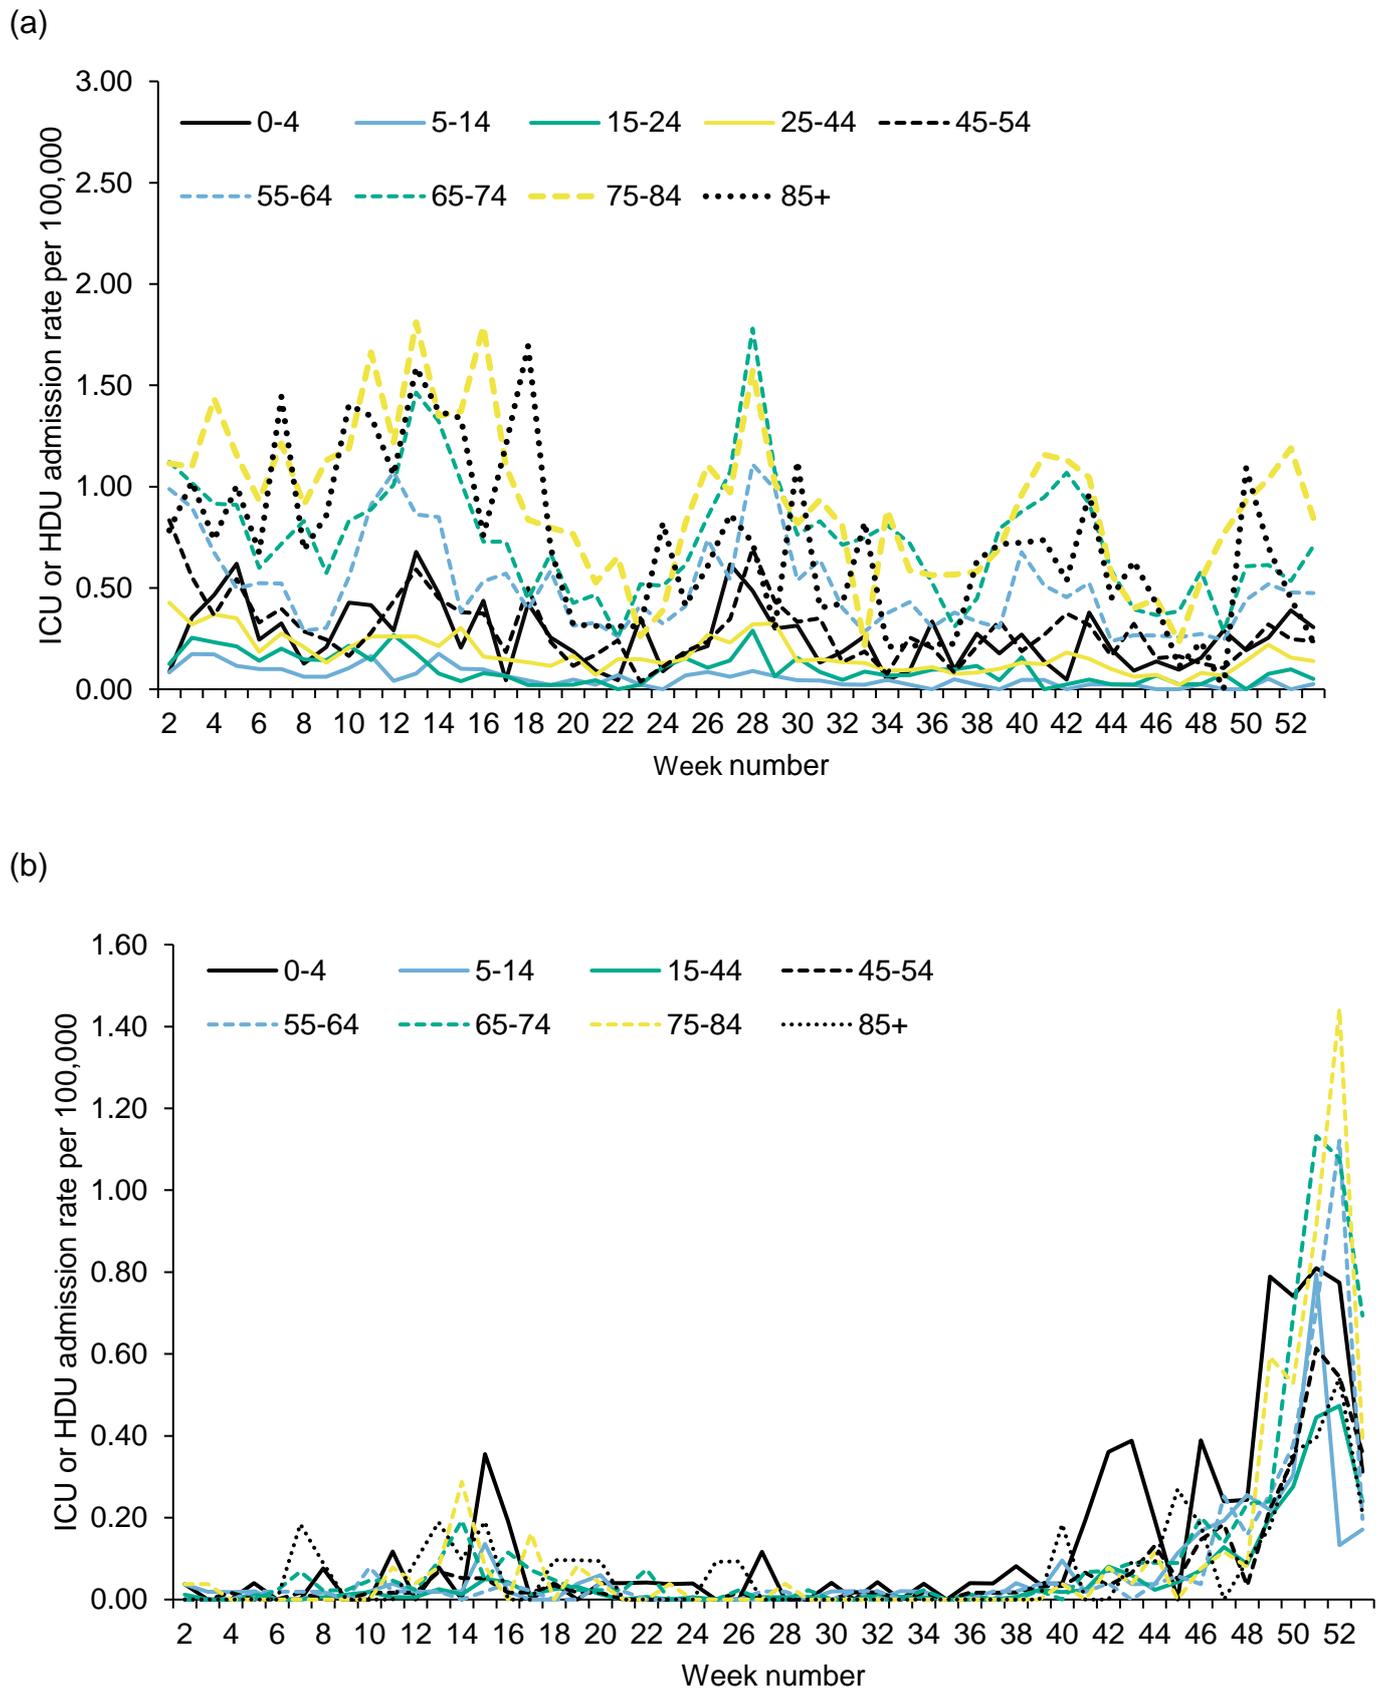

Figure 44: Weekly ICU or HDU admission rate by age group for new (a) COVID-19 positive cases and (b) influenza, reported through SARI Watch

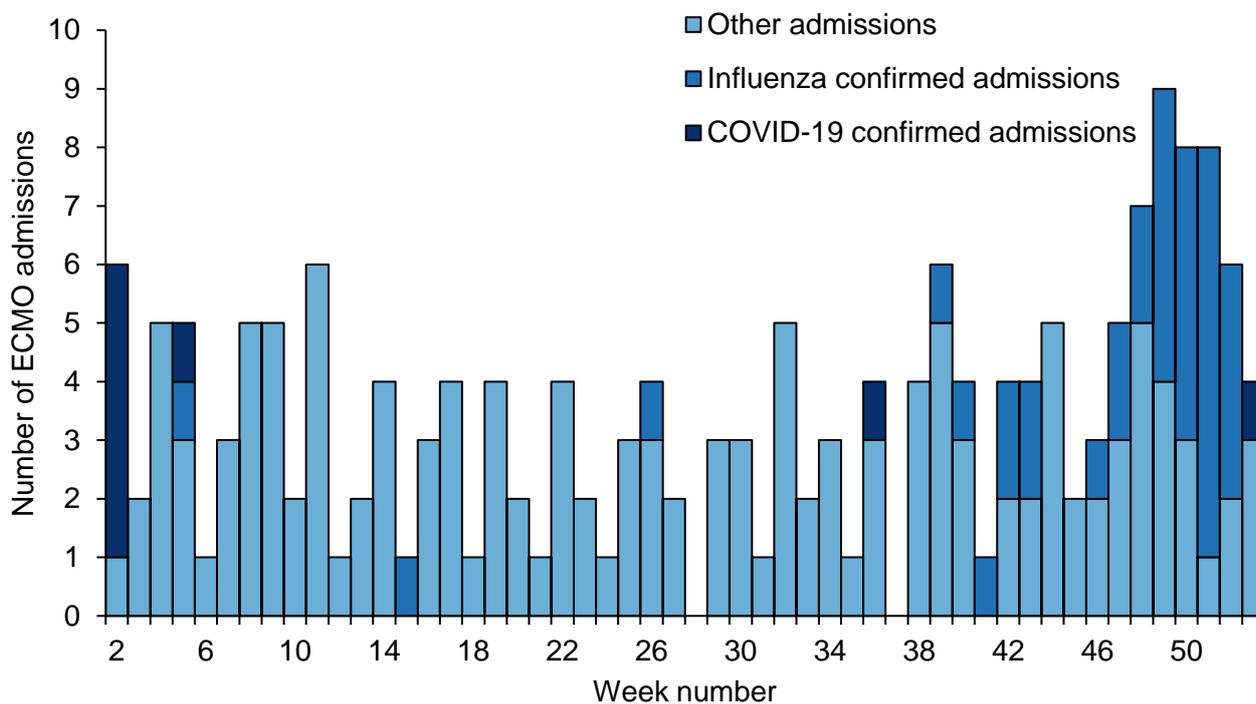

ECMO, SARI Watch

There were 4 new laboratory confirmed ECMO admissions reported in week 1 from the 7 Severe Respiratory Failure (SRF) centres in the UK (Figure 45). 1 was due to COVID-19. No new influenza admissions were reported.

