Executive summary

These practical guidelines from the UK Health Security Agency (UKHSA) Advisory Committee on Malaria Prevention (ACMP) are updated and reissued annually. They are intended for use by healthcare workers who advise UK-based travellers to malaria-endemic areas but may also be of use to prospective travellers who wish to read about the options themselves.

We recommend health professionals stick to using one resource for country-specific malaria recommendations to optimise consistency of advice. Whilst we recognise that other sources of advice are available, healthcare professionals working in England, Wales or Northern Ireland are advised to use the ACMP guidelines as their preferred source of guidance for malaria prevention.

The ACMP prophylaxis guidelines are intended for UK-based travellers and may not be appropriate for use by those residing in endemic areas.

Malaria prevention advice involves a combination of preventive measures (the ABCD of malaria prevention) including:

- Awareness of risk
- Bite prevention
- Chemoprophylaxis
- Diagnose promptly and treat without delay

Recommendations for antimalarials should be appropriate for the destination and tailored to the individual, taking into account possible risks and benefits to the traveller. As part of an individual stringent risk assessment it is essential that a full clinical history is obtained, detailing current medication, significant health problems and any known drug allergies.

While the focus of these guidelines is on malaria prevention, it should be emphasised that malaria prevention is only one aspect of pre-travel advice. A comprehensive risk assessment-based package of travel health advice should be provided to the traveller. Further resources for health professionals are listed under Information resources.

Main changes in this update of the guidelines

The full effect of coronavirus (COVID-19) on malaria eradication in endemic areas has yet to be determined, but a significant impact is anticipated (1).

COVID-19 had a dramatic effect on travel patterns which inevitably reduced the number of malaria cases imported into the UK in 2020 and 2021.
Case numbers are now increasing and the MRL and the Hospital for Tropical Diseases have noted a worrying trend of increased severity and/or higher parasitaemias in cases of falciparum malaria that do present.

As the clinical features of malaria are non-specific, there is a significant risk that imported cases of malaria may be wrongly diagnosed as COVID-19, influenza, or another infectious illness, resulting in delayed access to treatment with severe or fatal consequences. Death in the UK due to misdiagnosis of imported falciparum malaria as COVID-19 has already occurred.

Therefore, as international travel recovers further, the need to ensure protection against malaria for all those potentially exposed and maintain awareness of malaria as a possible diagnosis in returned travellers is greater than ever.

ACMP will keep its advice for travellers to individual countries under review as the situation evolves. It may be that due to increased transmission, the risk of malaria acquisition increases for travellers to some areas, with the possibility of re-introduction of malaria to areas recently considered to have interrupted transmission.

In this edition of the Guidelines, the section on insect bite avoidance has been further revised to emphasize the increasing importance of these measures in protecting against the acquisition of malaria.

The full effect of COVID-19 on in-country malaria eradication programmes has yet to be determined, but there are concerns that hard-won gains may be lost. The World Health Organization (WHO) World Malaria Report 2020 (2) indicates that many countries have reported moderate levels of disruptions.

These guidelines are available on the UKHSA website ‘Malaria: guidance, data and analysis’. This site should be checked regularly for subsequent updates and practitioners should ensure that they always use the latest version as recommendations may change.

Authorship

This guidance was written on behalf of the UKHSA ACMP by Professor Peter Chiodini, Dr Dipti Patel, Professor Larry Goodyer and Professor Hilary Ranson.

Acknowledgements

We are grateful to Professor James Logan and Dr Alex Kew for giving expert advice on mosquito bite avoidance measures.
We thank the ACMP Secretariat for continued support; Marie Blaze and Valerie Smith (UKHSA Malaria Reference Laboratory) for advice on country tables; Sanchayan Kanagarajah, Lynda Bramham; Terence Corrigan; Mary Gawthrop; and Anisha Desai for designing maps.

PLC is very grateful to Mrs Jane Chiodini MBE for her understanding over weekends lost to writing these guidelines

General issues

The ACMP prophylaxis guidelines are intended for UK-based visitors to malaria endemic areas and may not be appropriate for use by those residing in endemic areas.

We recommend health professionals stick to using one resource for country specific malaria recommendations to optimise consistency of advice. Whilst we recognise that other sources of advice are available, healthcare professionals working in England, Wales or Northern Ireland are advised to use the ACMP guidelines as their preferred source of guidance for malaria prevention. They are also available on the NaTHNaC website. Separate guidance is available in Scotland for health professionals, produced by the Scottish Malaria Advisory group – see the NHS Travax website.

Whilst these guidelines deal with malaria, malaria prevention is only one aspect of pre-travel advice. An overall risk assessment-based package of travel health advice should be provided to the traveller. Guidance on general travel risk assessment can be obtained from NaTHNaC, and from TRAVAX for those working in Scotland (see Information resources).

For doctors and nurses providing travel services in England who are regulated by the Care Quality Commission (CQC), the CQC website confirms that the provision of travel health services includes pre-travel risk assessments and travel health advice including malaria prevention.

In these guidelines, which have been specifically developed for travellers from the UK, there are a small number of instances where the advice given differs from that in guidelines from other countries or the World Health Organization. This is because travellers from the UK do not usually visit all possible localities of malaria-endemic countries and may not visit the same localities as travellers from other countries. Many travellers from the UK who enter malaria-endemic countries are visiting friends and relatives in localities from which people tend to migrate to the UK. They do not therefore suffer the same patterns of malaria exposure as permanent residents or tourists or those visiting for other reasons.

How to give the advice

Emphasise to the traveller the ABCD of malaria prevention:

- Awareness of risk
- Bite prevention
- Chemoprophylaxis
- Diagnose promptly and treat without delay
Emphasise that while no regimen is 100% effective, the combination of preventive measures advised will give significant protection against the potentially severe consequences of malaria acquisition.

Make use of visual aids, especially malaria distribution maps, and show examples of the preventive measures advised, such as aids to bite prevention.

Based on individual risk assessment, discuss the choices of chemoprophylaxis regimens and their individual advantages and disadvantages, including cost.

Provide the traveller with written information on malaria and its prevention. UKHSA has information leaflets on mosquito bite avoidance and travelling abroad to visit friends and relatives (see Information resources) in English, Arabic, Bengali, French, Gujarati, Hausa, Igbo, Punjabi, Spanish, Swahili, Yoruba, Urdu, Xhosa, and in BSL, large print, braille, and Easy Read. These may be downloaded, photocopied and distributed free of charge. English versions are also available to order.

Medical history of the traveller

As part of an individual stringent risk assessment it is essential that a full clinical history is obtained, detailing current medication including those drugs prescribed by hospitals which may not appear on GPs’ drug lists for repeat prescriptions, significant health problems and any known drug allergies.

Safe and effective malaria prevention requires a sound knowledge of the medical history of the traveller. When their patients seek pre-travel advice in primary care, this information will be available from their own practice records but in the case of specialist travel clinics, malaria prevention advice may be sought at the first attendance. The General Medical Council (3) states:

"If you are not the patient's general practitioner and you accept a patient for treatment without a referral from the patient's practitioner, then you must: (a) explain to the patient the importance and benefits of keeping their general practitioner informed and (b) inform the patient's general practitioner unless the patient objects."

ACMP suggests that in all scenarios where advice is given, a written record of the malaria prevention measures advised is given to the traveller so that they may pass it on to their GP. A template for risk assessment and summary of advice given is provided at Appendix 2, which can be used for gathering the information required for risk assessment when advising on malaria prevention. It may be adapted for the particular circumstances of individual clinics.
Awareness of risk

Malaria facts

Malaria is a serious febrile illness due to infection of red blood cells with a parasite called Plasmodium. It is transmitted by mosquitoes.

Five species of Plasmodium (P) regularly infect humans (see Table 1 below).

Mixed infections with more than one species of malaria parasite are not commonly reported (14 in the UK in 2019).

In recent years, the incidence of *P. vivax* in UK travellers has dropped, but in regions where it is a problem, the risk of acquiring vivax malaria is year round (4).

Table 1. *Plasmodium* species that infect humans

Life cycle

An infected mosquito inoculates 10 to 15 sporozoites when it bites. Each sporozoite introduced into a human that successfully enters a liver cell develops in 5 to 7 days (*P. falciparum*) into a schizont containing approximately 30,000 offspring (merozoites) which are released into the

¹ This is the last set of pre-pandemic cases and gives a more realistic pattern of case load and case mix against which preventive measures need to be directed. The annual UK malaria figures for the preceding January to December are released annually and can be found at Malaria: guidance, data and analysis.
bloodstream when the schizont ruptures. Each merozoite has the potential to infect a red blood cell. Once inside the red cell, the malaria parasite grows and divides over 24 hours (P. knowlesi), 48 hours (P. falciparum, vivax or ovale), or 72 hours (P. malariae) to form between 8 and 32 parasites, whereupon the red cell bursts to release them to infect new red cells. These cycles in the red cells continue, increasing the numbers of parasites in the infected person and leading to clinical illness. Some parasites in the red cells do not divide but form sexual stages (gametocytes) which mate if taken up by a biting female mosquito and thus complete the malaria life cycle. Figure 1 shows the points in the life cycle at which antimalarial preventive measures are targeted.

**Figure 1. The malaria life cycle**

This figure shows the life cycle described above in pictorial form, to indicate the points at which malaria preventative measures act. Bite prevention acts at the very start of the life cycle to prevent bites from infected mosquitoes; causal prophylaxis acts on the parasite in the liver suppressive prophylaxis acts on parasites in the red blood cells.
The malarial illness

Malaria can neither be confirmed nor excluded by clinical features alone. The common symptoms and signs are shown in Table 2. There may be no physical signs apart from fever, but it must be noted that even the absence of fever itself does not exclude the diagnosis in an ill patient. There is a risk of misdiagnosing malaria as influenza or other infectious illness: viral hepatitis (if jaundice is present), gastroenteritis (if diarrhoea is evident) or lower respiratory tract infection (cough can be a non-specific symptom).

Table 2. Clinical symptoms and signs of malaria (from the ACMP malaria treatment guidelines)

Non-specific symptoms of malaria:

- fever, sweats or chills
- malaise (vague discomfort)
- myalgia (muscle pain, tenderness) headache
- diarrhoea
- cough

Major features of severe or complicated falciparum malaria in adults:

- impaired consciousness or seizures
- renal impairment (oliguria < 0.4ml/kg bodyweight per hour or creatinine
  >265μmol/l) Acidosis (pH <7.3)
- hypoglycaemia (<2.2mmol/l)
- pulmonary oedema or acute respiratory distress syndrome (ARDS) haemoglobin ≤8g/dL
- spontaneous bleeding or disseminated intravascular coagulation shock (algid malaria)
- haemoglobinuria (without G6PD deficiency)

Major features of severe or complicated malaria in children:

- impaired consciousness or seizures, respiratory distress or acidosis (pH <7.3)
  hypoglycaemia
- severe anaemia
- prostration (inability to sit or stand) parasitaemia >2% red blood cells parasitised
Where malaria is found

Figure 2 shows the countries with indigenous cases of malaria as at 2019 courtesy of WHO (5). It is for illustration only and should not be used to advise individual travellers on chemoprophylaxis. Changes in malaria prevalence as a result of interrupted control efforts due to the COVID-19 pandemic may result in indigenous cases occurring in areas previously thought to be malaria free. Choice of preventive measures should be based on the information stated in Table 7, supported by the text of these guidelines.

In-country maps of prophylactic advice linked to malaria distribution are available for selected countries in these guidelines for use when advising individual travellers and can be printed for them. The likelihood of malaria transmission may vary considerably within one country.

Practitioners should be aware of the recognition of *P. knowlesi* as the fifth malaria parasite of humans. It is a parasite of macaques and a zoonosis in humans in the Asia-Pacific region. As its asexual cycle takes only 24 hours, it is possible for its parasitaemia to rise more rapidly than with the other malaria species. A further danger is its close morphological resemblance to *P. malariae* which is a much less severe infection.
Guidelines for malaria prevention in travellers from the UK: 2022

Therefore, *P. knowlesi* should be urgently considered in any patient with malaria from the Asia-Pacific region with what appears to be *P. malariae*. Whilst *P. knowlesi* is a zoonosis and thus not amenable to control in the same way as those parasites which infect humans alone, prevention of human infection still relies on bite prevention, awareness of risk and chemoprophylaxis. *P. knowlesi* is sensitive to chloroquine.

**Level of risk of exposure to malaria and what affects it**

Exposure of individual travellers to malaria is influenced by the number of infectious bites received. Factors affecting the number of infectious bites received are given below.

**Temperature, altitude and season**

The optimum conditions for malaria transmission are high humidity and an ambient temperature in the range 20 to 30°C (6).

Malaria transmission does not usually occur in regions with temperatures below the 16°C isotherm (line on a weather map joining all the places that have the same average temperature over a given time).

Parasite maturation in the mosquito usually cannot take place at altitudes greater than 2,000 metres. However, it has been reported at altitudes up to 2,500 metres in some countries.

Seasonal rainfall increases mosquito breeding and in some areas malaria is highly seasonal.

**Rural versus urban location**

Malaria incidence is generally higher in rural than in urban areas, especially in Africa where the intensity of transmission is on average about 8 times higher in villages than towns (7) but as Africa becomes increasingly urbanised, the risk of contracting malaria in African or other cities of malaria-endemic areas must not be discounted (8).

**Type of accommodation**

An impregnated bed net should be used unless the accommodation is fitted with functioning air-conditioning and windows and doors which are sufficiently well sealed to prevent mosquito entry.

Backpackers staying in cheap accommodation have a higher risk of being bitten compared to tourists staying in air-conditioned hotels.
The traveller should embark on their journey equipped with mosquito protection measures appropriate to their particular circumstances.

**Patterns of activity**

Being outdoors between dusk and dawn when Anopheles mosquitoes bite increases the risk.

**Length of stay**

The longer the stay, the higher the risk of contracting malaria.

**Distribution of drug-resistant malaria**

Chloroquine-resistant falciparum malaria is now widespread (effectively universal). *P. falciparum* has also developed resistance to a variety of other agents in certain areas. Further comment on the extent and severity of drug resistance is given in the country table in Chemoprophylaxis.

There is currently no recorded drug resistance to *P. ovale* and only one report of drug-resistant *P. malariae* (to chloroquine) (9).

Chloroquine-resistant *P. vivax* is found in the Indonesian archipelago, the Malay Peninsula, including Myanmar, and eastward to Southern Vietnam and may have spread further (10).

*P. vivax* with reduced susceptibility to primaquine is found in South-East Asia and Oceania and higher doses of primaquine are required to achieve radical cure of this parasite from those areas. A higher dose may also be required for *P. vivax* from India, Pakistan, Afghanistan and South America (10).
Bite prevention

Note: Effective bite prevention should be the first line of defence against malarial infection.

For some destinations, ACMP advises awareness of risk and bite prevention for malaria prevention and does not recommend chemoprophylaxis. Practitioners are strongly advised that where chemoprophylaxis is also recommended, the benefits from using bite prevention measures, not only against malaria, but also in protecting against infection with other vector-borne diseases are emphasised to travellers.

When female Anopheles mosquitoes bite

Biting time varies between species, so travellers should assume they are at risk of being bitten mainly, but not only, from dusk to dawn inclusive. The biting of several major malaria vectors in Africa peaks at and just after midnight so protection in bed is especially important. However, in many parts of South America and South-East Asia, the greatest risk from being bitten by malaria vectors is in the evening, before the population retires indoors. Furthermore, as other species of mosquito – for example, those which transmit yellow fever, dengue fever and other arboviral infections, bite during the daytime – it is important to maintain bite precautions during daylight hours, both indoors and outdoors.

Measures to prevent mosquito bites

Repellents

As malaria prevention in travellers becomes reliant on bite avoidance and awareness of risk in more and more destinations, much greater attention to the correct use of insect repellents is required.

Debboun and Goodyer (11) have highlighted the fact that users decide whether or not to use an arthropod repellent for personal protection, what kind to use, and how much to apply. Therefore, the travel health advisor should emphasize the importance of adhering to the ACMP recommendations for their use, to achieve optimal protection, especially as repellents have an excellent safety profile.

In some circumstances, ACMP advice may differ from that in repellent manufacturers’ product information. When this occurs, the recommendations in these guidelines (which are based on current expert advice from the ACMP) should be followed.