Figure 45: Laboratory confirmed ECMO admissions (COVID-19, influenza and non-COVID-19 confirmed) to Severe Respiratory Failure centres in the UK

* SARI Watch data is provisional

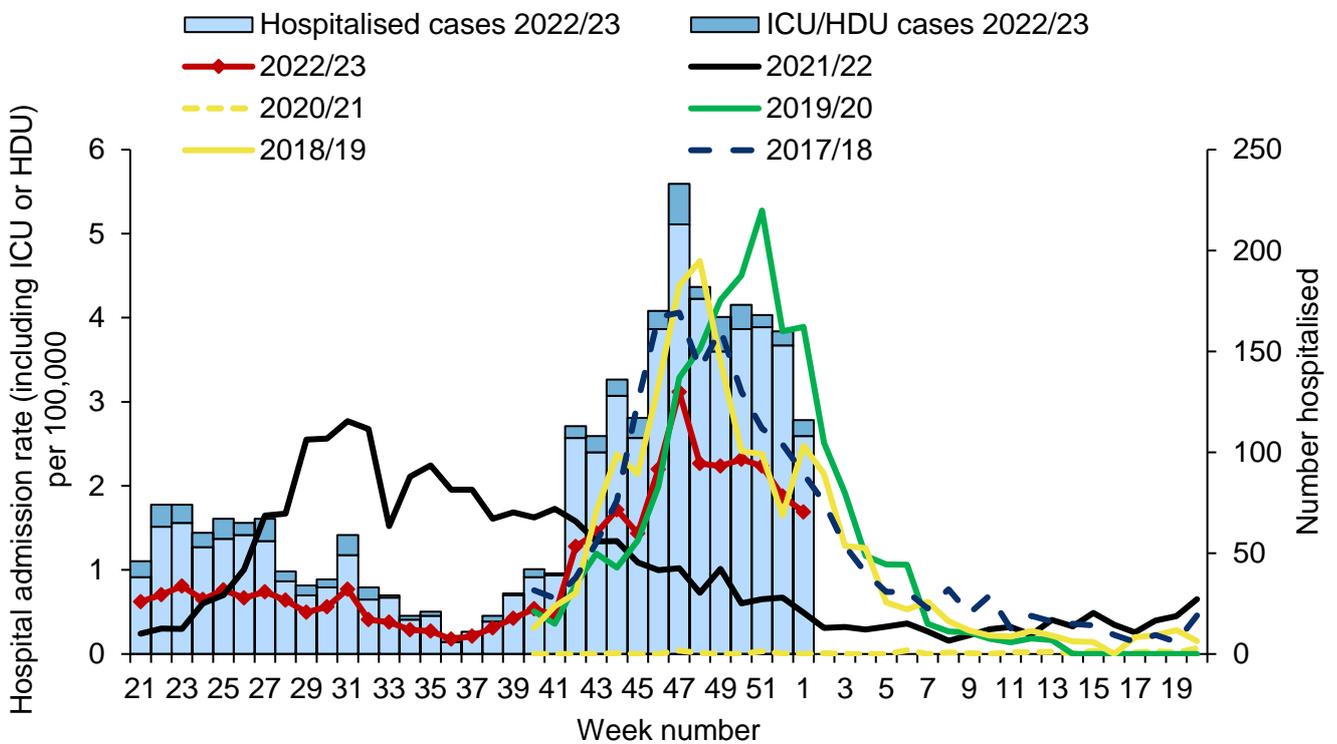

RSV admissions, SARI Watch

Data on hospitalisations, including ICU or HDU admissions, with respiratory syncytial virus (RSV) are shown below. RSV SARI Watch surveillance is sentinel.

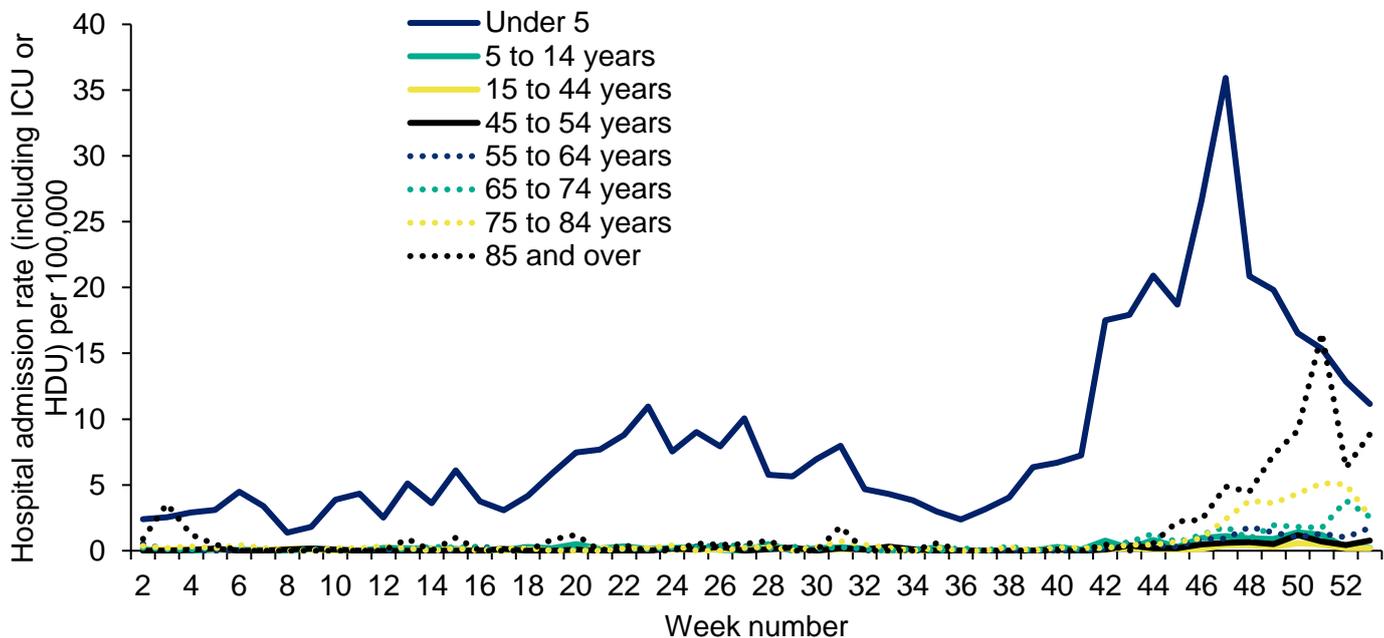

In week 1, the overall hospital admission rate for RSV was 1.69 per 100,000 compared to 1.88 per 100,000 in the previous week. The highest rates are seen in the under 5 year olds (11.2 per 100,000).

Figure 46: Weekly overall hospital admission rates (including ICU or HDU) of RSV positive cases per 100,000 population reported through SARI Watch, England

* Please note that in previous seasons, RSV SARI Watch surveillance has run from week 40 to week 20. In the 2020 to 2021 season onwards this was extended to run throughout the year, to allow for surveillance of out-of-season trends

Figure 47: Weekly hospitalisation (including ICU or HDU) admission rates by age group for new RSV cases reported through SARI Watch, England

* Please note that rates are based on the number of hospitalised cases divided by the Trust catchment population, multiplied by 100,000

* SARI Watch data is provisional

Emergency Department attendances, Syndromic surveillance

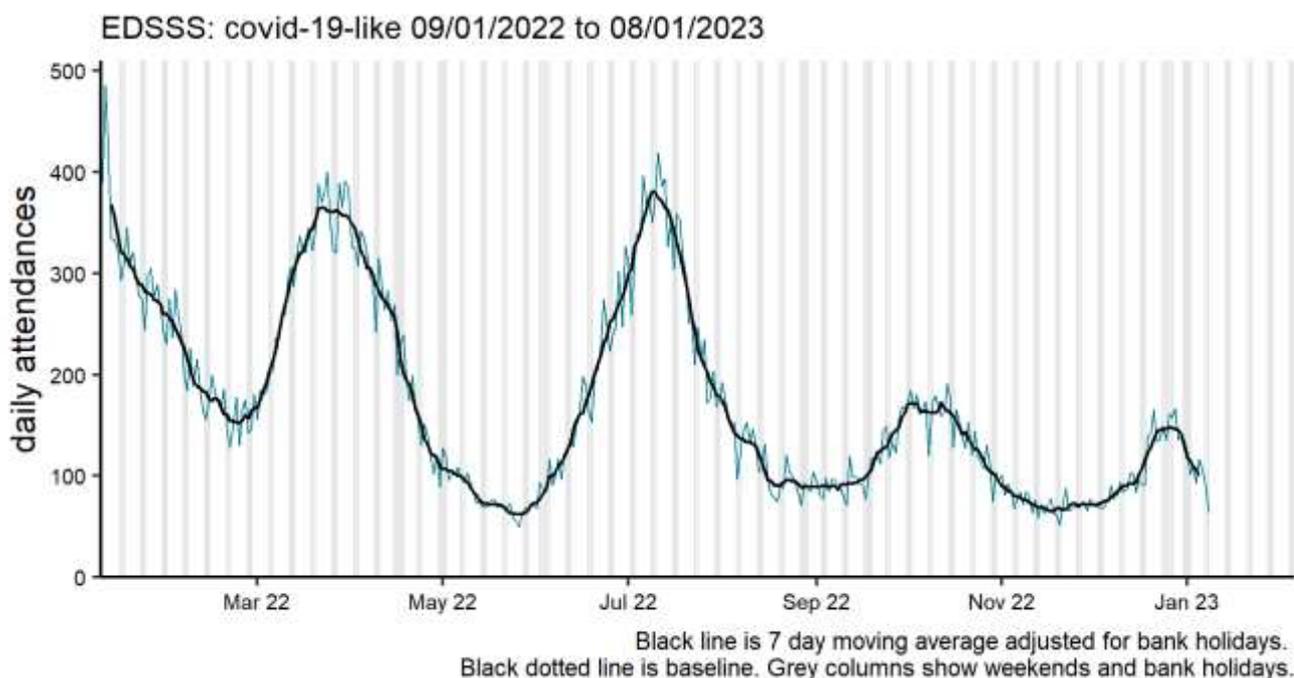

The [Emergency Department Syndromic Surveillance System \(EDSSS\)](#) monitors the daily visits in a network of emergency departments across England.

During week 1, emergency department attendances for acute respiratory infection decreased nationally and in all age groups. Emergency department attendances for acute bronchiolitis decreased nationally. Emergency department attendances for influenza-like illness decreased nationally, across all ages and regions. Emergency department attendances for covid-like illness decreased nationally. (Figures 48, 49, 50 and 51).

Please note: the COVID-19-like ED indicator is an underestimation of the number of COVID-19 attendances as it only includes attendances with a COVID-19-like diagnosis as their primary diagnosis. The EDSSS COVID-19-like indicator should therefore be used to monitor trends in ED attendances and not to estimate actual numbers of COVID-19 ED attendances. Further information about these caveats is available from the [Emergency Department Syndromic Surveillance](#) bulletin.

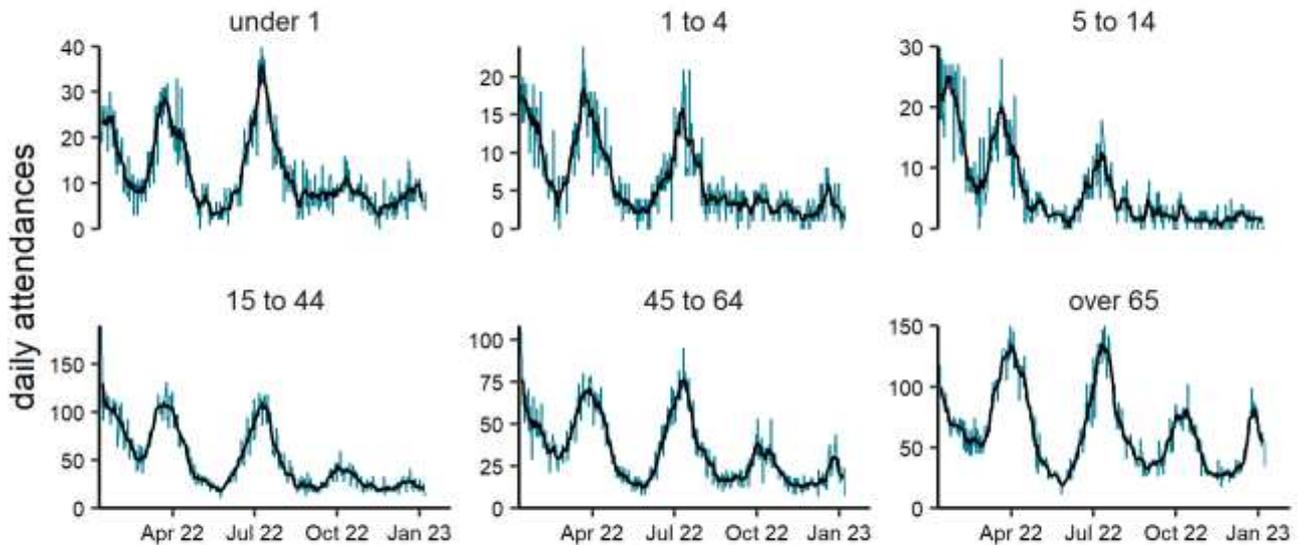

Figure 48: Daily ED attendances for COVID-19-like infections, England (a) nationally, (b) by age group and (c) by UKHSA centre

Mortality surveillance

COVID-19 deaths

COVID-19 related deaths by the 28 day definition are reported below. This metric includes a death in a person with a positive COVID-19 test who died within (equal to or less than) 28 days of the first positive specimen date in the most recent episode of infection.

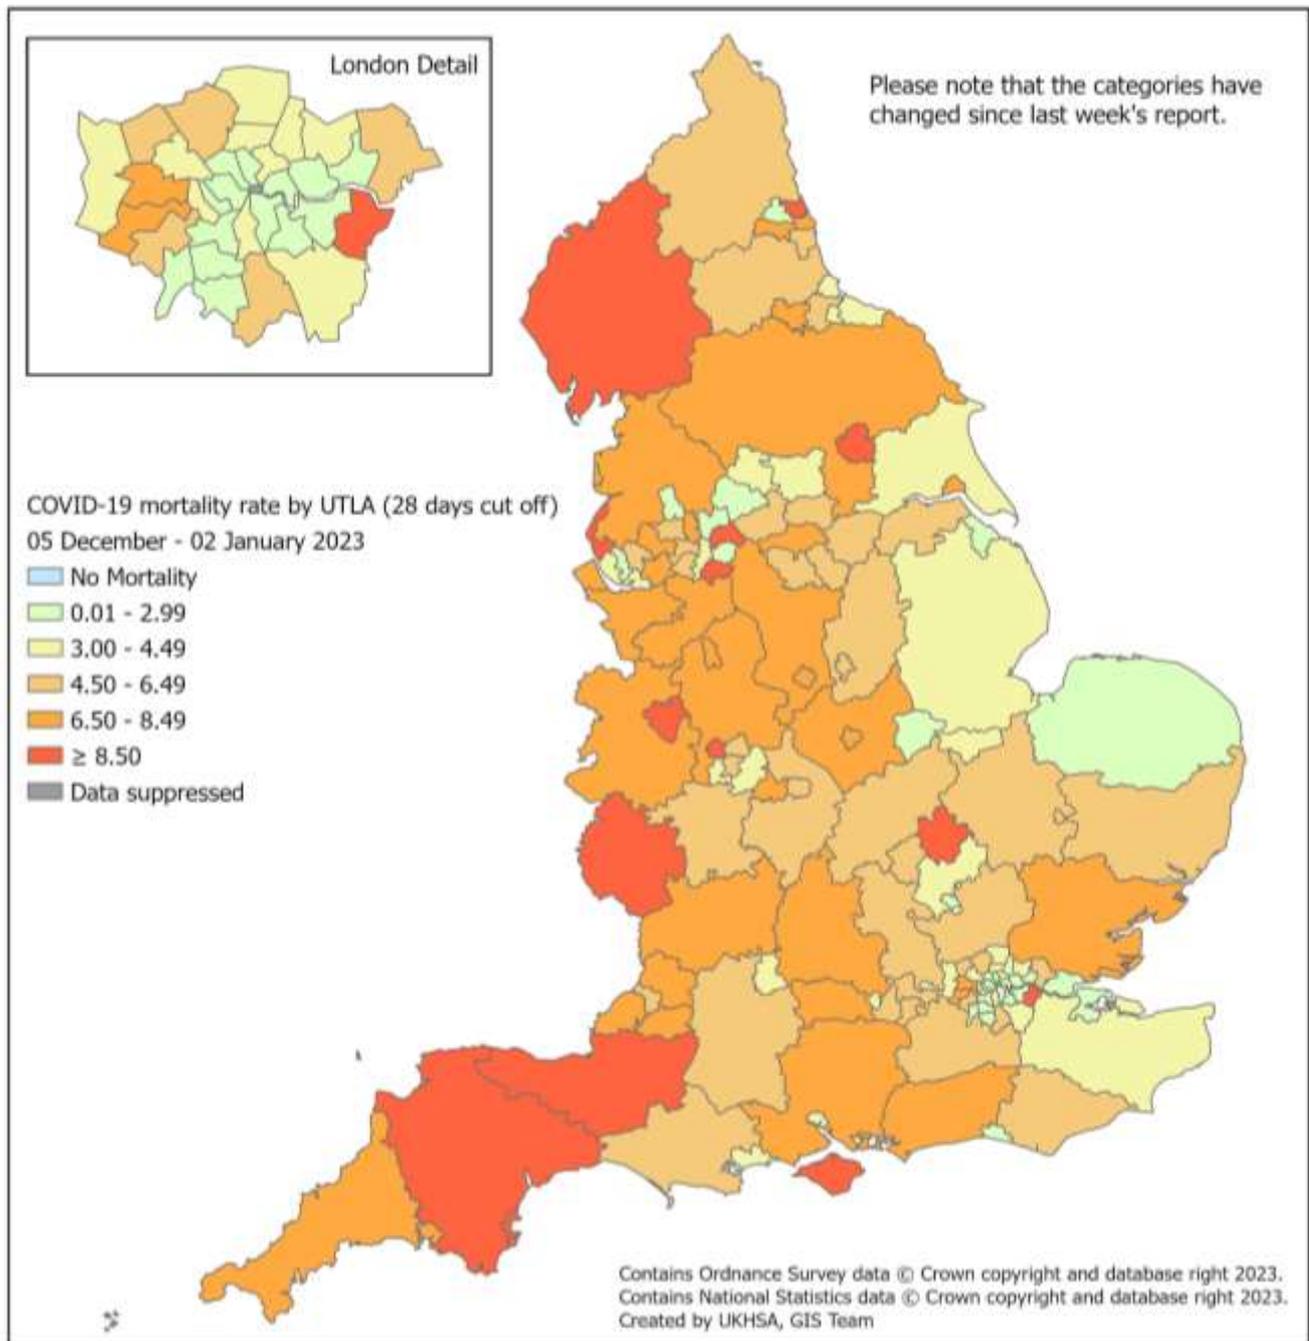

Figure 52: Number of deaths by week of death and time since a positive COVID-19 test (28 day definition), England

* Vertical dotted line indicates the end of provision of free universal testing for the general public in England, as outlined in the plan for [living with COVID-19](#).

* Data is shown by the week of death. This gives the most accurate analysis of this time progression, however, for the most recent weeks' numbers more deaths are expected to be registered therefore this should be interpreted with caution

Figure 53: Cumulative mortality rate of COVID-19 cases per 100,000 population tested under Pillars 1 and 2 for the weeks 48 to 52 by 28 day definition

Daily excess all-cause mortality (England)

Deaths occurring from 1 January 2020 to 4 January 2023 were assessed to calculate the daily excess above a baseline using age-group and region specific all cause deaths as provided daily by the General Register Office (GRO). The deaths were corrected to allow for delay to registration based on past data on these delays. The baseline until November 2020 was from the same day of the year in the previous 5 years plus or minus 7 days with an extrapolated time trend. The baseline from December 2020 to March 2021 only uses the same days plus or minus 7 days from the past 3 low flu years with no trend, and the baseline from April 2021 onwards is set to be the same as the previous year's baseline. Along with the baseline 2 and 3 standard deviation (SD) limits shown (Figure 54).

Weeks in which at least 2 days exceeded the 3SD threshold are shown in Table 3 and the daily difference from the baseline by age and region is given in Figures 55 and 56.

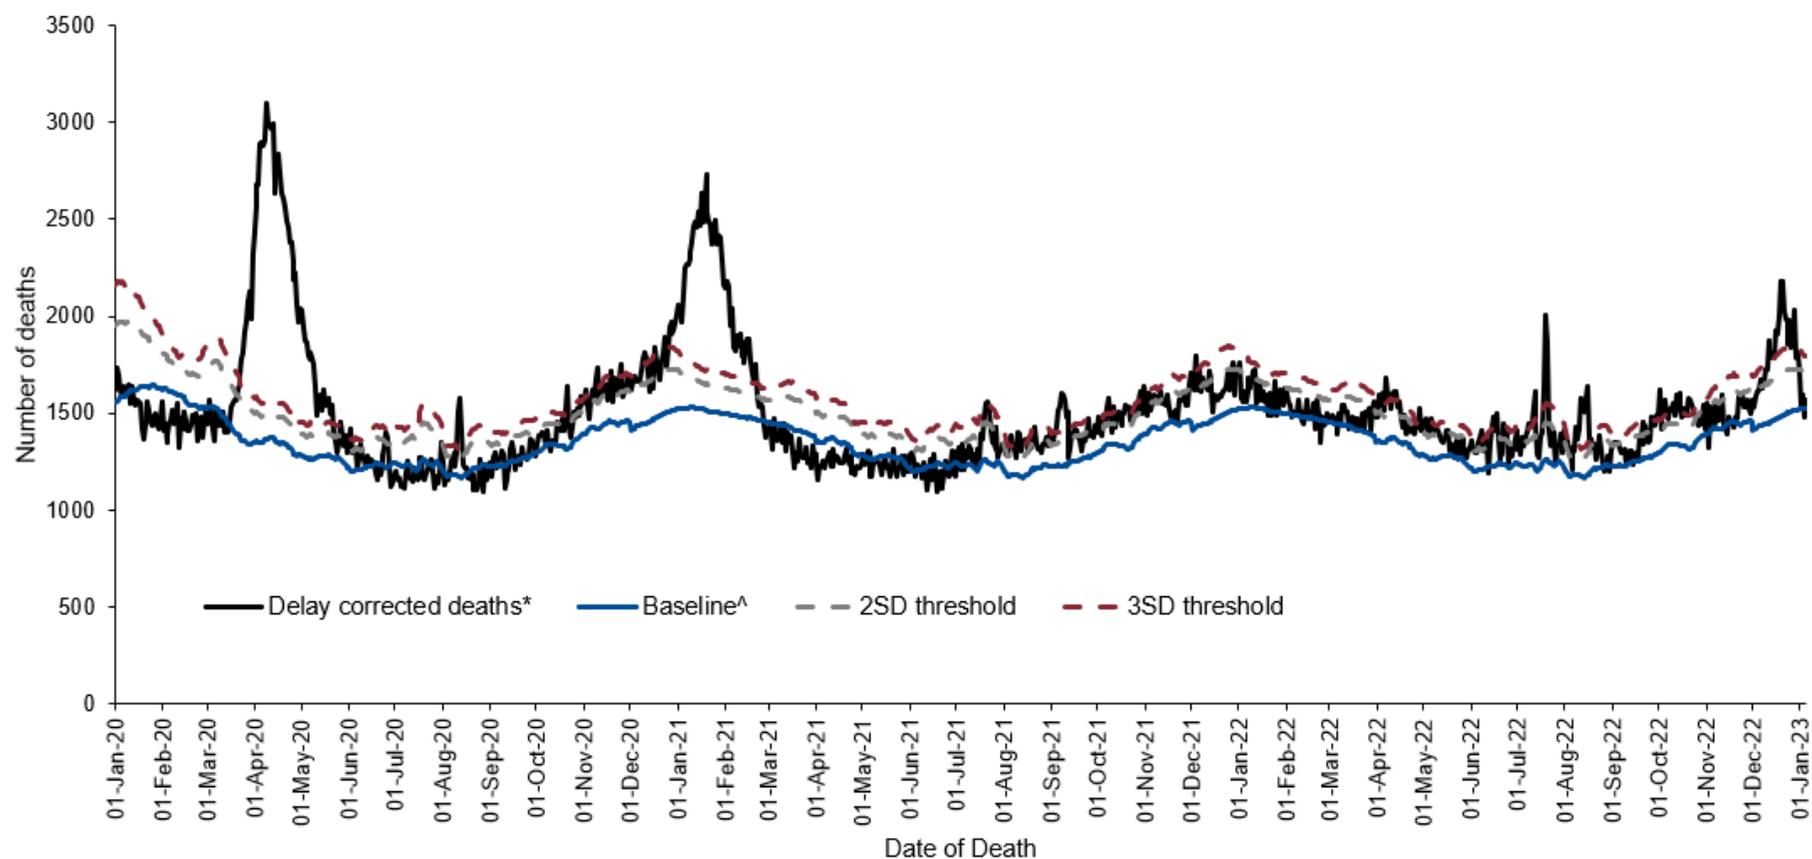

Note that as this data is by date of death with delay corrections, numbers are subject to change each week, particularly for more recent days. The deaths in the most recent week in this report may be underestimated due to the new year bank holiday, leading to greater delays. The current week's model supersedes models presented in previous week.