ACMP recommends a 50% DEET-based insect repellent as a first choice. If DEET is not tolerated (or is not available), an alternative preparation (see below) should be used.
Consult the instructions for use for individual products. Reapplication should be made when necessary, to ensure that mosquitoes are not biting, bearing in mind safe limits for the product concerned.

The 4 active ingredients described below are all incorporated into repellent formulations available on the UK market. If a product does not contain one of these active ingredients, it should not be used. They have excellent mosquito repellent properties, though DEET is supported by the strongest evidence base and its extensive use worldwide over the last 50 years.

In the field many factors will affect the perceived longevity of a repellent before reapplication is required including; the mosquito biting pressure, sweat and run off of the repellent, species of mosquito and ‘attractants’ produced by the individual. One of the most important factors, and one that can be controlled by the user, is the amount of repellent applied to exposed skin. In general, the higher the dose of active ingredient on the skin the longer the protection achieved. However, it has been demonstrated (13) that travellers will tend to apply almost half of the amount at which a product has been tested according to current protocols. Therefore, the stated longevity on manufacturers’ packaging may not be achieved in the field and more frequent application will be required.

The general recommendations of the ACMP concerning repellent use are:

1. Use a 50% DEET-based repellent and if not tolerated or preferred by the traveller, the highest strength available of either an icaridin or eucalyptus citriodora oil, hydrated, cyclized or 3-ethylaminopropionate-containing repellent. Long-acting formulations may increase longevity of the active ingredient but further evidence is required to demonstrate their advantages.
2. As a guide, users should reapply repellents when the mosquitoes begin to land, to ensure that they do not bite.
3. Some volatile oils from plant products, including citronella, do have repellent properties but they are usually short lasting. There is insufficient data to support the use of blends of such oils as reliable repellents.

DEET
DEET (N,N-diethyl-m-toluamide) has been in use as an insect repellent for more than 50 years and is reportedly used worldwide by approximately 200 million people each year (14). It is available in a variety of concentrations and in various preparations including sprays and a slow release preparation. A variety of studies has concluded that there is a low risk of adverse effects when DEET is applied according to product directions (14).

ACMP recommends using a 50% DEET-based insect repellent if available. There is no further increase in duration of protection beyond a concentration of 50% DEET (14).
Sweat-off time varies with activity. The interval between applications depends on this as well as the DEET formulation and concentration used.

**DEET and sunscreen**

Several studies have evaluated the impact of co-application of sunscreen and DEET. DEET (33%) has been shown to decrease the protection from SPF 15 sunscreen 15 but there is no evidence that sunscreen reduces the efficacy of DEET when used at concentrations above 33% (15, 16). Frequent (every 2 hours) reapplication of sunscreen over DEET applied at below 20% (17%), was found to reduce the mean repellency rate and also mean protection time (by about one hour) compared with DEET alone (16).

Stanczyk and colleagues (17) recommended advising travellers to: apply repellent first and be aware that repellent may wear off more quickly if reapplying only sunscreen on top or use a combined repellent and sunscreen product.

Note: In contrast to reference 17, ACMP’s view is that as repellent activity will reduce more quickly than that of a sunscreen if reapplying only sunscreen on top, repellent will therefore usually need to be reapplied on top of a sunscreen. When both sunscreen and DEET are required, DEET should be applied after the sunscreen. Thirty to 50 SPF sunscreen should be applied to compensate for DEET-induced reduction in SPF. Sunscreen is not required from dusk to dawn.

**DEET and infants**

DEET is not recommended for infants below the age of 2 months. If a particular DEET manufacturer’s product information recommends a higher age cut off for use in children, the ACMP guidance should be followed.

**DEET and pregnancy**

Use of 20% DEET in the second and third trimesters of pregnancy was not associated with adverse effects on infants from those pregnancies followed for up to 12 months after birth (18). Given the seriousness of malaria in pregnancy, ACMP recommends the use of DEET at a concentration of up to 50% as part of the malaria prevention regimen for pregnant women, including those in the first trimester. DEET may be used at a concentration of up to 50% in breast feeding and for infants and children aged over 2 months.

ACMP advice on use of DEET for protection from mosquito bites is that:

- DEET is suitable for all individuals over the age of 2 months (unless allergic), and furthermore, the United States Environmental Protection Agency states that DEET is approved for use on children with no age restriction (accessed 23 July 2022)
- there is no current evidence that any group (including pregnant women and small children) is at increased risk from using 50% DEET. The US Environmental Protection Agency (EPA) examined data on seizures potentially related to DEET
exposure and concluded that observed incidence of recognized seizures is about one per 100 million users (19).

- DEET applications can damage some plastic watch straps, watch covers and plastic jewellery; these items should not be allowed to come into contact with DEET
- the user should ensure that repellents are not ingested or inhaled and do not come into contact with their eyes or mouth
- repellents should be used only on exposed areas of skin

Eucalyptus citriodora oil, hydrated, cyclized

Eucalyptus citriodora oil, hydrated, cyclized was previously known as p-menthane 3,8 diol or PMD (see the European Chemicals Agency June 2016 minutes). Eucalyptus citriodora oil, hydrated, cyclized is a repellent that occurs naturally in the lemon eucalyptus plant and has structural similarities with the chemical menthol. This natural product can now be obtained synthetically.

Plant-based repellents have become more popular in recent years (Debboun and Goodyer ref). For those travellers preferring plant-based repellents, Eucalyptus citriodora oil, hydrated, cyclized is the only active ingredient recommended by ACMP.

Eucalyptus citriodora oil, hydrated, cyclized is also an effective repellent (20, 21, 22). 15% DEET slightly outperformed 15% Eucalyptus citriodora oil, hydrated, cyclized as a repellent against *Anopheles stephensi* under laboratory conditions (23) but Eucalyptus citriodora oil, hydrated, cyclized remains a very useful repellent. If Eucalyptus citriodora oil, hydrated, cyclized is chosen by the traveller, more frequent application would be required than if DEET were used.

Eucalyptus citriodora oil, hydrated, cyclized is well tolerated with low toxicity when used according to the manufacturers’ instructions. Accidental application to the eye can result in corneal damage, so the EPA concluded that product labels should clearly emphasize the hazard and first aid treatment for accidental eye exposure (24).

Icaridin (Picaridin)

Icaridin (KBR3023) (1piperidinecarboxylic acid, 2-(2hydroxyethyl)-,1-methyl-propylester) has repellent properties comparable to those of DEET (25, 26) with a comparable duration of protection (27, 28, 29) when both are used at 20%. Icaridin is available in various concentrations between 2% and 20% (30, 31). If a traveller elects to use icaridin for mosquito bite prevention, ACMP advises use of a 20% preparation.

Icaridin is well tolerated. Adverse events are uncommon and mild, with mostly cutaneous side effects (32) There have been some studies reporting fewer skin side effects when using icaridin versus DEET, albeit using lower concentrations of icaridin (33).
3-ethylaminopropionate
In some studies 3-ethylaminopropionate (IR3535) has shown a shorter duration of protection against mosquitoes than DEET when used at the same concentration (28, 34, 35) but is still a safe and effective repellent which has been in use for more than 25 years.

If IR3535 is chosen by the traveller, more frequent application may be required than if DEET were used.

Accidental application of IR3535 to the eye can result in moderate eye irritation (29) so appropriate warnings about avoiding accidental eye exposure and the need for first aid measures are required.

Oil of citronella
While oil of citronella-based products do have repellent properties, they provide short-lived protection (34) and are not recommended by ACMP. Citronella has been withdrawn in Europe.

Insecticides
Permethrin and other synthetic pyrethroids have a rapid knock-down effect on mosquitoes and are used to kill resting mosquitoes in a room.

Nets
Using multiple methods to prevent arthropod bites concurrently is more effective than using a single method, which underlies the use of insecticide-treated bed nets, which have become an important and cost-effective method of bite prevention globally (36).

All travellers to malaria-endemic areas should sleep under a mosquito net unless they are in a well screened room with mosquito netting on windows and doors into which mosquitoes cannot enter, or a room with functioning air conditioning into which mosquitoes cannot enter.

Insecticide-treated mosquito nets should be used. Protective efficacy against malaria for travellers has been estimated at 50% (37).

Mosquito bed nets must be free of tears, tucked in under the mattress and taut, not drooping. Insecticide (pyrethroid)-impregnated bed nets improve protection because they help to prevent (a) biting through the net on parts of the body touching the net, (b) mosquitoes surviving long enough near a net to find any tears in the net which may exist. (37).

Most of the nets now available are long-lasting impregnated nets (LLINs). In these products the pyrethroid is incorporated into the material of the net itself or bound to it with a resin (38). They have an expected useful life of at least 3 years. Impregnated nets other than LLINs will need to be re-impregnated every 6 to 12 months (depending on how frequently the net is washed) to remain effective (39). Follow the instructions for the product concerned.
Guidelines for malaria prevention in travellers from the UK: 2022

**Clothing**

Within the limits of practicality, cover up with long sleeves, long trousers and socks if out of doors after sunset, to minimise accessibility to skin for biting mosquitoes. There is no evidence that the colour of clothing is relevant to mosquitoes.

Clothing may be sprayed or impregnated with an insecticide, for example, permethrin (39) or purchased pre-treated to reduce biting through the clothing. This can provide a high level of bite prevention (40) and is recommended by ACMP.

As an alternative to insecticides, WHO states that any of the repellents considered safe for skin application may be used to treat clothing (36).

Cotton clothing (for example, socks) can be sprayed with DEET. DEET is useful as a clothing repellent but its duration on clothing is shortened due to its volatility (41). DEET preparations for use only on clothing are commercially available, but may ruin synthetic fabrics.

A repellent should still be applied to exposed skin even if the clothing has been treated.

**Room protection**

Room protection represents an important component of malaria prevention, but should never be relied upon on its own.

Air conditioning reduces the likelihood of mosquito bites because of substantial reduction in nighttime temperature and increased air flow. Ceiling fans reduce mosquito nuisance.

Doors, windows and other possible mosquito entry routes to sleeping accommodation should be screened with fine mesh netting which must be close-fitting and free from tears.

The room should be sprayed before dusk with a knockdown insecticide (usually a pyrethroid) to kill any mosquitoes which may have entered the accommodation during the day.

During the night, where electricity is available, use a proprietary heated liquid reservoir device containing insecticide or an electrically heated device to vaporise a ‘mat’ (tablet) containing a synthetic pyrethroid in the room.

Burning of a mosquito coil containing insecticide must not be undertaken indoors, but can be deployed outside to repel and kill mosquitoes (42).

**Fallacies**

**Herbal remedies**

The ACMP strongly advises against relying on any herbal remedies for the prevention of malaria. Herbal remedies have not been tested for their ability to prevent or treat malaria.
Guidelines for malaria prevention in travellers from the UK: 2022

Homoeopathy
The ACMP strongly advises against relying on any homoeopathic remedies for the prevention of malaria. There is no scientific proof that homoeopathic remedies are effective in either preventing or treating malaria. In addition, the Faculty of Homoeopathy does not promote the use of homoeopathic remedies for malaria prevention.

Buzzers
Electronic buzzers (emitting high frequency sound waves) are completely ineffective as mosquito repellents. Companies selling them have been prosecuted and fined under the UK Trades Descriptions Act and ACMP advice is that they should not be used. The use of apps available on mobile phones to prevent mosquitoes biting is also strongly discouraged by ACMP.

Vitamin B1
There is no evidence that vitamin B1 taken orally repels mosquitoes (41, 42).

Vitamin B12
There is no evidence that vitamin B12 taken orally has a repellent effect on mosquitoes.

Garlic
There is no evidence that garlic taken orally repels mosquitoes (43).

Savoury yeast extract spread
It is sometimes stated that Marmite® taken orally repels mosquitoes either by giving off a cutaneous odour repellent to mosquitoes or via its vitamin B1 content. There is no evidence that either assertion is true.

Tea tree oil
There is no evidence that tea tree oil is an effective mosquito repellent.

Bath oils and emollients
There is no evidence that proprietary bath oils provide effective protection against mosquito bites.

Alcohol
Alcoholic drinks do not protect against mosquito bites. Indeed, beer consumption is reported to increase human attractiveness to malaria mosquitoes (44).

Gin and tonic has no mosquito repellent properties and the amount of quinine in tonic water has no effect on malaria parasites.
Chemoprophylaxis

Recommendations for antimalarials should be appropriate for the destination and tailored to the individual, taking into account possible risks and benefits to the traveller. As part of an individual stringent risk assessment it is essential that a full clinical history is obtained, detailing current medication, significant health problems and any known drug allergies. For a suggested risk assessment template see Appendix 2.

Given the possibility of antimalarials purchased in the tropics being fake or sub-standard (45), travellers should obtain the medication required for their chemoprophylaxis from a reputable source in the UK before they travel. ACMP advises those purchasing antimalarial drugs over the internet to ensure that they are dealing with a bona fide supplier or website.

Principles

Causal prophylaxis

Causal prophylaxis is directed against the liver stage of the malaria parasite, which takes approximately 7 days to develop (see life cycle in Figure 1). Successful drug activity at this stage prevents the parasite from progressing to infect red blood cells.

Causal prophylactics need to be continued for approximately 7 days after infection (46), so ACMP recommends that they are continued for 7 days after leaving a malarious area (see Table 3).

It is important not to confuse liver-stage schizonts with hypnozoites. All 5 species of human malaria have liver-stage schizonts but only P. vivax and P. ovale have the hypnozoite stage, against which causal prophylaxis is not effective.

Suppressive prophylaxis

Suppressive prophylaxis is directed against the red blood cell stages of the malaria parasite. Therefore, to prevent infection, suppressive prophylactic drugs should be continued for 4 weeks after leaving a malarious area (47) (see drug regimens in Table 3).

Prophylaxis against hypnozoites

P. vivax and P. ovale have a dormant stage called the ‘hypnozoite’. The hypnozoite remains dormant for months and then ‘wakes up’ to develop into a liver schizont. The dormant hypnozoite explains why attacks of vivax or ovale malaria can occur long after the end of chemoprophylaxis. This is not due to drug failure, as none of the prophylactic drugs currently advised by ACMP acts against the hypnozoite stage of P. vivax or P. ovale.
Primaquine is active against hypnozoites (present only in *P. vivax* and *P. ovale*) and is used in the treatment of these forms of malaria. It also has causal prophylactic activity against the liver stage schizonts of all malaria parasites of humans (48).

Primaquine is occasionally used for terminal prophylaxis, also known as presumptive anti-relapse therapy (PART), to eradicate hypnozoites of *P. vivax* and *P. ovale*.

However, the routine use of primaquine for prophylaxis or terminal prophylaxis is not recommended by ACMP.

Primaquine is not licensed in the UK and practitioners considering the use of primaquine as a prophylactic agent should consult an expert centre (see Information resources).

Primaquine is an oxidant drug and can lead to significant haemolysis in G6PD-deficient individuals.

**The drugs**

The Summaries of Product Characteristics (SmPCs) for each antimalarial agent contain the full prescribing information. The British National Formulary (BNF) covers some of the major aspects of the full prescribing information. The SmPCs and the BNF should be consulted as required when recommending malaria chemoprophylaxis.

The BNF and BNFC are now available in one app.

This section on individual drugs is not as detailed as that provided for prescribers in the SmPCs and BNF. In the sections that follow, some of the ACMP’s recommendations may not follow the SmPCs. In that situation we recommend following the ACMP recommendations.

This section should be read in conjunction with the chapters:

- **Awareness of risk**, which provides information on drug resistance
- **Chemoprophylaxis**, which provide details of recommended dose regimens
- **Special groups** and **Special categories**, which provide additional information on the use of antimalarial agents in special groups, including those with medical conditions (for example, pregnant and breastfeeding women and individuals with renal impairment) and those in special categories (for example, children and the elderly).

Note: Anybody from the UK, including members of the public, can report any suspected side effects from malaria medicines via the Yellow Card Scheme on the Medicines and Healthcare products Regulatory Agency (MHRA) website. Attacks of malaria that occur in individuals prescribed malaria prophylaxis should also be reported via this system.
Keep all medicines out of the sight and reach of children.

The following drugs are not listed in order of preference.

**Chloroquine**

**Mode of action**
Chloroquine is concentrated in the malaria parasite lysosome and is thought to act by interfering with malaria pigment formation, causing generation of a ferriprotoporphyrin IX-chloroquine complex which is highly toxic to the parasite.