Excess all-cause mortality was observed in week 52.

Note that level 3 heat-health alerts were issued for June 17 to 18, July 11 to 21, and August 9 to 16 2022, and a level 4 heat-health alert issued for July 18 to 19 2022.

Other measures of excess mortality published by UKHSA are the [Fingertips excess mortality in England report](#), which uses ONS death registration data and [the all-cause mortality surveillance report](#), which uses the EuroMOMO model to measure excess deaths.

Figure 54: Daily excess all-cause deaths in all ages, England, 1 January 2020 to 4 January 2023

^Baseline calculation:

January to November 2020: same day in previous 5 years plus or minus 1 week with a linear trend.

December 2020 to March 2021: past 3 low flu years plus or minus 2 weeks, no trend.

March 2021 onwards: same baseline as 2020

*Corrected for delay to registration from death

Table 3: Excess all-cause deaths by (a) age group and (b) UKHSA centres, England

Microbiological surveillance

Influenza virus characterisation

UKHSA characterises the properties of influenza viruses through one or more tests, including genome sequencing (genetic analysis) and haemagglutination inhibition (HI) assays (antigenic analysis). These data are used to compare how similar the currently circulating influenza viruses are to the strains included in seasonal influenza vaccines, and to monitor for changes in circulating influenza viruses. The interpretation of genetic and antigenic data sources is complex due to a number of factors, for example, not all viruses can be cultivated in sufficient quantity for antigenic characterisation, so that viruses with sequence information may not be able to be antigenically characterised as well. Occasionally, this can lead to a biased view of the properties of circulating viruses, as the viruses which can be recovered and analysed antigenically, may not be fully representative of majority variants, and genetic characterisation data does not always predict the antigenic characterisation.

Between week 40 2022 and week 2 2023, the UKHSA Respiratory Virus Unit have genetically characterised, by sequencing of the haemagglutinin (HA) gene, 1,158 influenza A viruses (690 A(H3N2) and 468 A(H1N1)pdm09 viruses) and 12 influenza B viruses.

The 690 influenza A(H3N2) viruses genetically characterised, all belong in the genetic subclade 3C.2a1b.2a.2. The Northern Hemisphere 2022/23 influenza A(H3N2) vaccine strain (an A/Darwin/9/2021-like virus) also belongs in this 3C.2a1b.2a.2 genetic subclade.

The 468 influenza A(H1N1)pdm09 viruses characterised to date this season, all belong in genetic subgroup 6B.1A.5a.2. The Northern Hemisphere 2022/23 influenza A(H1N1)pdm09 vaccine strain (an A/Victoria/2570/2019-like virus) also belongs in genetic subclade 6B.1A.5a, within the 6B.1A.5a.2 cluster.

Twelve influenza B/Victoria lineage viruses have been genetically characterised, all belonging in subclade V1A3, within the subgroup V1A3a.2. The Northern Hemisphere 2022/23 influenza B/Victoria lineage vaccine strain (a B/Austria/1359417/2021-like virus) also belongs in this V1A3a.2 subclade/group.

The Respiratory Virus Unit has confirmed by genome sequencing the detection of live attenuated influenza vaccine (LAIV) viruses in one influenza A positive sample and 4 influenza B positive samples collected since week 40, all from children aged 2 to ≤16 years of age.

Influenza antiviral susceptibility

Influenza positive samples are genome sequenced and screened for mutations in the virus neuraminidase (NA) and the cap-dependent endonuclease (PA) genes known to confer neuraminidase inhibitor or baloxavir resistance, respectively. The samples tested are routinely obtained for surveillance purposes, but diagnostic testing of patients suspected to be infected with antiviral-resistant virus is also performed.

Influenza virus sequences from samples collected between weeks 40 2022 and 2 2023 have been analysed. No viruses with known markers of resistance to neuraminidase inhibitors were detected in 624 A(H3N2), 436 A(H1N1)pdm09 and 12 Influenza B NA sequences analysed. No viruses with known markers of resistance to baloxavir marboxil were detected in 513 A(H3N2), 339 A(H1N1)pdm09 and 11 influenza B PA sequences analysed.

Table 4: Antiviral susceptibility of influenza positive samples tested at UKHSA-RVU

(Sub)type	Neuraminidase Inhibitors		Baloxavir	
	Susceptible	Reduced Susceptibility	Susceptible	Reduced Susceptibility
A(H3N2)	624	0	513	0
A(H1N1)pdm09	436	0	339	0
B/Victoria-lineage	12	0	11	0

SARS-CoV-2 variants

This section is updated fortnightly.

UKHSA conducts genomic surveillance of SARS-CoV-2 variants.

This section provides an overview of new and current circulating variants in England.

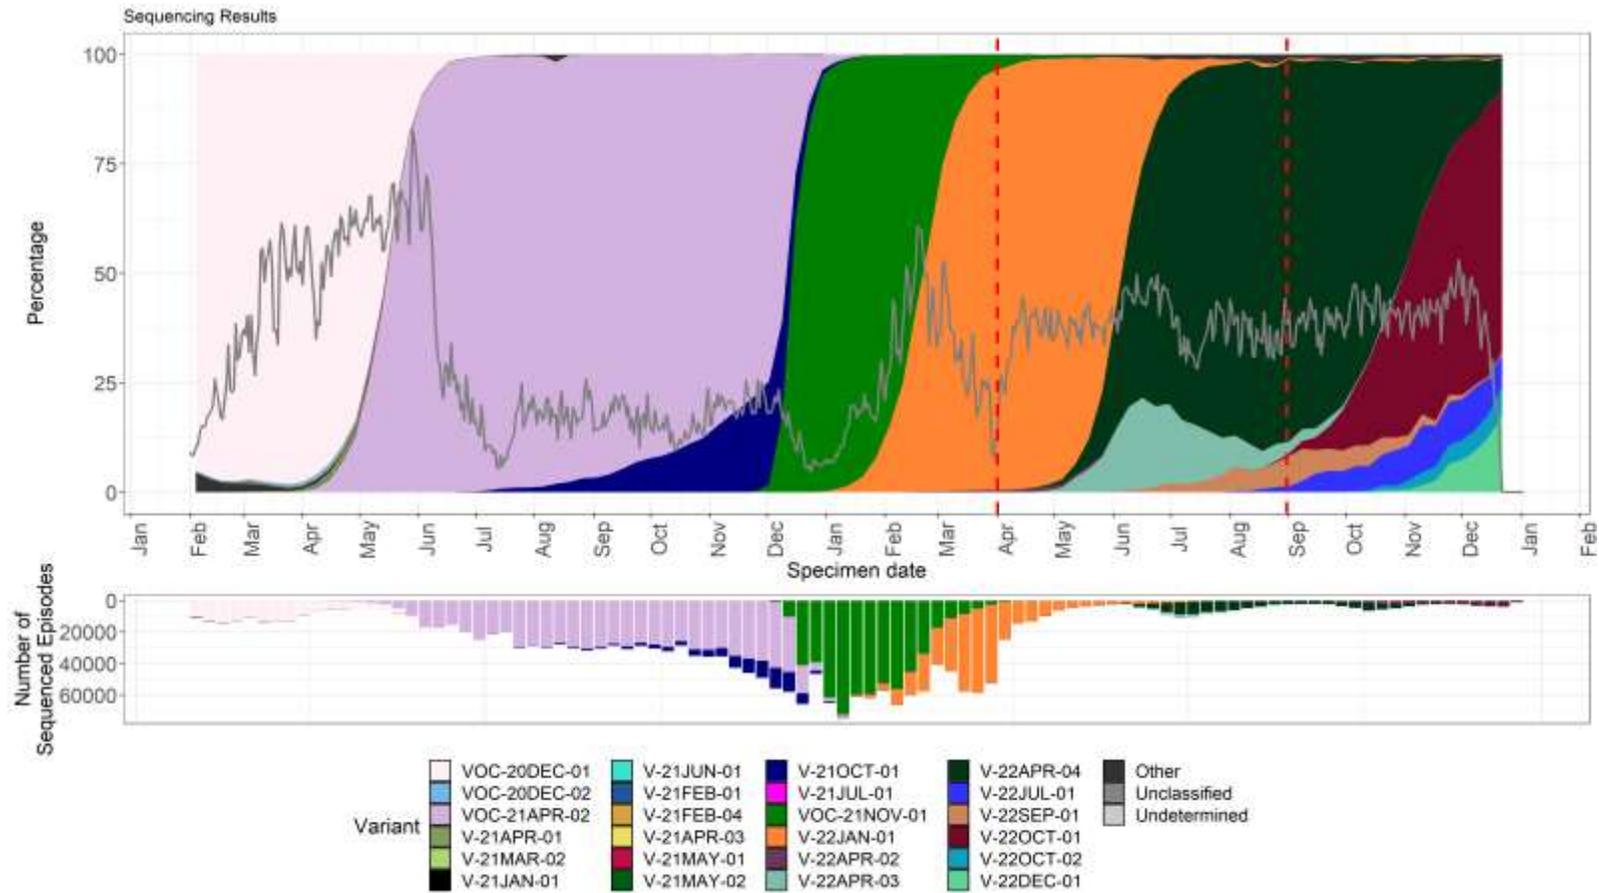

Detailed surveillance of particular variants of concerns can be found in recent [technical briefings](#).

Information on whole genome sequencing coverage can be found in the accompanying slide set.

The prevalence of different UKHSA-designated variants amongst sequenced episodes is presented in Figure 57.

Of the sequenced episodes from 19 December 2022 to 25 December 2022, 1% were classified BA.4.6 (V-22SEP-01), 8% were BA.5 (V-22APR-04), 59% were BQ.1 (V-22OCT-01), 7% were BA.2.75 (V-22JUL-01), 7% were as XBB (V-22OCT-02) and 18% were CH.1.1 (V-22DEC-01).

Figure 57. Prevalence of SARS-CoV-2 variants amongst available sequences episodes for England from 1 February, as of 3 January 2023

The grey line indicates proportion of cases sequenced.

The vertical dashed lines (red) denote changes in policies:

- April line denotes the start of England's 'Living with COVID' Plan.
- End of August line denotes the change in asymptomatic testing

Note: Recombinants such as XD, are not specified but are largely within the 'Other' group currently as numbers are too small.

As of week 51 2022, BQ.1 continues to be the predominant circulating variant in England (Table 5).

Table 5. Total distribution of SARS-CoV-2 variants detected in England in the last 12 weeks, up to week 51 (week ending 25 December 2022)

Variant	Other names by which this variant is known	Total confirmed (sequencing) cases in the last 12 weeks	Last reported specimen date
VOC-21APR-02	Delta	1	04/11/2022
VOC-21NOV-01	Omicron BA.1	12	17/12/2022
V-22JAN-01	Omicron BA.2	192	21/12/2022
V-22APR-03	Omicron BA.4	128	20/12/2022
V-22APR-04	Omicron BA.5	18709	21/12/2022
V-22JUL-01	Omicron BA.2.75	3543	22/12/2022
V-22SEP-01	Omicron BA.4.6	1160	20/12/2022
V-22OCT-01	Omicron BQ.1	17931	21/12/2022
V-22OCT-02	Omicron XBB	1180	21/12/2022
V-22DEC-01	Omicron CH.1.1	1881	22/12/2022

*Sequencing data has a lag of approximately two weeks therefore the presented numbers should be interpreted in this context

*Cumulative numbers may be revised up or down as a results of reclassification of results, re-infections and changes to diagnostic tests, new variants, or public health management levels

*Confirmed individuals are confirmed COVID-19 cases with a validated sequencing result meeting the confirmed case definitions

Antimicrobial susceptibility

Table 6 shows in the 12 weeks up to week 52 2022, the proportion of all lower respiratory tract isolates of *Streptococcus pneumoniae*, *Haemophilus influenzae*, *Staphylococcus aureus*, MRSA (Methicillin-resistant *Staphylococcus aureus*) and MSSA (methicillin-susceptible *Staphylococcus aureus*) tested and susceptible to antibiotics. These organisms are the important causes of community-acquired pneumonia (CAP), and the choice of antibiotics reflects the British Thoracic Society empirical guidelines for management of CAP in adults.

Table 6: Antimicrobial susceptibility surveillance in lower respiratory tract

Organism	Antibiotic	Specimens tested (N)	Specimens susceptible (%)
<i>S. pneumoniae</i>	Penicillin	2,430	89
	Macrolides	2,758	83
	Tetracycline	2,523	82
<i>H. influenzae</i>	Amoxicillin or ampicillin	12,069	41
	Co-amoxiclav	14,334	47
	Macrolides	3,016	4
	Tetracycline	14,231	98
<i>S. aureus</i>	Methicillin	5,134	92
	Macrolides	6,057	69
MRSA	Clindamycin	286	47
	Tetracycline	337	70
MSSA	Clindamycin	3,452	75
	Tetracycline	4,118	94

* Macrolides = erythromycin, azithromycin and clarithromycin

Data source: UKHSA's SGSS Antimicrobial Resistance (AMR) module, please note that this is different to the data source used in the reports published between weeks 41, 2020 to 5, 2021 inclusive of the 2020 to 2021 influenza season when the SGSS Communicable Disease Report (CDR) module was used instead due to a UKHSA SGSS AMR data infrastructure issue which has now been resolved. Therefore, the above results are not directly comparable to the results reported between weeks 41, 2020 and 5, 2021. The AMR module of SGSS was used during the 2019 to 2020 influenza season. There has been a reduction in the total number of bacterial positive lower respiratory tract clinical samples reported to UKHSA since mid-March 2020.

COVID-19 sero-prevalence surveillance

Since week 42 2021, updates on COVID-19 sero-prevalence estimates have been published in the weekly [COVID-19 vaccine surveillance report](#).

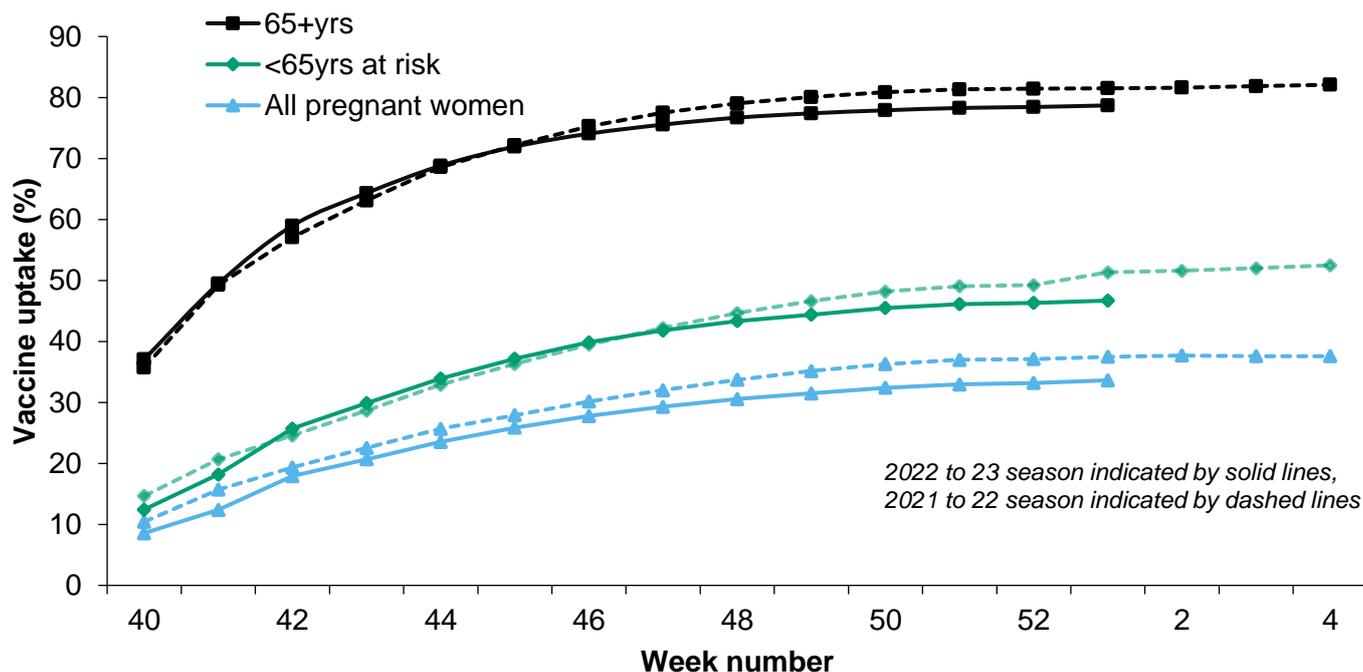

Influenza vaccination

Influenza vaccine uptake in GP patients

Up to week 1 of 2023, in 96.1% of GP practices reporting weekly to ImmForm for the main collection, the provisional proportion of people in England who had received the 2022 to 2023 influenza vaccine in targeted groups was as follows:

- 46.7% in under 65 years in a clinical risk group
- 33.6% in all pregnant women
- 78.7% in all 65 year olds and over
- 39.2% in those aged 50 to 64 who are not in a clinical risk group

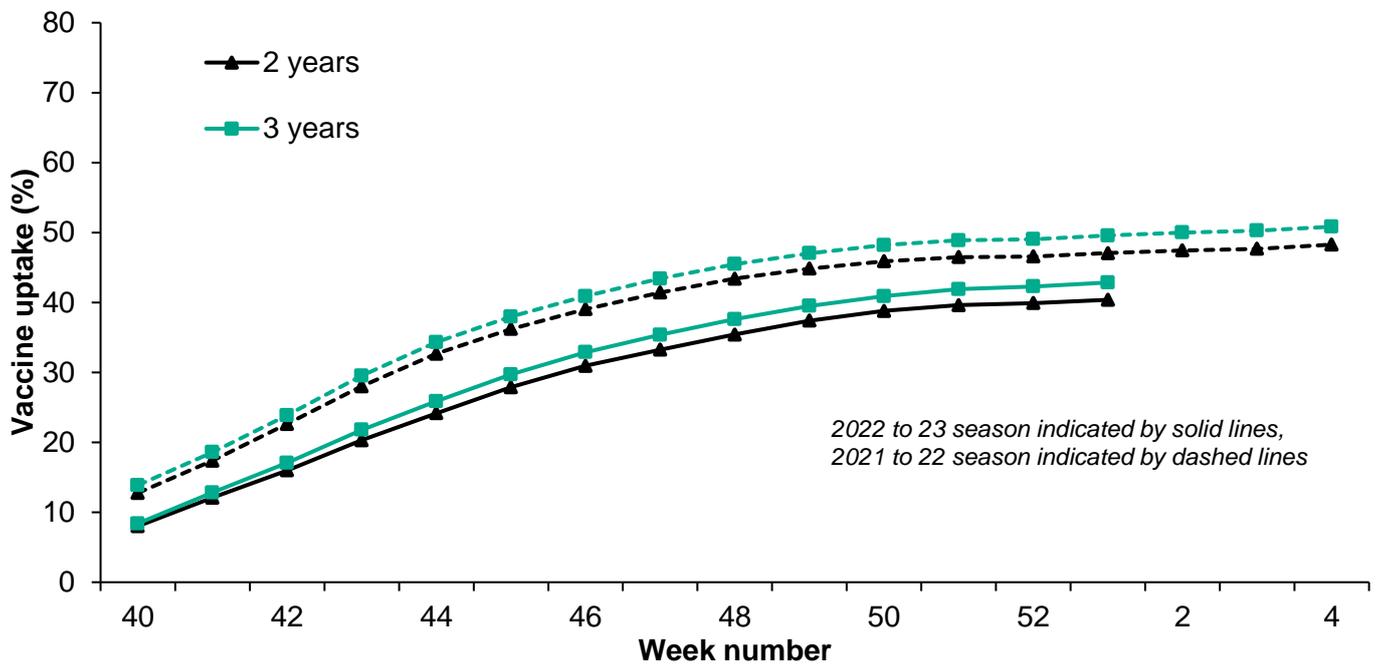

Figure 58: Cumulative weekly influenza vaccine uptake by target group in England

In 2022 to 2023, all 2 and 3 year olds continue to be eligible for influenza vaccination through their GPs. Up to week 1 of 2023, in 98.0% of GP practices reporting weekly to ImmForm for the childhood collection, the provisional proportion of children in England who had received the 2022 to 2023 influenza vaccine in targeted groups was as follows:

- 40.4% in all 2 year olds
- 42.9% in all 3 year olds

Figure 59: Cumulative weekly influenza vaccine uptake in 2 and 3 year olds, in England

COVID-19 vaccination

COVID-19 vaccine uptake in England

COVID-19 vaccinations began in England on 8 December 2020 during week 50 2020 (week ending 13 December 2020). Cumulative data up to week 1 2023 (week ending 8 January 2023) was extracted from the National Immunisation Management Service (NIMS). The data presented this week is the provisional proportion of living people resident in England who had received COVID-19 vaccinations. Individuals vaccinated in England who have a registered address outside of England or where their address, age, or sex is unknown have been excluded. Due to changes in GP practice lists, in order to include newly registered patients and remove those who are no longer resident, there will be slight variation to the figures to reflect those who are currently resident in England.

Age is calculated on the date data is extracted. The weekly vaccine coverage data is extracted on a Tuesday with data capped to the previous Sunday and all backing data is updated each week going back to the start of the programme.

Data is provisional and subject to change following further validation checks. Any changes to historic figures will be reflected in the most recent publication. Please note that numbers published by UKHSA are for public health surveillance purposes only.

Autumn Booster Campaign

Immunity derived from vaccination declines over time and following on from the Spring campaign, the JCVI has recommended an Autumn Booster campaign with the primary objective to boost immunity in those at higher risk from COVID-19 and thereby optimise protection against severe COVID-19, specifically hospitalisation and death, over winter 2022 to 2023.

The Autumn booster data reported below covers any booster dose administered from the 1 September 2022 provided there is at least 3 months from the previous dose. Eligible groups for the Autumn booster campaign are defined in the COVID-19 healthcare guidance [Green Book](#) and include residents in a care home for older adults, staff working in care homes for older adults, frontline health and social care workers, all adults aged 50 years and over, persons aged 5 to 49 years in a clinical risk group, household contacts of people with immunosuppression, and carers.

Table 7 presents coverage as measured against the total population and includes people who are not yet due to have their Autumn booster. It is important that unvaccinated individuals, especially vulnerable adults, receive a primary course of vaccination, irrespective of whether individuals have had previous infection. Table 8 should be interpreted in the context of Table 7 which shows how recently a person who is living and resident in England has been vaccinated either through the primary vaccination campaign or a subsequent booster campaign. This helps

us understand the data in the context of vaccine waning across the whole COVID-19 programme.

By the end of week 1 2023 (week ending 8 2023), 64.3% (14,995,236 out of 23,312,691) of all people aged over 50 years old had been vaccinated with an Autumn booster dose since 1 September 2022, Table 7 and Figure 60. Vaccine uptake of those aged over 80 years old was 82.1% (2,445,278 out of 2,977,904).