**Efficacy**
Chloroquine-resistant falciparum malaria is now reported from all WHO regions except Central America north of the Panama Canal and the Island of Hispaniola (Haiti and the Dominican Republic). It remains effective against most *P. vivax*, all *P. ovale*, *P. knowlesi* and virtually all *P. malariae*.

**Formulations and method of administration**
Tablets contain 155mg chloroquine base; syrup contains chloroquine base 50mg/5 ml. To be taken orally with food. Antacids (aluminium, calcium and magnesium salts) and adsorbents (for example, kaolin) may reduce the absorption of chloroquine, so they should be taken at least 4 hours apart.

**Prophylactic regimen**
Adult dose 310mg (2 tablets) weekly, starting one week before entering a malarious area, continuing throughout the time in the area and for 4 weeks after leaving the area.

**Contraindications**
Allergy to chloroquine or to any other ingredients of the formulation (tablet or syrup).
Concomitant use with amiodarone

**Cautions**
Chloroquine should not be used in those with a history of epilepsy. The risk of epilepsy is higher in first degree relatives of those in whom this condition has been diagnosed so it should be considered as part of risk assessment. Epilepsy in a first-degree relative may not contraindicate the use of an antimalarial but may influence the choice of drug.

Chloroquine may exacerbate psoriasis and myasthenia gravis. Severe hypoglycaemia has occurred in diabetics and non-diabetics.

In long-term use, eye examinations every 6 to 12 months should be considered after 6 years' prophylactic usage, though the risk of retinopathy developing on prophylactic dosage is considered to be very low (49). See also long-term traveller section in Special categories.

Chloroquine is highly toxic in overdose and children are particularly susceptible.
Interactions
This section includes key interactions, but does not include all possible interactions. Practitioners should also consult the BNF and SmPC before prescribing.

Drugs: Use with amiodarone is contraindicated (increased risk of ventricular arrhythmias)

Other interactions include: ciclosporin (increased risk of ciclosporin toxicity); digoxin (possibly increases plasma concentration of digoxin); mefloquine (increased risk of convulsions); moxifloxacin (increased risk of ventricular arrhythmias).

Vaccines: Chloroquine may suppress the antibody response to pre-exposure intradermal human diploid cell rabies vaccine. This interaction is not seen when rabies vaccine is given intramuscularly (the currently recommended mode of vaccination in the UK).

Side-effects
Frequently reported side effects are gastrointestinal disturbances and headache. Convulsions and severe skin reactions have been reported. Chloroquine may cause itching, especially in persons of African descent.

Hydroxychloroquine
Hydroxychloroquine is usually used for the treatment of rheumatic diseases, in doses greater than those needed for malaria prevention. Individuals already taking hydroxychloroquine and for whom chloroquine would be an appropriate malaria chemoprophylactic agent, can remain on hydroxychloroquine and do not need to transfer to chloroquine. If doubt exists, seek expert advice.

Proguanil
Mode of action
Proguanil is converted to an active metabolite cycloguanil which inhibits the enzyme dihydrofolate reductase and interferes with the synthesis of folic acid. It acts as a suppressive and also as a causal prophylactic. Proguanil itself has a second mode of action, mediated by the parent drug rather than its metabolite, which produces synergy with atovaquone (see atovaquone plus proguanil).

Efficacy
There are very few regions in the world where the local P. falciparum strains are fully sensitive to proguanil.

Formulation and method of administration
100mg tablets. To be taken orally with food. Antacids (aluminium, calcium and magnesium salts) and adsorbents (for example, kaolin) may reduce the absorption of proguanil, so they should be taken at least 4 hours apart.
Prophylactic regimen
Adult dose 200mg daily, starting one week before entering a malarious area, continuing throughout the time in the area and for 4 weeks after leaving the area.

Contraindications
Allergy to proguanil or to any ingredient of the tablets

Cautions
Renal impairment. Pregnancy (folic acid 5mg daily is required for the length of time that proguanil is taken in pregnancy and also by those taking proguanil who are seeking to become pregnant).

Interactions
This section includes key interactions, but does not include all possible interactions. Practitioners should also consult the BNF and SmPC before prescribing.

Drugs: May enhance the anticoagulant effect of warfarin. Antifolate effect is increased when given with pyrimethamine.

Vaccines
None reported.

Side-effects
Frequently reported are mild gastric intolerance and diarrhoea. Mouth ulcers and stomatitis occur occasionally, particularly when co-administered with chloroquine.

Chloroquine plus proguanil
For side effects, interactions, contraindications and methods of administration, please see individual agents.

Mefloquine
As with any antimalarial, stringent risk assessment is required before advising mefloquine use.

Mode of action
Mefloquine’s mode of action has not been determined but is thought to be unrelated to that of chloroquine and not to involve an anti-folate action. It acts as a suppressive prophylactic.

Efficacy
The protective efficacy of mefloquine is 90% or more (52, 53). At the present time, significant resistance of *P. falciparum* to mefloquine is a problem only in some areas of South-East Asia (54), but is reported sporadically from the Amazon basin.

Formulation and method of administration
250mg tablets. Taken orally, preferably after a meal and with plenty of liquid.
Guidelines for malaria prevention in travellers from the UK: 2022

**Prophylactic regimen**

Adult dose 250mg weekly, starting 2 to 3 weeks before entering a malarious area to assess tolerability, continuing throughout the time in the area and for 4 weeks after leaving the area.

**Contraindications**

1. Allergy to mefloquine or to any ingredient of the tablets.
2. Allergy to quinine or quinidine.
3. A current or previous history of depression, generalized anxiety disorder, psychosis, schizophrenia, suicide attempts, suicidal thoughts, self-endangering behaviour or any other psychiatric disorder, epilepsy or convulsions of any origin. The risk of epilepsy and serious mental health disorders is higher in first degree relatives of those in whom these conditions have been diagnosed so they should be considered as part of risk assessment. A condition in a first-degree relative may not contraindicate the use of an antimalarial but may influence the choice of drug. Please read in conjunction with the section **Epilepsy** in these guidelines.
4. A history of Blackwater fever.
5. Severe impairment of liver function.

Use with halofantrine. Also, halofantrine should not be given within 15 weeks after the last dose of mefloquine.

Use of a checklist should ensure that proper screening is undertaken prior to mefloquine administration and these contraindications are followed (55). See also the manufacturer’s SmPC, Patient information leaflet and risk materials.

**Cautions**

Pregnancy and breast-feeding (see Special groups (medical conditions)), cardiac conduction disorders. Not recommended in infants under 5kg.

The SmPC points out that during clinical trials, mefloquine was not administered for longer than one year and states that periodic checks on liver function and eye assessments should be performed if mefloquine is used for a prolonged period. Any person taking mefloquine presenting with a visual disorder should be referred to their treating physician as this may require stopping chemoprophylaxis.

In those who have suffered traumatic brain injury, the decision whether to advise mefloquine chemoprophylaxis should be made on an individual basis after a detailed risk assessment.

**Diving and mefloquine**

If the individual tolerates mefloquine prophylaxis, there is no evidence that they cannot physically perform underwater diving. However, mefloquine does lower the seizure threshold and its side effects could potentially be confused with decompression or narcosis events. It should also be noted that some sub-aqua centres do not permit those taking mefloquine to dive. Mefloquine might therefore be better avoided for those undertaking diving holidays but there is no contraindication to its use in occasional divers who have taken and tolerated the drug before, or those able to start taking it early to ensure that no adverse events occur.
Pilots
The UK Civil Aviation Authority advises that mefloquine should not be administered to pilots, although there is no evidence that mefloquine impairs function.

The Military
The ACMP recognises that malaria risk is different in military and civilian travellers. The Ministry of Defence has prepared guidelines for malaria prevention specific to military personnel. Civilian practitioners asked to provide malaria prevention advice for members of the Armed Forces should liaise with the Defence Medical Services via Defence Medical Services Public Health Unit at SG-DMed-Med-DPHU-GpMailbox@mod.gov.uk

Interactions
This section includes key interactions, but does not include all possible interactions. Practitioners should also consult the BNF and SmPC before prescribing.

Drugs: Use with halofantrine is contraindicated.

Mefloquine antagonises the anticonvulsant effect of antiepileptics and may enhance the effect of other drugs that reduce the epileptogenic threshold, increasing the risk of convulsions. Use of mefloquine with other drugs that affect cardiac conduction may enhance the risk of serious cardiac arrhythmias. Mefloquine is metabolised in the liver by CYP3A4. Caution if administered with drugs that inhibit this enzyme due to increased mefloquine levels (for example, itraconazole) (52). Drugs that induce metabolism of mefloquine may be expected to reduce mefloquine levels (for example, rifampicin).

Ritonavir levels are reduced by mefloquine due to decreased absorption, but the clinical significance of this interaction is unknown.

Side-effects
Attention has focused on neuropsychiatric problems and vestibular disorders with mefloquine prophylaxis. Those taking mefloquine are more likely to have abnormal dreams, insomnia, anxiety and depressed mood during travel than those who take atovaquone-proguanil or doxycycline (56).

Increased neuropsychiatric adverse events have been found, especially in women using mefloquine, when compared with those receiving doxycycline, or atovaquone plus proguanil, but not those taking chloroquine plus proguanil (57). Increase the risk of psychosis and anxiety reactions (52, 58). No association between mefloquine prescriptions and hospitalisation has been demonstrated (59). Dizziness, balance disorder, tinnitus and vertigo may occur. In a small number of patients, it has been reported that dizziness or vertigo and loss of balance may continue for months after discontinuing the drug.

In February 2018 the SmPC added insomnia to the list of psychiatric symptoms that must be regarded as prodromal for a more serious event. The updated list is insomnia, abnormal dreams and/or nightmares, acute anxiety, depression, restlessness or confusion. Overall, mefloquine
remains an important prophylactic agent which is tolerated by most travellers who take it (52, 56, 60).

**Doxycycline**

**Mode of action**
Doxycycline is lipophilic and acts intracellularly, binding to ribosomal mRNA and inhibiting protein synthesis. It acts as a suppressive prophylactic.

**Efficacy**
Doxycycline is of comparable prophylactic efficacy to mefloquine (61).

**Formulations and method of administration**
Capsules (50 or 100mg) or dispersible 100mg tablets.

The capsules and solution of dispersible tablets should be swallowed with plenty of fluid in either the resting or standing position and the recipient should not lie down for at least 1 hour after ingestion to reduce the likelihood of oesophageal irritation and ulceration. If gastric irritation occurs, it is recommended that doxycycline is taken with food or milk.

Studies indicate that the absorption of doxycycline is not notably influenced by simultaneous ingestion of food or milk.

The absorption of doxycycline may be impaired by concurrently administered antacids containing aluminium, calcium, magnesium or by oral zinc, iron salts or bismuth preparations. Intake of these substances should be separated from dosing with doxycycline as far as possible.

**Prophylactic regimen**
Dose 100mg daily, starting 1 to 2 days before entering a malarious area, continuing throughout the time in the area and for 4 weeks after leaving the area.

**Contraindications**
Allergy to tetracyclines or to any ingredients of the capsules or dispersible tablets. Children under 12 years of age.

Use during pregnancy is contraindicated in the SmPC.

The UK National Teratology Information Service states that doxycycline is best avoided for antimalarial prophylaxis during pregnancy. However, if required before 15 weeks’ gestation it should not be withheld if other options are unsuitable (62). The course of doxycycline, including the 4 weeks after travel, must be completed before 15 weeks’ gestation.

Use while breast feeding is contraindicated in the SmPC (63). A Centers for Disease Control Expert Meeting on Malaria Chemoprophylaxis stated that doxycycline is excreted at low
concentrations in breast milk and that the American Academy of Pediatrics assessed tetracycline as compatible with breast feeding (64).

ACMP's view is that doxycycline should not be used in breast feeding unless other options are unsuitable, and its use is felt to be essential.

Cautions

The prescriber should warn against excessive sun exposure (and advise on the correct use of a broad-spectrum sunscreen).

Interactions
This section includes key interactions, but does not include all possible interactions. Practitioners should also consult the BNF and SmPC before prescribing.

Drugs: The metabolism of doxycycline is accelerated by carbamazepine and phenytoin. In that situation try to advise another antimalarial. If not possible or acceptable to the traveller, increase the dose of doxycycline to 100mg twice daily and counsel regarding measures to minimise the risk of adverse events. Tetracyclines possibly enhance the anticoagulant effect of coumarins (for example, warfarin), and doxycycline may increase the plasma concentration of ciclosporin.

Doxycycline is a non-enzyme-inducing antibiotic. The Faculty of Sexual and Reproductive Healthcare and the BNF advise that for combined oral contraceptives and for progestogen only oral contraceptives additional precautions are not required when using non-enzyme-inducing antibiotics. However, if the traveller suffers vomiting or diarrhoea, the usual additional contraceptive precautions should be observed.

Vaccines: Possibly reduces the efficacy of oral typhoid vaccine if given simultaneously. Preferably should not be started within 3 days after the last dose of vaccine.

Side-effects
Doxycycline hydrochloride preparations have a low pH and may produce oesophagitis and gastritis, especially if taken on an empty stomach and/or just before lying down.

Doxycycline may cause photosensitivity which is mostly mild and transient (56, 65).

Doxycycline is a broad-spectrum antibiotic and may predispose to vaginal candidiasis (56, 64).

Atovaquone plus proguanil combination preparation
Mode of action
Atovaquone works by inhibiting electron transport in the mitochondrial cytochrome b-c1 complex, causing collapse in the mitochondrial membrane potential. This action is potentiated
by proguanil and is not dependent upon conversion to its metabolite cycloguanil. Indeed, the combination remains effective in cycloguanil-resistant parasites (66). Atovaquone/proguanil prevents development of pre-erythrocytic (liver) schizonts (but not hypnozoites). It acts as a causal prophylactic agent, so needs to be continued for only 7 days after leaving a malarious area (67). It also has activity against the erythrocytic stages of malaria parasites and is useful for treatment.

**Efficacy**

Prophylactic efficacy against *P. falciparum* is 90% or more (68 to 76). There is less published data on protection against *P. vivax*, but data available indicate that atovaquone-proguanil is effective in the prevention of primary attacks of vivax malaria (75, 77). However, like chloroquine-proguanil, mefloquine and doxycycline, it will not protect against hypnozoite-induced episodes of *P. vivax* (or *P. ovale*) malaria. Formulations and method of administration Tablets containing proguanil 100mg and atovaquone 250mg. Paediatric tablets containing proguanil 25mg and atovaquone 62.5mg. To be taken orally with food or a milky drink.

**Prophylactic regimen**

Adult dose 1 tablet daily starting 1 to 2 days before entering a malarious area, continuing throughout the time in the area and for 7 days after leaving the area. ACMP does not support use of an abbreviated atovaquone-proguanil prophylaxis regimen in travellers after leaving malaria-endemic areas (78). Paediatric dose is given in Table 6. Maloff Protect, a brand of atovaquone plus proguanil combination preparation is available to purchase from UK pharmacies, after previously only being available on prescription.

They are available for adults aged over 18 weighing more than 40kg.

**Contraindications**

Allergy to proguanil or atovaquone or to any of the other ingredients in the tablets.

Renal impairment (avoid for malaria prophylaxis if eGFR less than 30 mL/minute/1.73m²).

**Cautions**

Atovaquone/proguanil should generally be avoided in pregnancy. The ACMP advises that if there are no other options, its use may be considered in the second and third trimesters after careful risk assessment. Inadvertent conception when using atovaquone/proguanil is not an indication to consider termination of the pregnancy, as no evidence of harm has emerged in data so far available (79, 92).

Atovaquone/proguanil should generally be avoided in breast feeding. The ACMP advises that atovaquone/proguanil can be used when breast-feeding if there is no suitable alternative antimalarial.

Diarrhoea or vomiting may reduce the absorption of atovaquone.
Guidelines for malaria prevention in travellers from the UK: 2022

Interactions
This section includes key interactions, but does not include all possible interactions. Practitioners should also consult the BNF and SmPC before prescribing.

For proguanil see proguanil section (above).

Drugs: Plasma concentrations of atovaquone are reduced by rifabutin and rifampicin, most non-nucleoside reverse transcriptase inhibitors, boosted protease inhibitors of HIV, tetracycline and metoclopramide (possible therapeutic failure of atovaquone, avoid concomitant use).