Table 7: Provisional cumulative people vaccinated by age with a booster of COVID-19 vaccine from the 1 September 2022 as part of the Autumn booster campaign in England

National	People in NIMS cohort who are living and resident in England	Vaccinated with an Autumn booster since 1 September 2022*	Percentage vaccine uptake
Over 80	2,977,904	2,445,278	82.1
75 to under 80	2,421,482	1,992,455	82.3
70 to under 75	2,730,812	2,152,960	78.8
65 to under 70	3,037,934	2,179,256	71.7
60 to under 65	3,690,425	2,254,227	61.1
55 to under 60	4,202,031	2,177,871	51.8
50 to under 55	4,252,103	1,793,189	42.2
Total aged 50 and over	23,312,691	14,995,236	64.3

*Autumn booster defined as any additional dose of vaccine after a 2 dose primary course provided there is an interval of at least 3 months, and it is given since the 1 September 2022.

Figure 60: Cumulative weekly COVID-19 vaccine uptake by age in those who are living and resident in England for those vaccinated with an Autumn booster since 1 September 2022

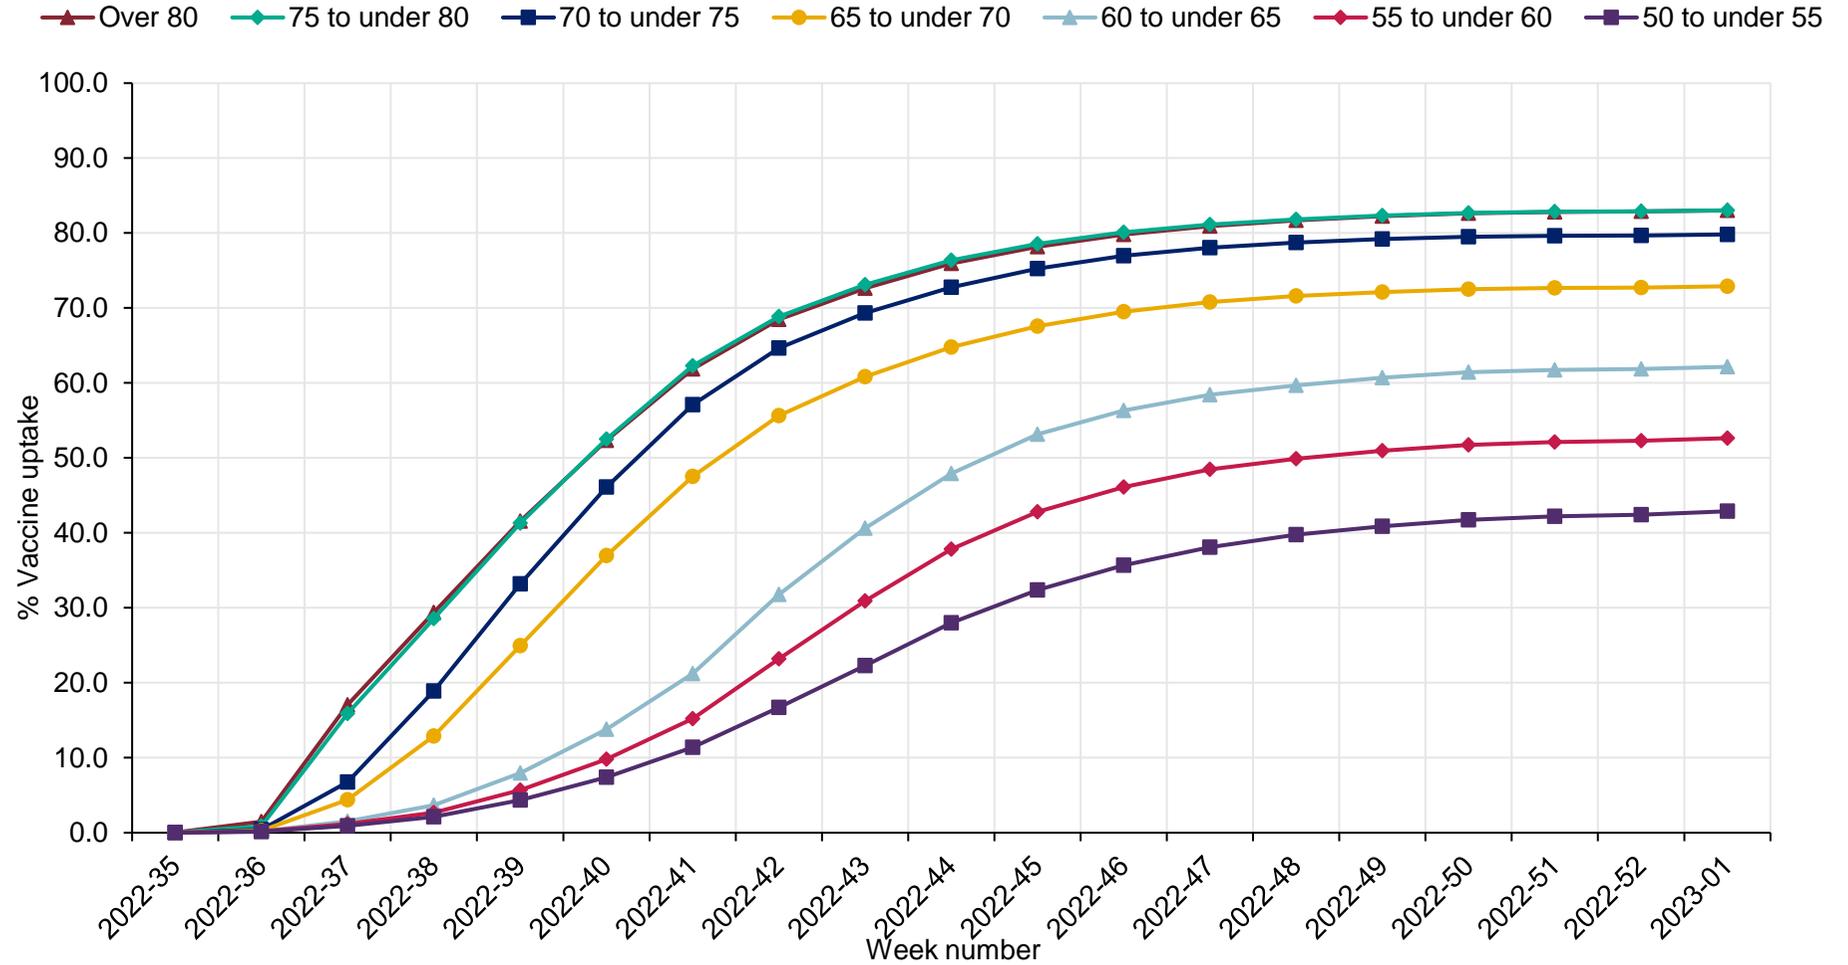

Table 8 presents data by eligibility at the end of December 2022 for the autumn booster campaign if they have completed a primary course of 2 doses and are at least 3 months (84 days) from their previous dose.

Table 8: Provisional cumulative people vaccinated with an autumn booster COVID-19 vaccine against those eligible by the end of December 2022

Age at end of December	Eligible by the end of December	Of those eligible by the end of December, numbers vaccinated	Percentage vaccine uptake eligible end of December
Over 80	2,815,940	2,434,682	86.5
75 to under 80	2,293,862	1,986,805	86.6
70 to under 75	2,540,971	2,152,652	84.7
65 to under 70	2,757,248	2,177,565	79.0
60 to under 65	3,284,686	2,253,101	68.6
55 to under 60	3,659,780	2,178,782	59.5
50 to under 55	3,580,637	1,799,361	50.3
Total aged 50 and over	20,933,124	14,982,948	71.6

Please note that this uses a different age cut off definition to the rest of the report and is therefore not a subset of other tables.

Eligible population figures in this table do not include those who are aged 50 and over and have not been vaccinated; unvaccinated people are taken into consideration in the coverage tables above. This table is based on those who have been vaccinated and may include those who are no longer resident in England or have an unknown address.

Proportion of people vaccinated by time since last vaccination

Table 9: Provisional cumulative people vaccinated with any dose of COVID-19 vaccine in the last 3 months, 3 to 6 months and vaccinated more than 6 months ago

National	People in NIMS cohort who are living and resident in England	Vaccinated in the last 3 months (84 days)		Vaccinated 3 to 6 months ago (85 to 168 days)		Vaccinated 6 months ago (169 or more days)	
		Numbers vaccinated	Percentage vaccinated	Numbers vaccinated	Percentage vaccinated	Numbers vaccinated	Percentage vaccinated
Over 80	2,977,904	640,666	21.5	1,826,304	61.3	380,508	12.8
75 to under 80	2,421,482	515,078	21.3	1,496,615	61.8	305,656	12.6
70 to under 75	2,730,812	635,227	23.3	1,530,733	56.1	401,666	14.7
65 to under 70	3,037,934	785,827	25.9	1,406,959	46.3	604,146	19.9
60 to under 65	3,690,425	1,519,193	41.2	749,837	20.3	1,068,957	29.0
55 to under 60	4,202,031	1,580,270	37.6	614,061	14.6	1,532,405	36.5
50 to under 55	4,252,103	1,342,300	31.6	468,882	11.0	1,847,425	43.4
45 to under 50	3,962,261	307,470	7.8	266,899	6.7	2,635,473	66.5
40 to under 45	4,453,464	238,090	5.3	217,524	4.9	2,934,517	65.9
35 to under 40	4,787,447	201,943	4.2	188,155	3.9	3,038,492	63.5
30 to under 35	4,966,994	179,128	3.6	166,392	3.3	3,064,326	61.7
25 to under 30	4,645,049	136,787	2.9	137,536	3.0	2,842,533	61.2
20 to under 25	3,954,358	96,096	2.4	109,145	2.8	2,599,884	65.7
18 to under 20	1,426,524	31,972	2.2	41,616	2.9	929,358	65.1
16 to under 18	1,420,726	40,670	2.9	51,900	3.7	803,563	56.6
12 to under 16	2,997,149	56,251	1.9	118,291	3.9	1,277,337	42.6
5 to under 12	5,107,330	97,702	1.9	216,736	4.2	238,057	4.7

Table 9 is presented to provide an overview of how recently a person has been vaccinated either through the primary vaccination campaign or subsequent booster campaigns. This helps us understand the data in the context of vaccine waning across the whole COVID-19 programme. Breakdowns by Ethnicity, and IMD, by age can be found in the backing tables.

Figure 61: Provisional cumulative people vaccinated with any dose of COVID-19 vaccine in the last 3 months, 3 to 6 months and vaccinated more than 6 months ago

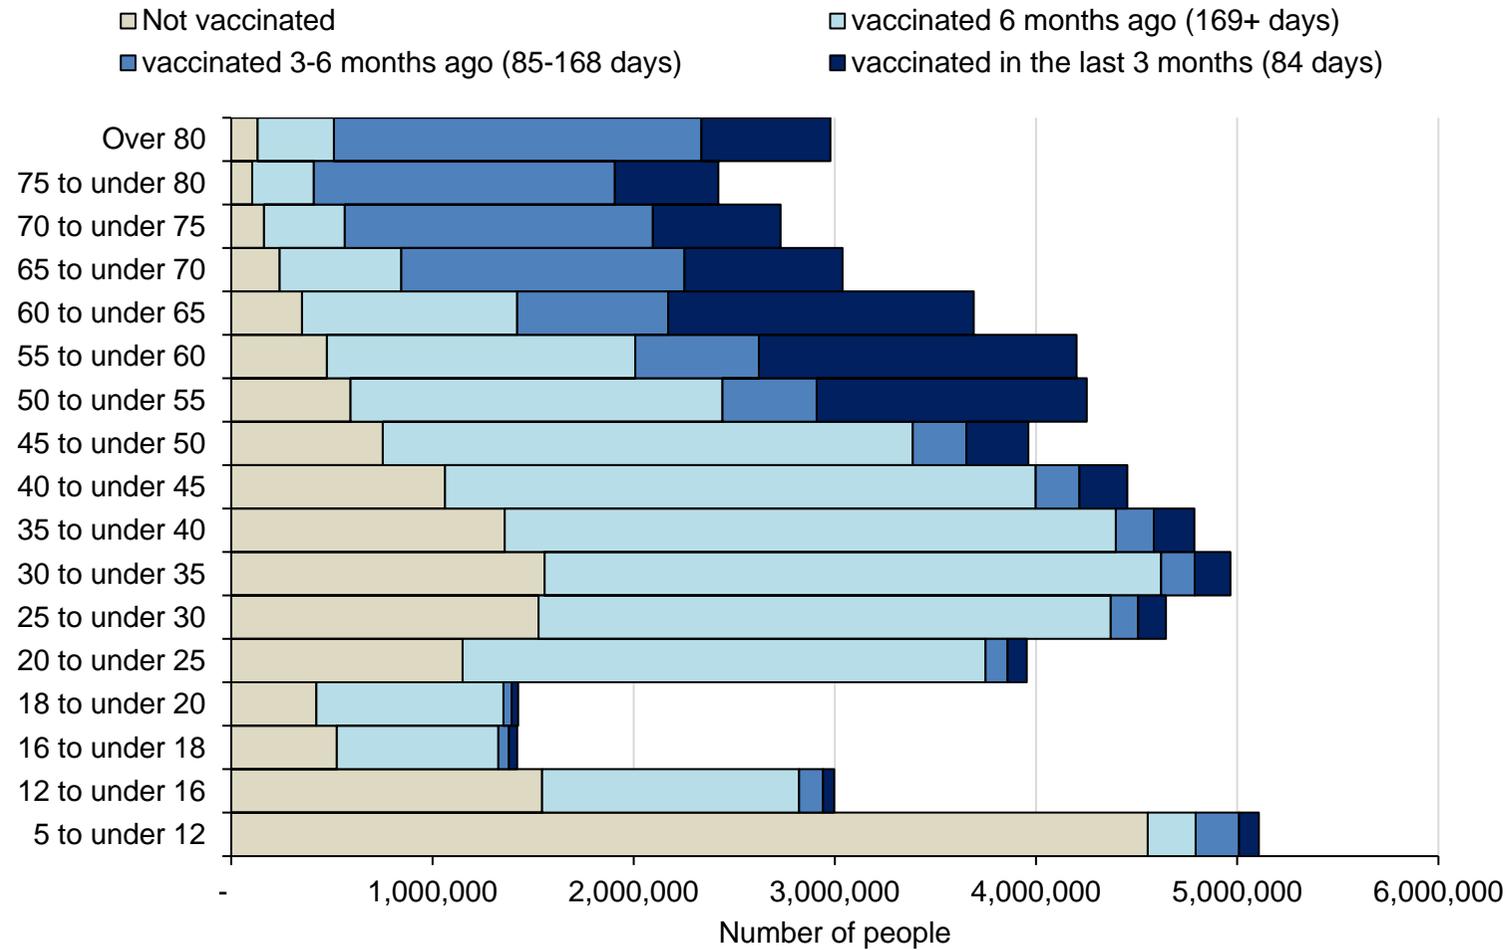

Figure 62: Provisional data on the proportion of people vaccinated with any dose of COVID-19 vaccine in the last 3 months, 3 to 6 months and vaccinated more than 6 months ago by ethnicity in those living and resident in England, aged 50 and over

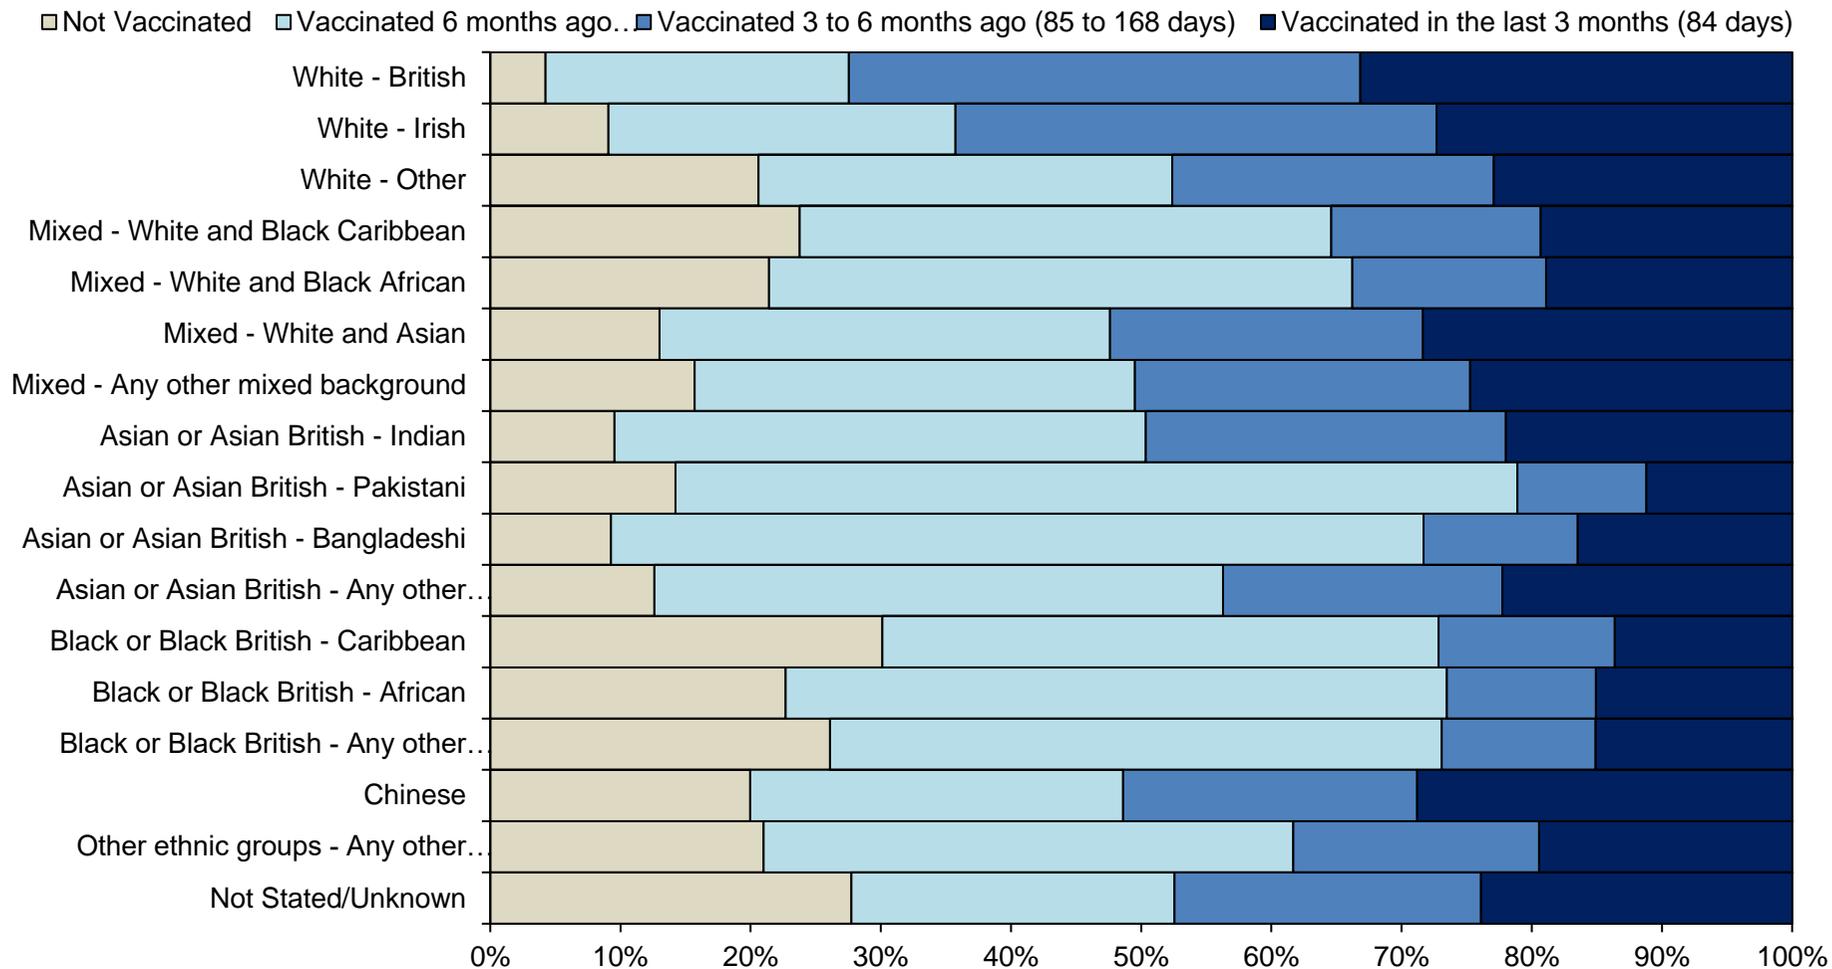

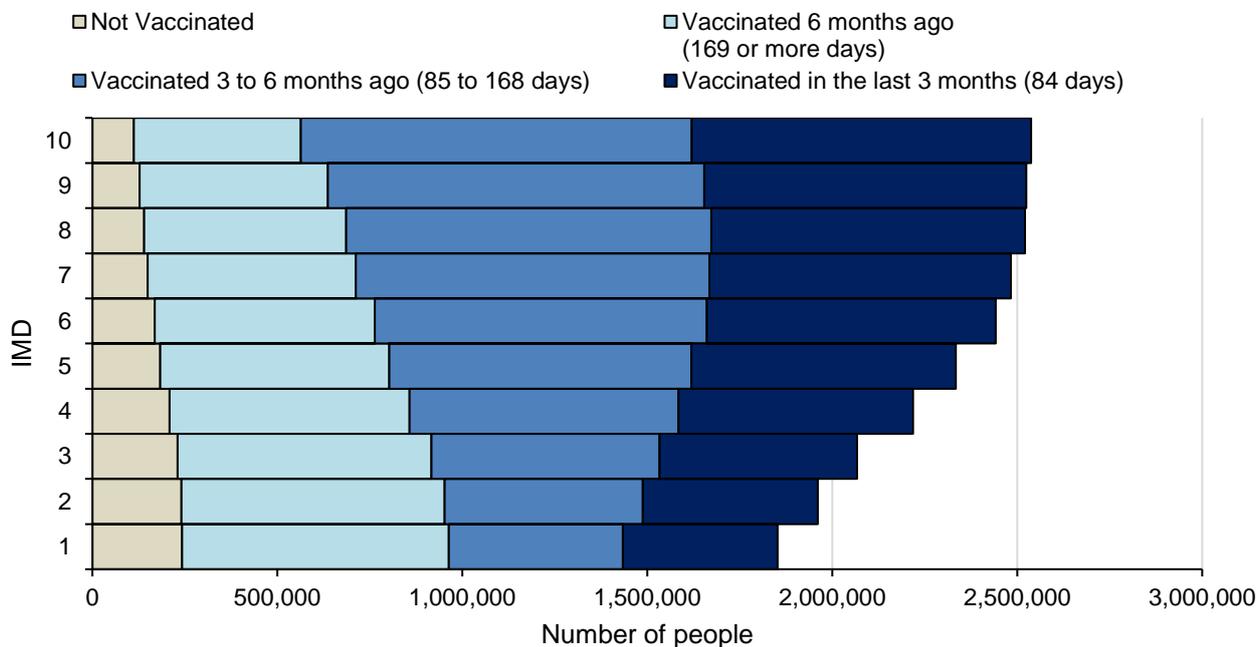

Figure 63: Provisional cumulative people vaccinated with any dose of COVID-19 vaccine in the last 3 months, 3 to 6 months and vaccinated more than 6 months ago by indices of multiple deprivation (IMD)* in those living and resident in England, aged 50 and over

*Decile 1 represents the most deprived 10% (or decile) of small areas in England and Decile 10 represents the least deprived 10% (or decile) of small areas in England.