Atovaquone interacts with some antiretroviral drugs. For up-to-date information and an interaction checker see the HIV Drug Interactions website.

Vaccines
None reported.

Side-effects
The most frequent side-effects are headache and gastrointestinal upsets.

Dosage tables
These drugs are not listed in order of preference. The preferred prophylaxis is determined by a full risk assessment for each individual traveller.

Table 3. Prophylactic regimens against malaria in adults
3a. Areas of chloroquine-resistant \textit{P. falciparum}
3b. Areas of little chloroquine resistance; poorly effective where extensive resistance

<table>
<thead>
<tr>
<th>Regimen</th>
<th>Dose for chemoprophylaxis</th>
<th>Usual amount for tablet (mg)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Chloroquine plus Proguanil</td>
<td>Two tablets weekly plus Two tablets daily</td>
<td>155 (base) 100</td>
</tr>
</tbody>
</table>

For adults weighing 45kg or more. (For adults weighing less than 45kg please consult Table 4)

Table 4. Doses of prophylactic antimalarials for children (1)

<table>
<thead>
<tr>
<th>Weight in kilograms</th>
<th>Drug and tablet size</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Chloroquine base 155mg Proguanil 100mg Mefloquine 250mg Doxycycline 100mg</td>
</tr>
<tr>
<td>Under 6.0</td>
<td>0.125 dose ½ tablet 0.125 dose ¼ tablet See footnote2 Not recommended</td>
</tr>
<tr>
<td>6.0 to 9.9</td>
<td>0.25 dose ½ tablet 0.25 dose ¼ tablet 0.25 dose ¼ tablet Not recommended</td>
</tr>
<tr>
<td>10.0 to 15.9</td>
<td>0.375 dose ¾ tablet 0.375 dose ¼ tablet 0.25 dose ¾ tablet Not recommended</td>
</tr>
<tr>
<td>16.0 to 24.9</td>
<td>0.5 dose One tablet 0.5 dose One tablet 0.5 dose ½ tablet Not recommended</td>
</tr>
<tr>
<td>25.0 to 44.9</td>
<td>0.75 dose 1 to 1/2 tablets 0.75 dose 1 to 1/2 tablets 0.75 dose ¾ tablet Adult dose from age 12 years One tablet4</td>
</tr>
<tr>
<td>45 and over</td>
<td>Adult dose Two tablets Adult dose Two tablets Adult dose One tablet Adult dose One tablet</td>
</tr>
</tbody>
</table>

Note: Weight is a better guide than age for children, so weight should be used for the purpose of children’s dosage calculation including children who are over- or under-weight.

Further important notes

Doxycycline is unsuitable for children under 12 years irrespective of their weight. Caution: In other countries tablet strength may vary.

---

2 The SmPC for mefloquine indicates that it can be used for those weighing more than 5kgs. Therefore, mefloquine (0.25 dose, ¼ tablet) may be advised for children weighing 5 to 9.9kg.
3 For mefloquine at this weight, 0.375 dose would be preferable, but cannot be safely provided by breaking the adult tablet.
4 The adult dose is necessary when doxycycline is only available in capsule form and 3/4 is not feasible.
Atovaquone/proguanil paediatric dosage is given in Table 6.

Table 5. Table of doses by spoon or syringe\(^5\) measures for chloroquine syrup

<table>
<thead>
<tr>
<th>Weight in kilograms</th>
<th>Number of 5ml measures (there is often a half size measure at the other end of the spoon)</th>
<th>Proportion of adult dose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Under 4.5</td>
<td>0.5 (2.5 ml)</td>
<td>0.08</td>
</tr>
<tr>
<td>4.5 to 7.9</td>
<td>1.0 (5.0 ml)</td>
<td>0.16</td>
</tr>
<tr>
<td>8.0 to 10.9</td>
<td>1.5 (2.5 ml plus 5 ml)</td>
<td>0.24</td>
</tr>
<tr>
<td>11.0 to 14.9</td>
<td>2.0 (2 x 5 ml)</td>
<td>0.32</td>
</tr>
<tr>
<td>15.0 to 16.5</td>
<td>2.5 (2.5 ml plus 2 x 5 ml)</td>
<td>0.40</td>
</tr>
</tbody>
</table>

Note 1: These dose-steps are not the same as for chloroquine tablets, which differ from the syrup in chloroquine content. Chloroquine syrup contains 50mg chloroquine base in 5ml

Note 2: If chloroquine syrup is required for a child weighing more than 16.5kg please follow the dosage regimen stated in the BNFC.

Table 6. Table of paediatric doses of atovaquone/proguanil

See the section Children for advice on how to administer antimalarials to children. NaTHNaC has produced a useful summary table of children’s dosage.

---

\(^5\) Chemists may dispense dosing syringes for child doses.
Guidelines for malaria prevention in travellers from the UK: 2022

Country recommendations

ACMP recommendations by country are summarised in Table 7, below.

Key to Table 7
Table 7 contains the following abbreviations:
A/P = atovaquone-proguanil combination preparation
BA only = bite avoidance plus awareness of risk
C+P = chloroquine plus proguanil
D = doxycycline
M = mefloquine

Notes
1. The role of ACMP is to provide high level general guidance to help practitioners give specific advice for individual travellers
2. Bite avoidance is advised for travel to all areas, including the malaria-free areas of the countries listed in this table, as a preventive measure against other insect vector-borne diseases.
3. Some countries not listed in this table may experience occasional instances of malaria transmission. Please check the NaTHNaC or TRAVAX websites regularly for clinical updates.
4. A recommendation for bite prevention plus awareness of risk does not mean there is no risk of malaria in the place in question but indicates that ACMP considers the level of risk to be below the threshold for routinely recommending chemoprophylaxis. Where bite avoidance is now the main preventive measure for a given area, rigorous adherence to the recommendations in Bite prevention is strongly advised. In all cases, whether or not chemoprophylaxis has been advised, special attention must be given to bite prevention and febrile illness must be taken seriously and investigated promptly.
5. Long-term VFR visitors run a higher risk of catching malaria than short term travellers to the same location. Furthermore, once infected, the risk of developing severe or complicated malaria is higher in certain groups, such as the elderly (over 70 years old), the immunosuppressed, those with complex co-morbidities and pregnant women.
6. Although such travellers at increased risk of developing complicated malaria should not be offered antimalarials routinely for malaria risk areas where bite avoidance only is recommended, this may be considered in exceptional circumstances. Expert advice to support the practitioner is available from the MRL, NaTHNaC and TRAVAX.
7. The final decision whether or not to advise chemoprophylaxis rests with the travel health advisor and the traveller after individual risk assessment has been performed.

<td>There is a high risk of malaria in Somalia (A/P, D, M).</td>
</tr>
</tbody>
</table>
| South Africa (see Figure 52) | All travellers should take bite avoidance measures throughout the year in all risk areas. Transmission of malaria occurs typically between the months of September and May only.  
There is a risk of malaria in the low altitude areas of Mpumalanga and Limpopo particularly those bordering Mozambique, Eswatini and Zimbabwe; this includes the Kruger National Park: atovaquone/proguanil OR doxycycline OR mefloquine recommended during the transmission season, September to May only (see map provided by Department of Health, Republic of South Africa – marked as ‘moderate risk’).  
In June, July and August the risk in this area is considered to be very low: awareness of risk and bite avoidance recommended.  
There is a low risk of malaria in northeast KwaZulu-Natal and in designated areas of Mpumalanga, Limpopo (see map – marked as ‘low risk’) during the transmission season, September to May: awareness of risk and bite avoidance recommended.  
There is a very low risk of malaria in North West Province (adjacent to Molopo river) and Northern Cape Province (adjacent to Orange river): awareness of risk and bite avoidance recommended. |
<p>| South Korea          | There is a very low risk of malaria in the northern areas of South Korea, in Gangwon-do and Gyeonggi-do Provinces, and Incheon City (towards the Demilitarized Zone or DMZ) (BA only).            |
| South Sudan          | There is a high risk of malaria in South Sudan (A/P, D, M).                                                                                                                                                              |

**Emergency standby treatment**

Emergency standby treatment should be recommended for those taking chemoprophylaxis and visiting remote areas where they are unlikely to be within 24 hours of medical attention.

It is intended for those travellers who believe that they may have malaria and is not a replacement for chemoprophylaxis.

It is particularly important that the individual traveller is sufficiently well briefed to be able to use standby emergency treatment appropriately, as studies have shown that a significant proportion of travellers did not follow the pre-travel recommendations on administration of Emergency Standby Treatment, especially regarding the response to fever (80). Therefore, written instructions for its use are required (81).

Standby emergency treatment should be started if it is impossible to consult a doctor and/or reach a diagnosis within 24 hours of the onset of fever.

Medical attention should be sought as soon as possible for full assessment and to exclude other serious causes of fever. This is particularly important as many illnesses other than malaria may present with fever.

The traveller should complete the standby treatment course and recommence their antimalarial chemoprophylaxis one week after taking the first treatment dose. If quinine is used for standby treatment, mefloquine prophylaxis should be resumed at least 12 hours after the last treatment.
dose. Antipyretics should be used to treat fever. A second full treatment dose of the antimalarial should be taken if vomiting occurs within 30 minutes of taking it (half-dose if vomiting occurs after 30 to 60 minutes) (82).

The agent used for emergency standby treatment should be different from the drugs used for chemoprophylaxis, both to minimise drug toxicity and due to concerns over drug resistance (83).

Individuals for whom emergency standby treatment is advised must be provided with written instructions for its use. In particular, they must be informed about symptoms suggesting possible malaria, including fever of 38°C and above, indications for starting the standby treatment, how to take it, expected side-effects and the possibility of drug failure (83). ACMP recommended regimens for emergency standby treatment are given in Table 8.

Dihydroartemisinin-piperaquine has only recently been licensed in the EU and there are limited data on its use in travellers, so it cannot currently be recommended for this indication. Sulfadoxine/pyrimethamine (SP) is not recommended due to reports of widespread resistance to this agent among P. falciparum strains. Halofantrine is no longer recommended due to concerns over its association with sometimes fatal cardiac arrhythmias (83).

Antimalarials purchased in the tropics may be fake (45) and travellers should obtain the medication required for their emergency standby treatment from a reputable source in the UK before they travel. ACMP also advises those purchasing antimalarial drugs over the internet to ensure that they are dealing with a bona fide supplier or website.

</table>

* Pregnant travellers should avoid malarious areas. If that is not possible, quinine plus clindamycin is the only regimen to be used in the first trimester of pregnancy. Artemether plus lumefantrine combination preparation can be used in the second and third trimesters.

See Appendix 3 for an emergency standby medication traveller information leaflet which can be copied and pasted for use.
Diagnosis

Suspected malaria is a medical emergency.

Consider malaria in every ill patient who has returned from the tropics in the previous year, especially in the previous 3 months.

Fever on return from the tropics should be considered to be malaria until proven otherwise.

Malaria cannot be diagnosed with certainty by clinical criteria alone. Suspected cases should be investigated by obtaining a blood film diagnosis as a matter of urgency.

There is no need to wait for fever spikes before taking blood; this only delays diagnosis and the fever pattern seldom conforms to textbook periodicity, especially in the case of *Plasmodium falciparum*.

Blood tests and how to request them in the UK

An EDTA-anticoagulated venous blood sample should be taken.

The test request form should include the phrase ‘Urgent, suspected malaria’ and the form and the blood sample should be received in the laboratory within 1 hour of being taken as falciparum malaria may increase in severity over a few hours and the morphology of malaria parasites in EDTA deteriorates over time, rendering accurate laboratory diagnosis more difficult.

Finger-prick samples smeared directly onto microscope slides at the bedside are sub-optimal for modern diagnosis as the laboratory then has no additional material to make and stain further smears, undertake rapid diagnostic tests (RDTs) or refer for PCR testing.

Laboratories in England, Wales and Northern Ireland making a diagnosis of malaria should send blood films and a portion of the blood sample on which the diagnosis was made to the UKHSA Malaria Reference Laboratory (MRL). Laboratories in Scotland should refer to the Scottish Parasite Diagnostic Laboratory.

Rapid diagnostic tests (RDTs)

RDTs (sometimes known as ‘dipsticks’) can be used successfully in trained, selected high-risk groups (84) but ACMP does not recommend routine use of RDTs for self-diagnosis by travellers.

RDTs permit the detection of malaria parasites in human blood without microscopy. Used correctly, they can confirm the clinical diagnosis of malaria in places remote from medical
attention (85). However travellers may use them incorrectly and thus fail to detect parasites (86).

RDTs do have a place in the medical kit carried by a doctor or nurse accompanying an expedition to remote malarious regions. Performance of RDTs may be impaired if they are stored at temperatures outside the recommended range (87). Therefore, care must be taken to transport and store them correctly and thus prevent deterioration in their performance in the field.

Furthermore, a study of self-diagnosis by travellers and expatriates using RDTs available on the internet showed the particular RDTs used had variable diagnostic accuracy. Only 4 of 8 RDT products for self-diagnosis were judged reliable for the diagnosis of *P. falciparum* and *P. vivax* and none for *P. ovale* and *P. malariae* (88).

Appropriate choice of RDT product is therefore crucial and the WHO has an extensive product testing programme for RDTs. Prospective purchasers should consult the WHO web site for information to inform their decision.

**Blood film and/or RDT negative malaria**

One negative blood film or RDT does not exclude a diagnosis of malaria. RDTs are not a substitute for microscopy in UK practice, but have a useful role alongside blood films as additional tests.

Where malaria is suspected blood films should be examined daily for 3 days whilst other diagnoses are also considered. If all these films are negative and malaria is still considered a possible diagnosis, expert advice should be sought from a specialist in tropical or infectious diseases. It is particularly important to seek such advice early in the care of pregnant patients with suspected malaria, as most parasites may be sequestered in the placenta such that peripheral blood films are negative despite the patient having malaria (see Information resources for expert advice listing).

**Resources for treatment advice**

The treatment of malaria is outside the scope of this document and is addressed in the ACMP malaria treatment guidelines.

Expert advice on malaria treatment may be obtained from:

- Hospital for Tropical Diseases
- Liverpool School of Tropical Medicine
- your local infectious diseases unit
Notification

Malaria is a statutorily notifiable disease in England and Wales and the clinician caring for the patient must complete a notification form (89). In Scotland, malaria is not on the list of notifiable diseases, but Plasmodium is on the list of notifiable organisms. UK laboratories outwith Scotland are also required to notify organisms they have diagnosed. The legislation for notifiable organisms places duties on directors of diagnostic laboratories to report organisms named in the list.

In England and Wales, the Malaria Reference Laboratory (MRL) reporting form (should also be completed and sent to the MRL separately or along with referred specimens.
Special groups (medical conditions)

Smoking cessation

Chloroquine or mefloquine should not be used in those taking Zyban® (bupropion hydrochloride SR) as the chances of seizure may be increased.

Pregnancy

Pregnant women are advised to avoid travel to malarious areas.

Pregnant women have an increased risk of developing severe malaria and a higher risk of fatality compared to non-pregnant women.

If travel is unavoidable, the pregnant traveller must be informed of the risks which malaria presents and the risks and benefits of antimalarial chemoprophylaxis.

Diagnosis of falciparum malaria in pregnancy can be particularly difficult as parasites may not be detectable in blood films due to sequestration in the placenta.

Expert advice is required at an early stage if malaria is suspected in a pregnant woman. Complications, including severe anaemia, hypoglycaemia, jaundice, renal failure, hyperpyrexia and pulmonary oedema, may ensue. The result may be miscarriage, premature delivery, maternal and/or neonatal death.

Congenital malaria is rare but occurs more commonly with *P. vivax* than with the other malaria parasites of humans.

Avoidance of mosquito bites is extremely important in pregnancy as pregnant women are particularly attractive to mosquitoes. Ideally, pregnant women should remain indoors between dusk and dawn. If they must be outdoors at night they should adhere rigorously to bite precautions (see Bite prevention).

DEET should be used in a concentration of not more than 50%. DEET has a good safety record in children and pregnancy (35) but ingestion should be avoided. Nursing mothers should wash repellents off their hands and breast skin prior to handling infants. See Bite prevention for further details on DEET.

Chloroquine and proguanil

Safe in all trimesters of pregnancy. Their major disadvantage is the relatively poor protection they give in many geographical areas due to the presence of drug-resistant *P. falciparum*.
Pregnant women taking proguanil should receive supplementation with 5mg folic acid daily for the length of time that proguanil is taken.

**Mefloquine**

Caution in first trimester but can be used in all trimesters for travellers to high risk areas. It seems unlikely that mefloquine is associated with adverse foetal outcomes (86, 87, 85).

A review of the manufacturer's global drug safety database covering 1986 to 2010 showed that for mefloquine exposure in pregnancy, the birth defect prevalence and foetal loss in maternal, prospectively monitored cases were comparable to background rates (90).

The decision whether to advise mefloquine prophylaxis in pregnancy always requires a careful harm-benefit analysis. Where the levels of transmission and drug resistance (see country tables in Chemoprophylaxis) make mefloquine an agent of first choice, it is generally agreed that mefloquine may be advised in the second and third trimesters of pregnancy.

Given the potential severity of falciparum malaria in a pregnant woman, its use is also justified in the first trimester in areas of high risk of acquiring falciparum malaria such as sub-Saharan Africa (see Information resources).

Women who have taken mefloquine inadvertently just prior to or during the first trimester should be advised that this does not constitute an indication to terminate the pregnancy (91).

**Doxycycline**

Contraindicated in pregnancy. However, under special circumstances, if required before 15 weeks' gestation it should not be withheld if other options are unsuitable. The course of doxycycline, including the 4 weeks after travel, must be completed before 15 weeks’ gestation.

**Atovaquone/proguanil**

Lack of evidence on safety in pregnancy. Animal studies showed no evidence for teratogenicity of the combination. The individual components have shown no effects on parturition or pre and post-natal development (Malarone SmPC).

A registry-based study of the inadvertent use of atovaquone-proguanil in weeks 3 to 8 after conception identified 149 pregnancies and found no significant association between exposure to atovaquone-proguanil in early pregnancy and the risk of a major birth defect (79).

An anonymous, internet-based survey to describe outcomes of pregnancies accidentally exposed to atovaquone-proguanil identified 10 who had atovaquone–proguanil exposure in the first trimester. All resulted in term births with no birth defects (92).
A study of 198 women who received atovaquone-proguanil in pregnancy or breastfeeding, 79.8% of them in the first trimester, did not show a specific signal to suggest a teratogenic effect, but numbers were too small confidently to determine safety of this combination in pregnancy (93).

A systematic review of the safety of atovaquone-proguanil for malaria prevention and treatment in pregnancy suggested that the rates of adverse events are not higher than the expected rates in similar populations (94).

A retrospective analysis of risk for adverse fetal and infant outcomes after atovaquone-proguanil exposure in pregnancy was unable to reach a definitive conclusion, but highlighted a clear need for further research (95).

ACMP does not currently advise the use of atovaquone/proguanil for antimalarial chemoprophylaxis in pregnancy due to sparse data. However, if there are no other appropriate options, its use may be considered in the second and third trimesters after careful risk assessment.

Folic acid 5mg daily should be taken for the length of time that atovaquone/proguanil is taken in pregnancy and also by those taking atovaquone/proguanil who are seeking to become pregnant.

Women who have taken atovaquone/proguanil inadvertently just prior to or during the first trimester should be advised that this does not constitute an indication to terminate the pregnancy.

For a useful recent review of malaria in the pregnant traveller, see reference 96.

**Chemoprophylaxis prior to conception**

If a female traveller is planning to conceive during a visit to a destination with a high risk of contracting chloroquine-resistant falciparum malaria, expert advice should be sought. Use of mefloquine may be considered after careful risk assessment.

Those travellers who plan to become pregnant after taking antimalarials and who wish to do so with minimal antimalarial drug present, may elect to observe the following time intervals after completing the course, before attempting to conceive:

- Mefloquine – 3 months
- Doxycycline – 1 week
- Atovaquone/proguanil – 2 weeks
Breastfeeding

Mefloquine

Experience suggests safe to use during lactation.

Doxycycline

The British National Formulary states that tetracyclines should not be given to women who are breast feeding (63). A Centers for Disease Control Expert Meeting on Malaria Chemoprophylaxis stated that doxycycline is excreted at low concentrations in breast milk and that the American Academy of Pediatrics assessed tetracycline as compatible with breast feeding (64). ACMP's view is that doxycycline should not be used in breast feeding unless there is no alternative agent and its use is felt to be essential.

Atovaquone/proguanil

Not recommended because of the absence of data however, can be used when breast-feeding if there is no suitable alternative antimalarial.

Breast-feeding mothers should be advised to take the usual adult dose of antimalarial appropriate for the country to be visited.

The amount of medication in breast milk will not protect the infant from malaria. Therefore, the breastfeeding child needs his or her own prophylaxis. See Tables 4, 5 and 6 for paediatric doses.

Anticoagulants

The coumarins, including warfarin

Travellers should ensure their INR (International Normalised Ratio) is stable and within the therapeutic range prior to departure and they have adequate supplies of their anticoagulant for the whole trip. Changes in diet and alcohol intake can affect the INR.

Patients on warfarin may have underlying cardiovascular disease and may be on cardiovascular medication. Interactions with other medication together with the individuals' medical history should be taken into account when deciding on appropriate malaria chemoprophylaxis.

Chloroquine

No interaction between warfarin and chloroquine documented in the BNF.

Proguanil

An isolated report of an enhanced effect of warfarin when taken together with proguanil (97).
Mefloquine
Not considered to be a problem for those taking warfarin. The manufacturer states that: “although no drug interaction is known with anticoagulants, effects of mefloquine on travellers should be checked before departure.” See below for how this can be monitored.

Doxycycline
The anticoagulant effect of coumarins (including warfarin) is possibly enhanced by tetracyclines (63).

Atovaquone/proguanil
Unknown whether there are interactions between atovaquone/proguanil and warfarin, although there has been an isolated report of an enhanced effect of warfarin when taken together with proguanil (see above under proguanil).

Advice for travellers needing malaria chemoprophylaxis who are taking warfarin
Travellers should inform their anticoagulant clinic and start taking their malaria tablets 2 to 3 weeks prior to their departure.

A baseline INR should be checked prior to starting chemoprophylaxis and re-checked after 1 week of taking chemoprophylaxis to determine whether the warfarin dosage needs to be adjusted. The traveller must check with their anticoagulant clinic to see if their INR is appropriate for travel. If a traveller is away for a long period of time the INR should be checked at intervals at the destination. However, the sensitivity of thromboplastin reagent used by some laboratories in different countries may vary (98). Self-monitoring of the INR may be suitable for some travellers, but must be under the supervision of an anticoagulant clinic (99). INR self-testing devices are readily available and can be used safely by experienced patients. Expert patients, defined as such by their anticoagulant clinic, can undertake self-management. Other patients may perform INR self-testing and stay in contact with their home anticoagulant clinic for dosage recommendations (99). Given modern communication methods it should be possible to keep-in touch from many malaria-endemic areas.

Once chemoprophylaxis has been completed, the INR should be checked again to re-stabilise anticoagulant therapy.

Direct oral anticoagulants (DOAC)
Dabigatran etexilate, rivaroxaban, apixaban and edoxaban are the most commonly available DOAC. They do not interact with food, do not require laboratory monitoring and have a lower potential for drug interactions than the coumarins (see below) (100).

There is relatively limited experience of antimalarial chemoprophylactic use by those taking DOAC.

Apixaban and rivaroxaban are substrates of CYP3A4 and p-glycoprotein. Dabigatran is a substrate of p-glycoprotein.
Mefloquine inhibits CYP3A4 and p-glycoprotein, so could increase DOAC plasma concentrations which might lead to an increased bleeding tendency (100).

Atovaquone may produce minor inhibition of CYP3A4. The effect of proguanil on this enzyme is unknown.

Neither atovaquone nor proguanil inhibits p-glycoprotein (100).

In addition to following this guideline, please consult the drug interactions section of the latest edition of the BNF. If doubt exists after taking these steps, seek expert advice from a haematologist.

**Epilepsy**

Note: A history of febrile convulsions only does not contraindicate use of any of the currently available malaria chemoprophylactic drugs. The following advice applies to travellers with epilepsy where restrictions do apply.

In epilepsy:

- doxycycline or atovaquone/proguanil can be used
- chloroquine is unsuitable
- mefloquine is unsuitable

**Doxycycline**

Half-life may be reduced by phenytoin, carbamazepine, and barbiturates. Try to advise another antimalarial. If not possible or acceptable to the traveller, increase the dose of doxycycline to 100mg twice daily and counsel regarding measures to minimise the risk of adverse events.

**Glucose 6-phosphate dehydrogenase deficiency**

Glucose 6-phosphate dehydrogenase (G6PD) is an enzyme that helps protect the red cell against oxidative damage. Absence of G6PD renders the red cell liable to haemolysis in the presence of some drugs.

All G6PD-deficient travellers to malarious areas should take appropriate chemoprophylaxis despite some protection against infection being conferred by the most common G6PD deficiency allele in Africa (G6PD A-) (101).

**Chloroquine**

Theoretical risk of haemolysis in some G6PD-deficient individuals. Haemolysis does not appear to be a problem when chloroquine is given in the dose recommended for malaria chemoprophylaxis so there is no need to withhold chloroquine prophylaxis from those known to
be G6PD-deficient. This risk is acceptable in acute malaria (63) and G6PD levels are not usually checked before using chloroquine in treatment doses.

**Atovaquone-proguanil, doxycycline, mefloquine or proguanil**

There is no need to withhold any of these agents from those known to be G6PD-deficient.

**Primaquine**

Not currently recommended as a first line agent for malaria prevention in UK travellers, but may be considered in special circumstances on expert advice (48). There is a definite risk of haemolysis in G6PD-deficient individuals. The traveller’s G6PD level must be checked before primaquine is prescribed: G6PD deficiency contraindicates its use for prophylaxis.

**Sickle cell disease and thalassaemia (102)**

Presence of the sickle cell trait confers some protection against malaria, though individuals with the sickle cell trait still require antimalarial prophylaxis.

For those with homozygous sickle-cell disease, malaria is regarded as a significant cause of morbidity and mortality, producing further haemolysis against the background of that due to sickle cell disease itself. Therefore, it is essential that individuals with sickle cell disease travelling to malaria-endemic areas receive rigorous antimalarial protection.

Thalassaemia may provide protection against severe malaria, but there is currently no evidence it prevents uncomplicated malaria.

**Immunocompromised travellers**

**Risks for transplant patients**

A review on the prevention of infection in adult travellers after organ transplantation (103) recommended that ciclosporin levels should be monitored if chloroquine is co-administered.

**Risks for those living with HIV**

HIV protease inhibitors (PIs) as well as the non-nucleoside reverse transcriptase inhibitors (NNRTIs) can either inhibit or induce the same liver enzymes which metabolise most drugs used for malaria prophylaxis and treatment. Potentially this could result in altered metabolism of some antimalarials, though the extent of this and the clinical significance is often unclear, as data are limited. Doxycycline is the simplest chemoprophylaxis against malaria for most people on antiretrovirals.
However, information in this area is accumulating rapidly and the travel health adviser should check the manufacturer's SmPC and the BNF on an individual agent basis and should discuss and agree their recommendation for chemoprophylaxis with the traveller’s own HIV physician.

Up-to-date information can also be obtained from the University of Liverpool site where it is possible to look up specific antiretroviral compounds against malaria prophylactic drugs in readily-accessible tables.

Most reported studies of malaria and HIV co-infection have been done in those living in endemic areas where HIV infection increases the risks for contracting and developing severe malaria and increasing immunosuppression reduces treatment success (104) although this varies by area (105).

A study of imported malaria in France reported that severe malaria in HIV-1 infected patients was associated with decreased CD4 cell count (106).

Co-infected pregnant women are at risk from higher parasite density, anaemia and malarial infection of the placenta.

Children born to women with HIV and malaria infection have low birth weight and are more likely to die during infancy. Malaria during pregnancy increases the risk of mother-to-child transmission of HIV-1 (107).

**Liver disease**

Most antimalarial drugs are excreted or metabolised by the liver. Thus, there is a risk of drug accumulation in severe liver impairment.

**Severe liver disease**

A CDC expert meeting concluded that the dose of doxycycline does not have to be adjusted in patients with impaired hepatic function since it is excreted as an inactive chelated product via a process of back diffusion in the small bowel (64). Note to prescribers: The BNF states that tetracyclines should be avoided or used with caution in patients with hepatic impairment. The manufacturer of atovaquone-proguanil combination preparation states that although no pharmacokinetic studies have been conducted in severe hepatic impairment, no special precautions or dosage adjustment are anticipated (SmPC).

Mefloquine is contraindicated in severe hepatic impairment (SmPC).

**Moderate impairment**

Doxycycline, proguanil, or atovaquone-proguanil combination preparation, or mefloquine may be used.
Mild impairment

Chloroquine, or proguanil, or chloroquine plus proguanil, or atovaquone-proguanil combination preparation, or mefloquine, or doxycycline may be used.

The choice of chemoprophylaxis should be made after discussion with the patient’s specialist, who will be able to assess their degree of hepatic impairment.

The Child-Pugh classification is often used for grading liver function and can be found at the Liverpool Medics website or the US Department of Veteran Affairs website.

Renal impairment

Chloroquine is partially excreted via the kidneys while proguanil is wholly excreted via the kidneys.

Chloroquine

Dose reduction for prophylaxis is required only in severe renal impairment.

Proguanil

Should be avoided or the dose reduced as shown in Table 9. Not to be used in patients receiving renal dialysis.

Atovaquone/proguanil

Not recommended for patients with an eGFR of less than 30mL/minute (63). Not to be used in patients receiving renal dialysis

Doxycycline or mefloquine

May be used in severe renal failure. There is no need to reduce the dose of mefloquine in renal dialysis (63).

Splenectomy

Those who have no spleen or whose splenic function is severely impaired are at particular risk of severe malaria and, where possible, should avoid travel to malarious areas.

If travel is essential, every effort should be made to avoid infection by rigorous use of antimosquito precautions and strict adherence to appropriate chemoprophyaxis, even in BA only malarious areas, apart from those areas regarded as very low to no malaria risk, where BA only would still apply. If the traveller becomes unwell during or after their visit, medical attention is required as a matter of urgency, as malarial parasitaemia in asplenic individuals may rise rapidly to very high levels (for example, greater than 50% with *P. falciparum*).

Acute porphyrias

Doxycycline is unsafe in porphyria (63) so should not be used for antimalarial chemoprophylaxis in patients with acute porphyria.
Special categories

Children

Children are at particular risk of severe and fatal malaria; therefore, parents are advised against taking infants and young children to malarious areas without adequate precautions.

If travel is unavoidable, infants and children should be well protected against mosquito bites and receive appropriate malaria chemoprophylaxis.

It is important that the child’s carers understand the importance of trying to ensure that the child properly completes the full course of prophylactic medication.

Parents should supervise children’s chemoprophylaxis, as some regimens can be difficult even for adults to follow.

Parents must be cautious not to exceed maximum recommended doses, since antimalarials can be particularly toxic to children.

Paediatric doses of antimalarials for prophylaxis are shown in Tables 4, 5 and 6 in Chemoprophylaxis.

Chloroquine

Take care to ensure that tablets are swallowed, as they have a bitter taste. Sweetened chloroquine syrup is available. Store safely away from children since an overdose can be fatal.

Proguanil

Difficult to use for children since proguanil is only available in adult formulations and, dependent on the weight of the child, the adult-dose tablets must be broken and powdered into food.

Chloroquine plus proguanil

See individual agents above.

Mefloquine

Problem in administering correct dosage because there is currently no suspension available and adult-dose tablets must be broken.

Doxycycline

Only licensed in the UK for children over the age of 12 years due to its potential to cause bone damage and discolouration of teeth. This age limit varies between countries; tablets should be swallowed whole and must not be crushed.
Atovaquone-proguanil combination preparation

Paediatric tablets are licensed in the UK for malaria prophylaxis in children from 11kg upwards. For children weighing less than 11kg, ACMP recommends a dosage regimen of:

- weight 5 to 7.9kg – half a paediatric tablet daily
- weight 8 to 9.9kg – three-quarters of a paediatric tablet daily

Whilst it is preferable to avoid breaking and crushing tablets, the appropriate dose of proguanil or mefloquine or atovaquone-proguanil combination preparation may be broken if dosing requires it and the drugs crushed if necessary and mixed with jam, honey, pasteurised yoghurt or similar food to aid administration to young children. Tablet-cutters can be purchased from some pharmacies or travel shops. If further advice is required a dispensing pharmacist should be consulted.