For a regional breakdown of the ethnicity data, please see the data file that accompanies this report.

Immunosuppression

Provisional autumn booster vaccine uptake data in living and resident people identified as immunosuppressed in England to the end of week 1 (week ending 8 January 2023) was 68.1%, Table 10. Many people in this group have been vaccinated more recently and are still becoming eligible for their autumn booster. Table 11 is presented to provide an overview of how recently a person identified as immunosuppressed has been vaccinated either through the primary vaccination campaign or a subsequent booster campaign. This helps us understand the data in the context of vaccine waning across the whole COVID-19 programme and shows that most people identified as immunosuppressed have been recently vaccinated. This can be seen in Table 11, in which 69.7% of people identified as immunosuppressed are covered by a vaccine given in the last 6 months.

Table 10: Vaccine uptake in people identified as immunosuppressed in England with a booster of COVID-19 vaccine from the 1 September 2022 as part of the Autumn booster campaign*

Immuno-suppression	People in NIMS cohort who are living and resident in England	Vaccinated with an autumn booster since 1 September 2022*	Percentage vaccine uptake
England	489,443	333,215	68.1

*Autumn booster defined as any additional dose of vaccine after a 2 dose primary course provided there is an interval of at least 3 months, and it is given since the 1 September 2022

Table 11: People identified as immunosuppressed in England vaccinated with any dose of COVID-19 vaccine in the last 3 months, 3 to 6 months and vaccinated more than 6 months ago

People in NIMS Immuno-suppression cohort who are living and resident in England	Vaccinated in the last 3 months (84 days)		Vaccinated 3 to 6 months ago (85 to 168 days)		Vaccinated 6 months ago (169 or more days)	
	Numbers vaccinated	Percentage vaccinated	Numbers vaccinated	Percentage vaccinated	Numbers vaccinated	Percentage vaccinated
490,500	141,291	28.9	199,788	40.8	127,228	26.0

Detailed information on the NHS Digital characterisation of the immunosuppressed group can be found on the [NHS Digital website](#).

For COVID-19 data on the real-world effectiveness of the COVID-19 vaccines, and on COVID-19 vaccination in pregnancy, please see [the COVID-19 vaccine surveillance reports](#).

For COVID-19 management information on the number of COVID-19 vaccinations provided by the NHS in England, please see the [COVID-19 vaccinations](#) webpage.

For UK COVID-19 daily vaccination figures and definitions, please see the [Vaccinations' section of the UK COVID-19 dashboard](#)

The population coverage data representing the evergreen offer of doses 1, 2, and 3 has changed little in recent months and are no longer presented in both the UKHSA weekly flu and COVID-19 surveillance reports and in the UK COVID-19 Dashboard. Both the UKHSA weekly flu and COVID-19 surveillance reports and in the UK COVID-19 Dashboard now highlight data on the most recent vaccination campaign in those at higher risk from COVID-19 as immunity derived from vaccination declines over time. The overall vaccine uptake in the living and resident population for those with at least dose 1, 2 and 3 doses is still available within the backing tables for this section and in the dashboard APIs.

For a summary of the differences in denominators used to present administrative vaccine uptake by NHS England and vaccine coverage by UKHSA since the start of the COVID-19 programme, please see explainer [here](#). Please note that some administrative vaccine uptake data uses an ONS mid-year estimate as a denominator because not all devolved administrations have a national vaccine register. Please note that not everyone in the numerator will be in the denominator for administrative vaccine uptake where ONS mid-year estimates are used.

International update

Global COVID-19 update

For further information on the global COVID-19 situation please see the [World Health Organization \(WHO\) COVID-19 situation reports](#).

Global influenza update

Updated 23 December 2022 (based on data up to 11 December 2022) ([WHO website](#)).

Globally, influenza activity remained elevated due to activity in the northern hemisphere. Where subtyped, influenza A(H3N2) viruses predominated.

In the countries of North America, some indicators of influenza activity decreased while others were stable or continued to increase. Many indicators were above levels typically observed at this time of year and some were near or above levels observed at the peak of previous epidemics. Influenza A(H3N2) was the predominant virus detected.

In Europe, overall influenza activity continued to increase with influenza positivity from sentinel sites remaining above the epidemic threshold at the regional level. Influenza A viruses predominated with A(H3N2) viruses accounting for the majority of subtyped influenza A viruses from sentinel sites and influenza A(H1N1)pdm09 viruses predominant among non-sentinel samples in recent weeks.

In central Asia, influenza activity increased with relatively equal proportions of influenza A(H1N1)pdm09 and influenza B viruses reported. Influenza B viruses predominated in Kazakhstan and Uzbekistan while influenza A(H1N1)pdm09 predominated in Kyrgyzstan and Tajikistan.

In Northern Africa, influenza detections increased but remained low. Morocco reported mainly B/Victoria lineage virus detections. Tunisia reported increasing detections of mainly influenza A (H1N1)pdm09 as well as some influenza A(H3N2) and influenza B/Victoria lineage virus detections.

In Western Asia, influenza activity decreased overall with all seasonal influenza subtypes detected in similar proportions, though increased activity was reported in some countries.

In East Asia, influenza activity of predominantly influenza A(H3N2) remained low overall among reporting countries but with some increases reported in southern China and the Republic of Korea.

In the Caribbean and Central American countries, influenza activity of predominantly influenza A(H3N2) viruses decreased but remained elevated in Mexico.

In the tropical countries of South America, influenza detections were low, and A(H3N2) viruses predominated.

In tropical Africa, influenza activity remained low with detections of all seasonal influenza subtypes reported. An increased number of detections was reported from Eastern Africa.

In Southern Asia, influenza activity continued to decrease to low levels, mainly due to decreased activity reported in Iran. Influenza A(H1N1)pdm09 was the most frequently detected subtype in the subregion.

In South-East Asia, detections of predominantly influenza B increased and remained elevated.

In the temperate zones of the southern hemisphere, influenza activity decreased in Argentina and Chile and remained low elsewhere.

The WHO GISRS laboratories tested more than 447,351 specimens during that time period. 81,619 were positive for influenza viruses, of which 79,209 (97%) were typed as influenza A and 2,410 (3%) as influenza B. Of the sub-typed influenza A viruses, 4,722 (28.6%) were influenza A(H1N1)pdm09 and 11,791 (71.4%) were influenza A(H3N2). Of the 370 characterized B viruses, all belonged to the B-Victoria lineage.

Influenza in Europe

Updated for data for week 52 2022 ([Joint ECDC-WHO Europe Influenza weekly update](#)).

The percentage of sentinel primary care specimens from patients presenting with ILI or ARI symptoms that tested positive for an influenza virus remained above the epidemic threshold (10%) and slightly decreased to 34% from 37% in the previous week most probably due to the impact of the festive period with lower testing and reporting.

For week 52 2022, of 32 countries and areas reporting on intensity of influenza activity, 11 reported low-intensity (across the Region), 5 reported medium-intensity (Belgium, France, Israel, Kosovo), 11 reported high-intensity (across the Region) and 5 reported very high-intensity (Austria, Finland, Latvia, Luxembourg and Russian Federation).

Of 31 countries and areas reporting on geographic spread of influenza viruses, 1 reported no activity (Azerbaijan), 1 reported sporadic spread (United Kingdom (Northern Ireland)), 1 reported local spread (Malta), 6 reported regional spread (Bulgaria, Hungary, North Macedonia, Romania, Serbia and Kosovo) and 22 reported widespread activity (across the Region)

For week 52 2022, 821 (34%) of 2,384 sentinel specimens tested positive for an influenza virus; 92% were type A and 8% were type B. Of 418 subtyped A viruses, 67% were A(H3) and 33% A(H1)pdm09. All 15 type B viruses ascribed to a lineage were B/Victoria.

Of 27 countries and areas across the Region that each tested at least 10 sentinel specimens in week 52 2022, 25 reported positivity at or above 10% (median 44%; range 10% - 83%): Republic of Moldova (83%), Sweden (80%), Lithuania (75%), Slovakia (73%), Slovenia (64%), Poland (62%), the Netherlands (58%), Estonia (54%), Russian Federation (47%), Ukraine (46%), France (45%), Luxembourg (44%), Norway (44%), Germany (43%), Serbia (37%), Armenia (33%), Switzerland (33%), Uzbekistan (33%), Kyrgyzstan (29%), Tajikistan (26%), United Kingdom (Northern Ireland) (24%), Spain (21%), Portugal (20%), Italy (18%) and Kosovo (10%).

For the season to date, 9,603 (20%) of 47,319 sentinel specimens tested positive for an influenza virus. More influenza type A (n=8,957, 93%) than type B (n=646, 7%) viruses have been detected. Of 6,992 subtyped A viruses, 5,582 (80%) were A(H3) and 1,410 (20%) were A(H1)pdm09. All 200 influenza type B viruses ascribed to a lineage were B/Victoria (69% of type B viruses were reported without a lineage).

For week 52 2022, 20,884 of 84,164 specimens from non-sentinel sources (such as hospitals, schools, primary care facilities not involved in sentinel surveillance, or nursing

homes and other institutions) tested positive for an influenza virus; 19,523 (94%) were type A and 1,361 (6%) were type B. Of 4,540 subtyped A viruses, 3,191 (70%) were A(H1)pdm09 and 1,349 (30%) A(H3). All 19 type B viruses ascribed to a lineage were B/Victoria.

For the season to date, more influenza type A (n=93,895, 94%) than type B (n=5,823, 6%) viruses have been detected. Of 30,782 subtyped A viruses, 17,056 (55%) were A(H1)pdm09 and 13,726 (45%) were A(H3). All 507 influenza type B viruses ascribed to a lineage were B/Victoria (91% of type B viruses were reported without a lineage).

Influenza in North America

For further information on influenza in the United States of America please see the [Centre for Disease Control weekly influenza surveillance report](#). For further information on influenza in Canada please see the [Public Health Agency weekly influenza report](#).

Influenza in Australia

For further information on influenza in Australia please see the [Australian Influenza Surveillance Report and Activity Updates](#).

Other respiratory viruses

Avian influenza and other zoonotic influenza

[Latest WHO update on 11 November 2022](#)

From 6 October to 11 November 2022, one human case of infection with an avian influenza A(H5) virus, three human case of infection with an avian influenza A(H5N1) viruses, one human case of infection with an influenza A(H9N2) virus, one human case of infection with an influenza A(H1N1) variant virus, and one human case with an influenza A(H1N2) variant virus were reported officially. Additionally, two human cases of infection with influenza A(H3N2) variant viruses were detected.

The overall public health risk from currently known influenza viruses at the human-animal interface has not changed, and the likelihood of sustained human-to-human transmission of these viruses remains low. Human infections with viruses of animal origin are expected at the human-animal interface wherever these viruses circulate in animals.

Middle East respiratory syndrome coronavirus (MERS-CoV)

From April 2012 to October 2022, a total of 2,600 laboratory-confirmed cases of MERS-CoV and 935 associated deaths were reported globally to [WHO](#) under the International Health Regulations (IHR 2005).

Between 29 December 2021 and 31 October 2022, four laboratory-confirmed cases of MERS-CoV were reported to WHO by the Ministry of Health of the Kingdom of Saudi Arabia. No deaths were reported ([WHO website](#)).

On 28 April 2022, the National IHR Focal point of Oman notified WHO of one case of MERS-CoV in Oman ([WHO website](#)).

Between 22 March and 3 April 2022, the National IHR Focal Point of Qatar reported 2 laboratory-confirmed cases of Middle East respiratory syndrome coronavirus (MERS-CoV) infection to the WHO ([WHO website](#)).

A total of 5 cases of Middle East respiratory syndrome coronavirus, MERS-CoV, (3 imported and 2 linked cases) have been confirmed in the UK through ongoing surveillance since September 2012.

[Further information on management and guidance of possible cases](#) is available online. The latest [ECDC MERS-CoV risk assessment](#) highlights that risk of widespread transmission of MERS-CoV remains very low.