Children with malaria may deteriorate very rapidly to become critically ill. Those looking after children on their return from malarious areas including: family members, friends, professional carers, or school nursing and medical staff should be made aware that such children need medical attention and a blood test for malaria without delay if they become unwell within a year of leaving a malarious area.

Healthcare professionals should strive to improve access to advice on malaria prevention for families with children, especially travellers visiting friends and relatives (108).

Elderly travellers

The elderly are at particular risk of dying from malaria once acquired (82). No reduction in antimalarial dosage is required on the basis of advanced age. However, elderly travellers are more likely to have underlying disorders, for example, renal impairment, which may necessitate antimalarial dose reduction. Furthermore, the increased likelihood of elderly travellers taking additional medication, for example, for cardiac conditions, will influence the choice of chemoprophylactic agent in their particular case.

Of concern, a recent systematic review of malaria prevention in the older traveller concluded that older travellers seem less likely to comply with bite-prevention measures (109). Given the good safety profile of such measures, every effort should be made to improve their uptake by elderly travellers.

As the UK population ages yet further, the number of individuals suffering from cognitive decline will increase. Travel health practitioners need to be aware of this possibility when conducting pre-travel malaria risk-assessments for the elderly. Much more work is needed in this area across the whole of travel medicine practice.
Multi-trip travel

Some travellers – for example, business persons or expatriate contract employees – may make several short visits to malarious areas in the same year. For instance, someone working in the tropics 4 weeks on, 4 weeks off, might be taking chemoprophylaxis for most or all the year when including the periods before and after travel that prophylaxis is required.

The strategy for chemoprophylaxis will then be mainly influenced by the level of malaria risk in the areas to be visited. For example, in the highly malarious regions of West Africa, the risk-benefit assessment is strongly in favour of taking chemoprophylaxis, even if it means year-round administration. For less frequent trips, the regions visited should determine the chemoprophylactic agents from which to choose.

When the choice lies between mefloquine or doxycycline or atovaquone-proguanil combination preparation and the traveller wishes tablet-free periods between visits, the shorter period of 7 days post exposure for atovaquone-proguanil combination preparation prophylaxis versus the alternatives may be helpful.

Cruises

All travellers on cruises should use insect bite avoidance measures.

Cruises are a growing part of the holiday market. Most travellers on cruises are only ashore during daylight hours when Anopheles bites rarely occur, and therefore do not require malaria chemoprophylaxis. However, the cruise itinerary must be reviewed carefully to determine the risk of exposure to malaria.

For example, cruises along the East African coast may include a stop for a night or more in the port of Mombasa in Kenya and passengers may be ashore or on deck after dusk. These itineraries will require malaria chemoprophylaxis.

In addition, cruises that have an overnight stay in any other malaria endemic region of the world may require malaria chemoprophylaxis.

Oil rigs

Many staff are employed in the oil industry, predominantly based around West Africa. Employees commonly travel to these areas every 4 to 6 weeks, followed by a similar period of leave back in the UK. Oil rigs may be based in river estuaries or many miles offshore. Thus, the level of risk may be difficult to assess until one period of work has been completed, so antimalarial chemoprophylaxis should be taken for the whole of this first trip, by when the situation will be known, and then be reviewed for subsequent trips.
Guidelines for malaria prevention in travellers from the UK: 2022

Antimalarial chemoprophylaxis is advised for workers on oil rigs based in river estuaries.

Offshore rigs pose little risk and antimalarial chemoprophylaxis may only be needed if staying overnight onshore during transit.

Visits to national parks

Travellers visiting countries where malaria is restricted in distribution may plan to make day trips to national parks in malarious regions of the country. They should be advised on awareness of risk, bite precautions and the need for prompt attention in the event of fever during the succeeding year. If they plan to stay overnight in the malarious area – for example, in a safari lodge – they should also take chemoprophylaxis.

Stopovers

Many stopovers are in urban or tourist areas (particularly in Asia) and have minimal malaria risk. They are often situated in countries which may have malaria transmission in parts. Therefore, to assess risk, it is essential to establish where overnight accommodation will be.

Stopovers after dark in most of sub-Saharan Africa, including main cities, present a risk of malaria and antimalarial prophylaxis should be recommended.

Stops to change or refuel aircraft do not usually require chemoprophylaxis, but it may be considered if the trip entails an overnight stop away from the airfield (assessed as above).

Last minute travellers

Last minute visits to malarious regions, whether for vacation, business or family reasons, are now commonplace. This may leave the traveller little time to seek and act on travel advice.

Maloff Protect, a brand of atovaquone plus proguanil combination preparation is available to purchase from pharmacies, whereas atovaquone plus proguanil was previously only available on prescription. Maloff Protect is available for adults aged over 18 weighing 40kg and above.

Retail pharmacy outlets can also supply over-the-counter antimalarials (chloroquine and/or proguanil) though they are now less often used, as well as antimosquito products.

Mefloquine and doxycycline and for those less than 18 years old atovaquone-proguanil combination preparation, are currently prescription-only medicines (POMs), but some pharmacists are now prescribers and thus able to prescribe these POMs. Some retail pharmacy outlets also supply these POMs under PGDs.
If the traveller cannot obtain a GP appointment at short notice, some commercial travel clinics cater for walk-in attendees.

Doxycycline or atovaquone-proguanil combination preparation should be started 2 days before travel to a malarious area. Chloroquine or proguanil or chloroquine plus proguanil 1 week before, and mefloquine 2 to 3 weeks before (to ensure tolerance).

Nevertheless, it is better to start chemoprophylaxis late than not to take it at all, as suppressive prophylactics will begin to work by the end of the malaria incubation period.

Where the recommended choice for the region to be visited is mefloquine or doxycycline or atovaquone-proguanil combination preparation, it would be sensible to avoid mefloquine for last-minute prophylaxis as it takes time to reach steady state, and especially if the traveller has not taken and tolerated mefloquine in the past.

ACMP does not recommend loading doses of any prophylactic antimalarial. The dosages recommended in these guidelines should be followed.

**Visiting friends and relatives**

See [Visiting friends and relatives abroad: health advice](#).

(Adapted from the HPA Migrant Health Report 2006 (110) updated 2011 (111). See also the Office for Health Improvement and Disparities Migrant Health Guide (112))

In the UK, malaria predominantly affects the non-UK born population and their families, particularly those from Africa and south Asia, largely due to their high rates of travel to malarious areas. Much greater effort is needed to convey health prevention advice to this key group. Data suggest that people visiting friends and relatives (VFR travellers) are significantly less likely to take antimalarial prophylaxis than other travellers to Africa. Reasons for this may be that those visiting friends and relatives in Africa substantially underestimate the risk of acquiring malaria and overestimate the amount of protection that having been brought up in Africa may give them.

Awareness needs to be raised that malaria is not a trivial disease. Those born in malarious countries need to be aware that any immunity they may have acquired is rapidly lost after migration to the UK. The view that this group is relatively protected is a dangerous myth. Migrants from malarious areas also need to be made aware that second-generation members of their families have no clinically relevant immunity to malaria, and that their children are particularly vulnerable.

Effective chemoprophylaxis taken correctly reduces the risk of malaria by around 90%, especially if combined with sleeping under insecticide-treated nets.
Appropriately tailored health information should be targeted to migrant communities, especially of African descent, to stress the importance of chemoprophylaxis. Community-based participatory work can identify barriers to malaria prevention in VFR travellers and help implement suitable interventions (113). Health advisers for this group, including primary care practitioners working in areas with large numbers of migrants, can have a major role to play via opportunistic discussions during visits to the practice undertaken for other reasons.

Those who feel unwell following any trip to tropical areas should be encouraged to present to their doctors early, and to inform the doctors that they are at risk of malaria. Patients of African origin, and occasionally doctors, can underestimate the severity of malaria in this group.

**Students and children at boarding school**

Many people from malaria-endemic areas come to the UK for secondary or higher education.

Those who stay in Britain for a year or more will lose a significant degree of any malarial immunity they had acquired and become more susceptible to clinical malaria. When they return home, they should be advised as for the section The long-term traveller to the UK returning to live in malarious parts of the world.

Those who are making short visits home (for example, in school or college vacations) should be considered as VFR travellers and should be advised to use chemoprophylaxis in addition to personal protective measures against mosquito bites.

Students may become infected during their school or college vacations, but the first symptoms of clinical malaria may occur in term time whilst they are in the UK. Therefore, it is essential that school and/or college nursing and medical staff consider malaria from the outset in any pupil from, or with a history of travel to, a malarious region and arrange a blood test for malaria without delay.

Adherence to antimalarial chemoprophylaxis is reported as poor in children who return home to malarious areas. This may be due to a lack of understanding that children who reside in the UK are at increased risk of acquiring malaria when they return home to malarious areas, compared to those who live there permanently.

Provision of specific written instruction and advice for the parents may be helpful and could include the following:

- children who reside in the UK lose natural immunity to malaria and are at increased risk of acquiring malaria compared to those who live permanently in malarious areas
- antimalarial chemoprophylaxis is recommended for children in UK boarding schools in accordance with UK ACMP guidance
- where chemoprophylaxis is taken correctly, along with all other malaria prevention measures, the risk of a child acquiring malaria will be significantly reduced
• parents should support advice given to children in the UK and should encourage adherence to the recommended antimalarial chemoprophylaxis

• where possible, the course of tablets supplied in the UK should be completed and not substituted with different tablets at the destination

• where tablets provided in the UK must be replaced with different tablets at the destination (for example, if they are lost or side effects occur) information on the replacement medication should be supplied to the nurse in writing when the child returns to the UK. This is important especially if the child becomes unwell after return and requires treatment with other medication

The long-term traveller

Risk assessment

The long-term traveller is defined here as those travelling through or visiting malaria-endemic countries for over 6 months.

One major problem for the long-term traveller is the variable access to and quality of medical care available overseas (114). The provision of details of healthcare facilities or points of information could be crucial.

The main issues influencing the choice of malaria chemoprophylaxis on a long-term basis are the same as for short-term use, that is malaria risk, adverse events profile, compliance and efficacy. However, the licensing criteria for antimalarial drugs often restrict the recommended periods of administration (usually due to a lack of formal trials of long-term administration, rather than from evidence of adverse effects). This leads to uncertainty about the safety of long-term prescribing.

A decision on whether chemoprophylaxis is continued on a long-term basis may be influenced by the overall length of stay, seasonal risk in the area, and access to medical facilities.

Travellers living or backpacking in rural areas may be far from appropriate medical attention and the need for standby emergency medication should also be considered. The continued use of chemoprophylaxis will also depend on current personal health, current medication, previous medical history and relevant family medical history. However, long-term travellers are at high risk from malaria, and should not neglect necessary prophylaxis.

Health risks for the long-term traveller will vary considerably, depending in part on the reasons for travel including:

Visiting friends and relatives (VFR)

Individuals who originate from countries where malaria is transmitted, but who have settled in the UK. They may later visit their country of origin and remain there for long periods of time while working or visiting friends and relatives. They may perceive little risk from malaria infection or believe they are immune. This is not true (see the section on Visiting friends and relatives).
Guidelines for malaria prevention in travellers from the UK: 2022

Expatriates
Usually based at a single location where the risk of malaria is known, they often have access to medical care, a good standard of accommodation and are usually more aware of the malaria risks. However, up to 30% of some expatriates develop malaria within 2 years and many cases can be attributed to poor compliance with prophylaxis (115).

Backpackers
Often younger than expatriates, they may be less careful of their personal safety and less adherent to medical advice, in addition to having less experience of overseas travel in general. They have less control over their environment as they are constantly moving on.

Chemoprophylaxis for long-term travellers

Adverse events
The cumulative risk of contracting malaria is roughly proportional to the length of stay in a malarious area over the first few months. A 3-month visit carries a risk around 6 times greater than a visit of 2 weeks.

While the risk of new adverse events falls off over time, the risk of contracting malaria continues to increase roughly linearly as exposure to malaria continues (see Figure 7). Thus, chemoprophylaxis in highly malarious areas is even more important for long-term visitors than it is for short-term travellers. Indeed, long-term travellers may wish to consider using malaria prophylaxis, or have standby medication, when short-term travellers might not, because of their sustained exposure to a small risk of infection.

Adherence to chemoprophylaxis
Compliance has been shown to decrease with the duration of travel (116), except where military-style discipline tends to support compliance. There is also evidence of weekly regimens having increased adherence over daily regimens (116). Long-term adherence decreases for both daily and weekly prophylactic regimens (64).

Possible reasons for reduced compliance in long-term travellers may include:

- fear of long-term side effects
- actual adverse events on one or more regimens
- conflicting advice
- complex regimen or daily tablets
- reduced confidence if intercurrent fever misdiagnosed as malaria
- perception from anecdotal evidence that chemoprophylaxis is unnecessary (117)

In addition, long-term travellers may overlook personal protective measures against mosquitoes (118).
Efficacy of regimens
It is important to stress that no chemoprophylactic regimen is 100% effective and that anti-mosquito measures should also be used. Travellers should be encouraged to continue chemoprophylaxis despite suffering what they believe to be a malarial illness. Many febrile episodes in long-term travellers or expatriates are incorrectly diagnosed as malaria.

Licensing restrictions
The specific problem relating to prophylaxis advice for long-term travellers is that long-term use of some of the currently advised malaria drugs falls outside the terms of their current Marketing Authorisation (License). Approaches in response to this time limit are:

- switching from one chemoprophylactic regimen to another as the time limit is reached
- discontinuing prophylaxis in favour of access to local advice and standby or physician-guided treatment
- continuing with one prophylactic regimen beyond its licensed length of use

General advice for all regimens
Once an individual is compliant on one prophylactic regimen and is tolerating it well, transfer to another regimen increases the likelihood of the development of side effects due to the introduction of a different drug.

There is no evidence of new side effects emerging during long-term use of any currently available prophylactics, though there may be risks associated with long-term use of chloroquine, see below.

Evidence for safety in long-term use comes more from an accumulating lack of evidence of harm than from scientific evidence of safety.
Individual risk assessments are important when deciding what advice should be given. In particular, advice on prophylaxis may be influenced by other measures that might be used by those staying in areas where the risk is seasonally variable.

Simplicity in regimen can, as always, be expected to improve compliance. The safest option is compliance with one of the most effective regimens.

Minimising exposure to infection is important, especially taking precautions against being bitten while asleep.

It is essential to seek medical advice promptly if symptoms develop.

ACMP advice on long-term use of specific antimalarials is summarised in Table 10.

### Specific considerations for women

See section on pregnancy and breastfeeding in Special groups (medical conditions), which includes advice on chemoprophylaxis prior to conception.

### Specific considerations for infants and older children

Refer to section Children, above.

Evidence in support of long-term use of antimalarials in infants and older children is limited. Advice for long-term use in these age groups is the same as for adults.

**Chloroquine**

Safe for both infants and young children.

**Proguanil**

Safe for use by infants and young children (119).

**Mefloquine**

Well tolerated (13). Long-term use of mefloquine is reported to be safe, well tolerated and not associated with an increase in adverse effects (121, 122, 123).

**Doxycycline**

Not for use in those under 12 years of age. No data available on the long-term use of doxycycline. However, long-term use of other tetracyclines for other indications is generally well tolerated (124).

**Atovaquone-proguanil combination preparation**

Both agents highly effective and safe (72).
Long-term visitors to the UK returning to live in malarious parts of the world

Persons returning to their original homes in malarious regions after prolonged residence in the UK are likely to have suffered a decline in the partial immunity to malaria that develops during childhood and is maintained by repeated exposure in endemic regions. They may therefore be at increased risk of suffering an acute attack of malaria after returning home.

Pregnant women and small children are at higher risk than others of suffering severe disease.

Risk assessment and personal counselling is essential to warn individuals of the risk of suffering from malaria, emphasising avoidance measures, and the need for immediate diagnosis and treatment of acute feverish illnesses.

Preventive measures appropriate to an endemic setting (125)

Bed nets
Bed nets and other personal barrier protective measures (for example, suitable clothing) are very low-cost, are effective long-term, have virtually no side-effects and will also help to protect from other mosquito-borne infections.

Intermittent Preventive Therapy (IPT)
If IPT is local policy in their destination country to prevent malaria in pregnancy and childhood, the returning visitor should be advised to seek medical advice on this immediately on arrival.

Case management of illness
People should be advised to seek medical attention immediately if either they or their children become feverish after repatriation in the endemic country. They should be warned that a malaria attack may be more serious because of diminished immunity.

Guidance
See the WHO and/or national country guidance on the appropriate measures in endemic settings which include IPT, insecticide-treated bed nets and case-management of illness with therapy.

Prophylaxis

Intended use
The ACMP prophylaxis guidance is for temporary protection for the UK traveller. This is not appropriate for individuals who are returning to permanent residence in their country of origin.

Exception for pregnant women and young children
A limited period of prophylaxis of 4 to 6 weeks for pregnant women and young children may be appropriate in some circumstances, to allow them to settle and arrange for future healthcare after arrival in the endemic country.
Standby treatment
Offering standby treatment is inappropriate where there are likely to be health services able to
diagnose and manage malaria.

Table 10. Long-term chemoprophylaxis for adults

<table>
<thead>
<tr>
<th>Malaria chemoprophylaxis</th>
<th>ACMP advice on long-term use</th>
</tr>
</thead>
</table>
| Chloroquine              | Considered safe for long-term use.\(^6\)  
Consider ophthalmic examination for retinopathy 6 to 12 monthly, 
commencing at 6 years’ cumulative prophylactic usage. |
| Proguanil                | Considered safe for long-term use. |
| Mefloquine               | No evidence of harm in long-term use if tolerated in the short term. 
Suggest can be used safely for up to 3 years in the absence of side 
effects. Longer term use possible if justified by the risk of exposure 
to malaria. The SmPC suggests that periodic checks on liver function 
and eye assessments should be taken if used for a prolonged period. 
Any person presenting with a visual disorder should be referred to 
their treating physician as this may require stopping 
chemoprophylaxis. |
| Doxycycline              | No evidence of harm in long-term use. Evidence suggests that it may 
be used safely for periods of at least up to 2 years. Longer term use 
possible if justified by the risk of exposure to malaria. |
| Atovaquone/Proguanil     | No evidence of harm in long-term use. Can be used confidently for 
travel up to one year. Longer term use possible if justified by the risk 
of exposure to malaria. |

Table 11. Half-lives of selected antimalarial drugs

<table>

\(^6\) Considered safe for long-term use but considerable concern regarding level of protective efficacy of the 
combination of chloroquine plus proguanil in certain geographical areas where the regimen used to be useful.
Frequently asked questions

Malaria prevention advice for travellers going on cruises

Cruises are a significant part of the holiday market. Most travellers on cruises are only ashore during daylight hours when the Anopheles vector of malaria is not feeding, and therefore do not require malaria chemoprophylaxis. Occasionally this is not the case and therefore the cruise itinerary must be reviewed to determine if there will be exposure to malaria.

For example, cruises along the East African coast may include a stop for a night or more in the port of Mombasa, Kenya and passengers may be ashore or on deck after dusk. These itineraries will require malaria chemoprophylaxis.

In addition, cruises that have an overnight stay in any other malaria endemic region of the world may require malaria chemoprophylaxis. Risks in specific destinations can be determined by referring to the country table in Chemoprophylaxis. Based on the destination, duration of exposure, and health of the traveller, the choice of malaria chemoprophylaxis can be made using the advice in these guidelines. All travellers on cruises should use insect bite avoidance measures (see Bite prevention).

‘Once you get malaria, it keeps coming back’ – true or false

Hypnozoite-induced relapses occur in vivax and ovale malaria but can be treated successfully and further relapses prevented. If the patient has received a full course of treatment with modern antimalarial drugs and has not been re-exposed to malaria, it is extremely unlikely that a history of recurrent febrile illness over a number of years is the result of chronic malaria.

Alternative antimalarial drugs which can be used for areas where chloroquine and proguanil are advised if they are unsuitable for a particular traveller

If a traveller is unable to take the combination of chloroquine plus proguanil, the alternative is a choice between one of 3 prescription drugs available: mefloquine, doxycycline or atovaquone/proguanil.

The choice of alternative depends on the reason why chloroquine and proguanil are not suitable (for example, those unable to take chloroquine due to epilepsy should not take mefloquine; if a traveller does not tolerate proguanil, then they should avoid atovaquone/proguanil as this also contains proguanil). For advice on malaria prevention in pregnant women there is a specific entry below.
Which antimalarial to give to a traveller with a history of psoriasis

Preguanil, atovaquone/proguanil, doxycycline and mefloquine do not cause problems in those with psoriasis. Chloroquine and chloroquine-related drugs can exacerbate psoriasis and should be avoided in those with generalised psoriasis or a history of such. Travellers with mild psoriasis can consider chloroquine if they are aware of the possible risks. The benefit of chemoprophylaxis with chloroquine may outweigh the risk of exacerbation of psoriasis, but each case should be considered on an individual basis.

Which antimalarial to give a traveller who is taking anticoagulants

The coumarins, including warfarin
Travellers should ensure their INR (International Normalised Ratio) is stable and within the therapeutic range prior to departure and they have adequate supplies of their anticoagulant for the whole trip.

Changes in diet and alcohol intake can affect the INR.

Patients on warfarin may have underlying cardiovascular disease and may be on cardiovascular medication. Interactions with other medication together with the individuals' medical history should be taken into account when deciding on appropriate malaria chemoprophylaxis:

Chloroquine
No interaction between warfarin and chloroquine documented in the BNF.

Proguanil
An isolated report of an enhanced effect of warfarin when taken together with proguanil (97).

Mefloquine
Not considered to be a problem for those taking warfarin. The manufacturer states that 'although no drug interaction is known with anticoagulants, effects of mefloquine on travellers should be checked before departure.' Please see below for how this can be monitored.

Doxycycline
The anticoagulant effect of coumarins (including warfarin) is possibly enhanced by tetracyclines (63).

Atovaquone/proguanil
Unknown whether there are interactions between atovaquone/proguanil and warfarin, although there have been isolated reports of an enhanced effect of warfarin when taken together with proguanil (see above under proguanil).

Advice for travellers needing malaria chemoprophylaxis who are taking warfarin
Travellers should inform their anticoagulant clinic and start taking their malaria tablets 2 to 3 weeks prior to their departure.
A baseline INR should be checked prior to starting chemoprophylaxis and re-checked after one week of taking chemoprophylaxis to determine whether the warfarin dosage needs to be adjusted. The traveller must check with their anticoagulant clinic to see if their INR is appropriate for travel. If a traveller is away for a long period of time the INR should be checked at intervals at the destination. However, the sensitivity of thromboplastin reagent used by some laboratories in different countries may vary (98). Self-monitoring of the INR may be suitable for some travellers, but must be under the supervision of an anticoagulant clinic, see Ringwald and others (99). INR self-testing devices are readily available and can be used safely by experienced patients. Expert patients, defined as such by their anticoagulant clinic, can undertake self-management. Other patients may perform INR self-testing and stay in contact with their home anticoagulant clinic for dosage recommendations (99). Given modern communication methods it should be possible to keep-in-touch from many malaria-endemic areas.

Once chemoprophylaxis has been completed, the INR should be checked again to re-stabilise anticoagulant therapy.

**Direct oral anticoagulants (DOAC)**

Dabigatran etexilate, rivaroxaban, apixaban and edoxaban are the most commonly available DOAC. They do not interact with food, do not require laboratory monitoring and have a lower potential for drug interactions than the coumarins (see below) (100).

There is relatively limited experience of antimalarial chemoprophylactic use those taking DOAC.

Apixaban and rivaroxaban are substrates of CYP3A4 and p-glycoprotein. Dabigatran is a substrate of p-glycoprotein.

Mefloquine inhibits CYP3A4 and p-glycoprotein, so could increase DOAC plasma concentrations which might lead to an increased bleeding tendency (100).

Atovaquone may produce minor inhibition of CYP3A4. The effect of proguanil on this enzyme is unknown.

Neither atovaquone nor proguanil inhibits p-glycoprotein (100).

In addition to following this guideline, please consult the drug interactions section of the latest edition of the BNF. If doubt exists after taking these steps, seek expert advice from a haematologist.

**How long a traveller can take different antimalarial drugs**

Guidelines for the long-term traveller are summarised in Special categories. Further detail is available in reference (126).
The main issues influencing the choice of malaria chemoprophylaxis on a long-term basis are the same as for short-term, that is adverse event profile, ease of compliance and efficacy. However, the specific issue relating to advice on chemoprophylaxis for the long-term traveller relates to current licensing restrictions. Long-term use of malaria chemoprophylaxis outside licensing restrictions is based on the cumulative evidence of lack of harm rather than positive evidence of safety. This situation is unlikely to change.

Chloroquine
Chloroquine has been taken safely for periods of many years at doses used for malaria chemoprophylaxis. However, there has been concern expressed about the possible development of retinal toxicity with long-term use of chloroquine (or hydroxychloroquine, often used to treat rheumatological disorders). Retinal toxicity has been described in those on daily chloroquine dosage for rheumatic disorders. As a result, 2 thresholds for the risk of retinopathy have been suggested, which are:

- a total cumulative dose of 100g of chloroquine base
- a daily dose of 250mg base (4mg/kg) (127)

The first threshold would require an adult to take chloroquine continuously, weekly, for a period of 6 years. The second threshold is far more than the prophylactic dosage. It has been concluded that the risk of retinopathy from prophylactic dosage alone is negligible (49). Further reassurance can be gained from the fact that retinopathy has only rarely been reported in patients taking weekly prophylactic dosages (127, 128).

ACMP advice suggests that chloroquine can be taken on a long-term basis. However, physicians should consider an ophthalmological examination every 6 to 12 months, beginning at 6 years' cumulative use for those on long-term chloroquine.

Proguanil
There is no time limit specified for the use of proguanil. Therefore, it can be taken continuously for several years.

Mefloquine
There are few data on the use of mefloquine for periods exceeding 2 years, although there is no evidence of cumulative toxicity, and mefloquine taken for over 1 year is well tolerated. The SmPC states the maximum recommended duration of administration of mefloquine is 12 months. However, advice from the ACMP indicates that there is no evidence of harm in long-term use if the drug is tolerated in the short term and suggests that mefloquine can be used safely for up to 3 years and beyond in the absence of significant side effects.

Doxycycline
The ACMP have concluded that there is no evidence of harm in long-term use of doxycycline and it may be taken safely for periods of at least up to 2 years and beyond in the absence of significant side effects. Longer term use possible if justified by the risk of exposure to malaria.
Atovaquone/proguanil
Both components of this combination preparation have been used individually on a long-term basis, although there is little experience of long-term use of the combination.

In a study of 154 travellers, 50% travelled for between 9 and 34 weeks with no excess of adverse effects and no appearance of unexpected adverse effects (129). The ACMP concludes that there is no evidence of harm in long-term use and suggests that it can be taken confidently for travel up to one year and beyond in the absence of significant side effects.

Antimalarial drugs which are suitable for women during pregnancy
Malaria during pregnancy is a serious illness for both the mother and the fetus. Pregnant women should be advised against travel to an area with malaria, particularly if there is chloroquine-resistant P. falciparum.

Results of animal studies indicate that tetracyclines cross the placenta, are found in fetal tissues and can have toxic effects on the developing fetus (often related to retardation of skeletal development). Evidence of embryotoxicity has also been noted in animals treated early in pregnancy (SmPC).

The UK National Teratology Information Service states that doxycycline is best avoided for antimalarial prophylaxis during pregnancy. However, if required before 15 weeks’ gestation it should not be withheld if other options are unsuitable. The course of doxycycline, including the 4 weeks after travel, must be completed before 15 weeks’ gestation.

The safety of atovaquone and proguanil hydrochloride when administered concurrently for use in human pregnancy has not been established and the potential risk is unknown. Animal studies showed no evidence for teratogenicity of the combination. The individual components have shown no adverse effects on parturition or pre- and post-natal development (SmPC).

ACMP advises against the use of atovaquone/proguanil for antimalarial chemoprophylaxis in pregnancy. However, if there are no other options, its use may be considered in the second and third trimesters after careful risk assessment. Folic acid 5mg daily is required for the length of time that proguanil is taken in pregnancy and also by those taking proguanil who are seeking to become pregnant. A registry-based study of the inadvertent use of atovaquone-proguanil in weeks 3 to 8 after conception identified 149 pregnancies and found no significant association between exposure to atovaquone-proguanil in early pregnancy and the risk of a major birth defect (79). An anonymous, internet-based survey to describe outcomes of pregnancies accidentally exposed to atovaquone-proguanil identified 10 who had atovaquone–proguanil exposure in the first trimester. All resulted in term births with no birth defects (92). Women should be reassured that taking atovaquone-proguanil combination preparation inadvertently prior to or during the first trimester is not an indication to terminate a pregnancy.
The data available from studies on the prophylactic use of mefloquine in pregnancy are generally reassuring. Mefloquine can be offered to pregnant women during the second and third trimesters and in the first trimester where travel to a high-risk area for *P. falciparum* is unavoidable. The risk of adverse effects of mefloquine use in pregnancy should be balanced against the risk of contracting malaria and the complications that can result. The decision on whether to recommend mefloquine should be carefully discussed with the traveller.

Women should be reassured that taking mefloquine inadvertently prior to or during the first trimester is not an indication to terminate a pregnancy. Both chloroquine and proguanil have been taken safely during pregnancy for many years although this combination offers insufficient protection in areas with chloroquine-resistant *P. falciparum*. Folic acid 5mg daily should be taken for at least the first trimester if proguanil is used in those who are pregnant and also by those taking proguanil who are seeking to become pregnant.

**Antimalarial drugs which can be taken by women breastfeeding**

Chloroquine plus proguanil can be used during breastfeeding. However, this combination provides suboptimal protection for the mother in areas of chloroquine-resistant *P. falciparum* malaria and should not be used except in the very rare areas where it is known to be effective. Although mefloquine is excreted in breast milk in small amounts experience suggests that it is safe to use in breast feeding.

The small amounts of antimalarials that pass into breast milk are not enough to protect the baby. Breastfeeding infants therefore need to take their own prophylaxis. If both mother and infant are taking mefloquine there is a possible concern that the amount of mefloquine the infant may receive will exceed the recommended maximum, particularly in infants in the lower weight range. However, this possible effect is likely to be short lasting as the weight of the child increases and the contribution of mefloquine in breast milk to the total prophylactic dose becomes relatively small.

Atovaquone/proguanil should generally be avoided in breast feeding, but ACMP advises that atovaquone/proguanil can be used when breast-feeding if there is no suitable alternative antimalarial.

The BNF states that tetracyclines should not be given to women who are breast feeding. Doxycycline is excreted in low concentrations in breast milk and is noted to be compatible with breast feeding by the American Academy of Pediatrics (64).

**Antimalarial drugs which can be given to babies and young children**

Both chloroquine and proguanil can be given from birth. Chloroquine is available as syrup but proguanil will need to be crushed and given with jam or food.
Mefloquine can be given to infants weighing 5kg or more (see summary of product characteristics). Atovaquone/proguanil can be given to infants weighing 5kg or more. Paediatric tablets are available.

Doxycycline is unsuitable for children under 12 years.

One of the main challenges in giving malaria tablets to babies and young children will be the practical aspects of administration.

All dosages for malaria chemoprophylaxis in children are found in Tables 4, 5 and 6, and in the British National Formulary for Children (BNFC). The dose for children will be dependent on the weight and age of the infant or child. Weight is a better guide than age.

Mosquito bite avoidance is extremely important for this age group.

The easiest way to calculate the correct dose of chloroquine for babies and young children

The dose steps for chloroquine syrup are not the same as for chloroquine tablets and a child may be prescribed a different dose of chloroquine depending on whether they take tablets or syrup (see Table 4 and Table 5). The main reason for any differences is due to the different amount of chloroquine base within the syrup and the tablets. The chloroquine syrup formulation contains 50mg chloroquine base/5mls syrup. The amount of chloroquine base contained within the tablets is 155mg.

The ACMP guidelines and BNFC dosages should be used.

While there is an optimum dose of chloroquine base for children of every weight, the final dosage given to the child will depend, in part, on the practicality of administering the formulation of chloroquine available (that is either tablet or syrup). For example, when dividing tablets for children, it is not possible to break a tablet into thirds, so the dosages will involve either a half or a quarter of a tablet.

The tables in Chemoprophylaxis have been calculated based on weight and surface area and the most accurate dose according to the weight is recommended. Although differences occur, all recommended dosages in the tables fall within accepted limits of toxicity. It is important not to overdose children with chloroquine as severe toxicity can occur.

A practical approach when calculating children's dosages for chloroquine is to decide on the most appropriate preparation (either tablet or syrup) for the child and calculate the dose appropriate to that preparation, according to Tables 4, 5 and 6.

Weight is a better guide than age for children, so they should be weighed for dosage calculation.
Advice for travellers travelling through areas where different antimalarials are recommended

Travellers planning extensive journeys across continents will often travel into areas which have different malaria chemoprophylaxis recommendations. In these situations, it is important that the traveller is protected in all areas of risk and the choice of medication needs to reflect the overall risk.

It may be possible to move from one regimen to another, although for shorter trips this may not be practical. For example, a traveller spending 2 weeks in an area where chloroquine plus proguanil may be recommended and then going for 6 weeks to an area where doxycycline or atovaquone/proguanil may be recommended would be advised to take either doxycycline or atovaquone/proguanil for the whole of the visit rather than change from chloroquine and proguanil to one of the other agents.

Antimalarial drugs for a traveller who has epilepsy

Both chloroquine and mefloquine are unsuitable for those with epilepsy. For areas with a high risk of chloroquine-resistant P. falciparum, doxycycline or atovaquone-proguanil can be used. However, for children under the age of 12 the only suitable antimalarial under these circumstances will be atovaquone-proguanil combination preparation.

Doxycycline half-life is reduced by phenytoin, carbamazepine, and barbiturates. Try to advise another antimalarial. If not possible or acceptable to the traveller, increase the dose of doxycycline to 100mg twice daily and counsel regarding measures to minimise the risk of adverse events.

Advice for a traveller with glucose 6-phosphate dehydrogenase deficiency

Glucose 6-phosphate dehydrogenase (G6PD) is an enzyme in the hexose monophosphate shunt of the glycolytic pathway. This shunt supports the red cell’s protection against oxidative damage. Absence of G6PD renders the red cell liable to haemolysis in the presence of some drugs.

The most common G6PD deficiency allele in Africa (G6PD A-) has been shown to confer some resistance to malaria in both hemizygous males and heterozygous females (101). Nevertheless, all G6PD-deficient travellers to malarious areas still require appropriate chemoprophylaxis.

Chloroquine

There is a theoretical risk of haemolysis in some G6PD-deficient individuals who receive chloroquine. This risk is acceptable in acute malaria (63) and G6PD levels are not usually checked before using chloroquine in treatment doses. Haemolysis does not appear to be a
problem when chloroquine is given in the dose recommended for malaria chemoprophylaxis, so there is no need to withhold chloroquine prophylaxis from those known to be G6PD-deficient.

Atovaquone-proguanil, doxycycline, mefloquine or proguanil prophylaxis
There is no need to withhold any of these agents from those known to be G6PD-deficient.

Primaquine
This drug is not currently recommended as a first line agent for malaria prevention in UK travellers, but may be considered in special circumstances on expert advice (48). There is a definite risk of haemolysis in G6PD-deficient individuals. The traveller’s G6PD level must be checked before primaquine is prescribed and G6PD deficiency contraindicates its use for prophylaxis.

Advice for people working on oil rigs
There are many staff employed in the oil industry predominantly based around West Africa. Employees commonly travel to these areas every 4 to 6 weeks, followed by a similar period of leave back in the UK. Oil rigs may be based in river estuaries or many miles offshore. Therefore, the level of risk may be difficult to assess until one period of work has been completed and antimalarial chemoprophylaxis should be taken for the whole of this first trip.

Antimalarial chemoprophylaxis is advised for those workers on oil rigs based in river estuaries. Offshore rigs pose little risk and antimalarial chemoprophylaxis may only be needed if staying overnight onshore during transit.

Advice for the traveller on a stopover
Many stopovers are in urban or tourist areas (particularly in Asia) and have minimal malaria risk. They are often situated in countries which may have malaria transmission in parts. Therefore, to assess risk it is essential to establish where overnight accommodation will be.

Stopovers in most of sub-Saharan Africa, including main cities, present a risk of malaria and antimalarial prophylaxis should be recommended. Stops to change or refuel aircraft do not usually require chemoprophylaxis, but it may be considered if the trip entails an overnight stop away from the airfield (assessed as above).

Doxycycline’s affect on oral contraception
Doxycycline is a non-enzyme-inducing antibiotic. The Faculty of Sexual and Reproductive Healthcare and the BNF advise that for combined oral contraceptives and for progestogen only oral contraceptives, additional precautions are not required when using non enzyme-inducing antibiotics. However, if the traveller suffers vomiting or diarrhoea, the usual additional precautions relating to these conditions should be observed.
Advice for travellers who discontinue chemoprophylaxis on or after return to the UK due to drug side-effects

Atovaquone-proguanil combination preparation
If atovaquone-proguanil is discontinued before completing 7 days’ dosage post-return, no additional prophylactic drug need be recommended but the traveller must be warned of the increased risk of malaria compared with those who take the full dosage regimen.

Increased vigilance is required and if the traveller becomes unwell in the first year after return, a blood test for malaria should be obtained without delay.

Suppressive prophylaxis (chloroquine, doxycycline, proguanil, mefloquine)
If suppressive prophylaxis is discontinued before completing 4 weeks’ dosage post-return, no additional prophylactic drug need be recommended, but the traveller must be warned of the increased risk of malaria compared with those who take the full dosage regimen. Increased vigilance is required and if the traveller becomes unwell in the first year after return, a blood test for malaria should be obtained without delay.

Appendices

Appendix 1a. Terms of reference 2022

Background

The Advisory Committee on Malaria Prevention (ACMP) was established in 1998 to formulate guidelines on malaria prevention in the UK. The guidelines are used by medical professionals and other travel medicine advisors based in the UK and many other countries. The guidelines are also the basis for recommendations from the National Travel Health Network and Centre (NaTHNaC). Today, the ACMP is overseen by UKHSA.

Purpose

To provide guidelines for health professionals on the prevention of malaria for travellers from the UK, updated annually or soon as there is a significant change in the distribution or behaviour of malaria, or the need to consider new advice on drugs and anti-insect measures. The Advisory Committee on Malaria Prevention will do this in light of data from the UKHSA Malaria Reference Laboratory, London (MRL), the Medicines and Healthcare Products Regulatory Agency (MHRA), World Health Organization Global Malaria Programme and other sources by:

- assessing new information on methods of malaria prevention for travellers, in relation to both efficacy and any unwanted effects
- reviewing patterns of malaria and of resistance to anti-malarial agents and anti-vector measures as determinants of malaria risk to travellers
- formulating practical advice on protection against malaria for UK travellers and making this available to those who advise travellers
- formulating advice on the treatment of malaria cases imported to the UK

Membership

Membership is open to medical and non-medical professionals who have expertise in:

- antimalarial drug resistance
- the use of antimalarial drugs
- malaria prevention and/or treatment methods
- the behaviour of UK travellers

The ACMP will be chaired by a leading international expert in malaria and tropical medicine or malaria and infectious diseases.

There are no strict restrictions on the number of members able to join the committee however; the number should be beneficial and not detrimental to the ACMP purpose. Membership will be
reviewed every 3 years, after which membership may be renewed. Members of sub-groups associated with the ACMP may not always be direct members of the ACMP.

**Accountability**

Individual ACMP members and associated sub-groups are responsible for reporting back on activities tasked to them, either directly to the committee or via the secretariat when necessary.

**Review process**

The Terms of Reference (ToR) will be reviewed annually by the ACMP committee and proposed changes will be mutually agreed prior to being finalised by the Chair. The relevance and value of any subgroups will be reviewed on a regular basis.

**Working methods**

Sub-groups will be convened as necessary to take forward different aspects of the work of the ACMP. Essential meeting papers will be electronically circulated to all members no later than 5 days prior to the next meeting whenever possible.

**Meeting arrangements**

Prevention Guidelines meeting will be held twice a year, face to face.

The Country Recommendations meeting and the Treatment Guidelines meeting will be held once a year, face to face.

Meetings will be chaired by the ACMP Chair. If the chair is not available, the deputy chair will take this role.

Non-ACMP members may be invited to meetings to contribute specialist skills, experience and knowledge when necessary.

A UKHSA scientific secretariat will coordinate and provide scientific secretariat support to the ACMP.

**Confidentiality or conflicts of interest**

Members of ACMP may have access to, see or hear information of a confidential nature with respect to the business of the ACMP and must not disclose such data to a third party unless expressly authorised to do so by the Chair. It is the individual responsibility of ACMP members to declare conflicts of interest annually, or when their conflicts of interest status changes, to the UKHSA scientific secretariat who will inform the committee.
Funding
ACMP is supported by the UK Health Security Agency.

Equality and diversity
The ACMP will treat all members equally with respect to the business of the committee and will encourage member diversity.

Appendix 1d. ACMP methodology

Purpose

To provide guidelines for health professionals on the prevention of malaria for travellers from the UK, updated annually or soon as there is a significant change in the distribution or behaviour of malaria, or the need to consider new advice on drugs and anti-insect measures.

Assessing in-country risk

The location, level of endemicity (parasite rate, entomological inoculation rate) and species of malaria parasites present are evaluated using data from:

- WHO Global Malaria Programme
- World Malaria Report
- estimates of the P. falciparum parasite rate and entomological inoculation rate published by the Oxford University Malaria Atlas project
- the number of cases and deaths in-country from published and unpublished sources
- Centers for Disease Control information for Central and South America, a region where the CDC has local knowledge
- local, expert contacts of the LSHTM Malaria Centre as necessary

Returned traveller data

The UKHSA Malaria Reference Laboratory, London (MRL) database captures 56% of cases (66% for P. falciparum) (130).

Numbers of cases are also converted to attack rates where good denominator data are available.

Details of the data requested on all imported malarias can be seen in the MRL case report form.

Enhanced surveillance of malaria cases from a country or region is undertaken following a major change in ACMP recommendations for travellers to that location.

Information on case numbers, species of parasite and special groups (for example, pregnant travellers) is sought.

Deaths are all subject to a detailed confidential audit.

MRL data on molecular markers of resistance to anti-malarial agents are reviewed.
Available preventive measures

New information on methods of malaria prevention for travellers, in relation to both efficacy and any unwanted effects is reviewed. Information on efficacy, adverse events and interactions with concomitant medication is reviewed for:

- bite prevention products using data from the published literature and the WHO Pesticide Evaluation Scheme (WHOPES)
- chemoprophylaxis and Standby Emergency Medication, using data from:
  - Medicines and Healthcare Products Regulatory Agency (MHRA) literature on chemoprophylaxis and stand-by treatment
  - efficacy and tolerance reports
  - specific drug trials
  - comparative studies
  - surveillance data and case/control studies
  - post-marketing surveillance
  - systematic reviews (Cochrane)
  - adherence and use

Other jurisdictions

Guidelines produced by WHO, CDC, Health Canada, Switzerland, Germany and Austria and Italy are compared with the conclusions reached by ACMP. The actual malaria situation in a particular country is the same whoever looks at it, yet published guidelines for malaria prevention written for travellers from non-endemic countries can and do differ (130). When malaria data are least good or limited, recommendations are extremely dependent on subjective expert opinion which results in different recommendations for chemoprophylaxis. This reflects the different health systems present in those countries, their experts’ tolerance of malaria risk versus the side-effect profile of antimalarial chemoprophylactic drugs and the medico-legal climate in which they practice.

Reaching a decision

These sources are assessed by the country recommendations sub-group then submitted for discussion and decision by the full ACMP as the basis for malaria prevention policy for each country. Data quality may not be uniform for the countries considered, so a single formula to decide policy is not possible and different weighting may need to be applied to the information sources used.

The future

Large-scale field diagnostics are likely to be widely used, especially in those countries moving to the pre-elimination phase of malaria eradication. Data generated both on species present and on drug-resistance markers, will give a much closer picture of the true in-country malaria situation and strengthen the evidence base for the ACMP guidelines.
Appendix 2. Template for risk assessment and summary of advice given

A risk assessment should be performed when an antimalarial is prescribed and this also applies to an over-the-counter sale of a Pharmacy only medicine. For the recently reclassified atovaquone plus proguanil product, the manufacturers provide a pharmacist checklist which can usefully be used as part of such an assessment. ACMP advises that a risk assessment for malaria chemoprophylaxis should be performed or checked by the pharmacist, is described specifically in the pharmacy standard operating procedures and a record be kept of the outcome of such an assessment. These principles should also apply to sales over the internet through registered e-pharmacies where an appropriate on-line risk assessment is conducted.

This template is suggested for use in gathering information required for risk assessment when advising on malaria prevention. It may be adapted for the particular circumstances of individual clinics.

NB. The information needed to complete this template and thus make a full risk assessment should be used in any consultation for malaria prevention, whether conducted face-to-face or via e-prescribing.

Guidance is available from the General Medical Council on remote prescribing.

⁷ First degree relatives are included in risk assessment as a precaution since risk of epilepsy and major depression is higher in first degree relatives of those in whom these conditions have been diagnosed. A condition in a first-degree relative may not contraindicate the use of an antimalarial but may influence the choice of drug.

Awareness of risk including bite prevention must still be recommended. Give advice to seek medical attention for any fever (up to about a year later).
Standby emergency medication

For the vast majority of travellers, standby emergency antimalarial medication is neither required nor recommended. Please undertake a risk assessment including information on the distance and time away from medical facilities which apply in each case.

Standby emergency medicine advised? Yes or no (please circle).

If standby emergency medication is recommended, please tick the regimen advised.

Standby emergency medication advice leaflet given? Yes or no (please circle).
Appendix 3. Emergency standby medication: traveller information leaflet

[Free to copy and paste for use]

You have been advised to carry emergency standby antimalarial medication with you on your forthcoming trip. This leaflet provides you with advice on when and how to use it. Please keep it safely with your medication. If you are travelling with a companion, please ask them to read this leaflet as they may be able to assist you in following its advice in the event of your becoming ill.

Incubation period of malaria

The minimum period between being bitten by an infected mosquito and developing symptoms of malaria is 8 days, so an illness with fever starting within the first week of your arrival in a malarious area is not likely to be due to malaria.

Symptoms and signs of malaria

Malaria usually begins with a fever. You may then feel cold, shivery, shaky and very sweaty. Headache, feeling sick and vomiting are common with malaria and you are also likely to experience aching muscles. Some people develop jaundice (yellowness of the whites of the eyes and the skin). It is not necessary for all these symptoms to be present before suspecting malaria as fever alone may be present at first.

When to take your emergency standby medication

If you develop a fever of 38°C/100°F or more, more than one week after being in a malarious area, seek medical attention straight away.

If you will not be able to get medical attention within 24 hours of your fever starting, start your standby medication and set off to find and consult a doctor.

How to take your emergency standby medication

First, take medication (usually paracetamol) to lower your fever. If your fever is controlled, it makes it less likely that you will vomit your antimalarial drugs then, without delay, take the first dose of your emergency standby antimalarial medication.

If you do vomit and it is within 30 minutes of taking the antimalarial drugs, repeat the first dose of them (but do not repeat the paracetamol). If you vomit 30 to 60 minutes after taking the first dose of the antimalarial drugs, repeat the treatment, but take only half the first dose.
Continue the treatment as instructed for the particular drugs prescribed for you. Please remember that this emergency standby medication has been prescribed based on your particular medical history and should be taken only by you as it may not be suitable for others.

Once you have completed your emergency standby medication you should restart your malaria prevention drugs one week after you took the first treatment dose of emergency standby medication. If your preventive medication consists of mefloquine and your standby treatment included quinine, you should wait at least 12 hours after completing the course of quinine before you restart mefloquine.

About the UK Health Security Agency

UKHSA is responsible for protecting every member of every community from the impact of infectious diseases, chemical, biological, radiological and nuclear incidents and other health threats. We provide intellectual, scientific and operational leadership at national and local level, as well as on the global stage, to make the nation health secure.

UKHSA is an executive agency, sponsored by the Department of Health and Social Care.
