Dioxins

Incident Management

Key Points

Fire

- non-flammable
- not soluble in water
- decomposes on heating to emit fumes of hydrogen chloride
- also decomposes when exposed to UV light

Health

- systemic toxicity may develop by all routes of exposure
- inhalation may cause irritation of the respiratory tract and dyspnoea
- nausea, vomiting, diarrhoea and abdominal pain may follow ingestion
- irritating to the skin and eyes
- exposure may cause headaches, dizziness, nausea, peripheral neuropathy and hepatic dysfunction
- chloracne may follow, it usually develops one to three weeks after exposure and typically resolves in a matter of weeks to months

Environment

- avoid release to the environment; inform the Environment Agency of substantial incidents where appropriate

<td>Systemic features</td>
<td>Headache, dizziness and nausea usually precede the development of chloracne (see below) and subside within one to two weeks.</td>
</tr>
<tr>
<td></td>
<td>Porphryia cutanea tarda (with hirsutism, increased skin fragility with blister formation following minor trauma, atrophic scarring, photosensitivity and hyperpigmentation) has also been described rarely in association with TCDD exposure as have severe myalgia, lethargy, anorexia, dyspepsia, nervousness, irritability, decreased libido and cold intolerance. Hyperkeratosis, lymphadenopathy, peripheral neuropathy with sensory impairment and lower extremity weakness, dystonia and tremor are recognised. Hepatic dysfunction, manifest as increased transaminase activities, a prolonged prothrombin time, hypercholesterolaemia, hypertriglyceridaemia and pancreatitis have been observed</td>
</tr>
<tr>
<td>Delayed effects</td>
<td>Hepatic dysfunction or raised transaminase activities may appear late or persist after acute exposure</td>
</tr>
<tr>
<td></td>
<td>Chloracne (pale yellow cysts resembling acne vulgaris) is the most characteristic manifestation of TCDD exposure and develops typically one to three weeks after exposure, although may be delayed for several weeks. Lesions occur typically on the malar, temporal, periorbital and pre- and postauricular areas. Severe chloracne may involve the trunk, arms, legs, face, neck and back. Mild cases may resolve in weeks or months. More severe cases can persist for years</td>
</tr>

</table>

Reference
Decontamination at the Scene

Summary
The approach used for decontamination at the scene will depend upon the incident, location of the casualties and the chemicals involved. Therefore, a risk assessment should be conducted to decide on the most appropriate method of decontamination.

Following disrobe, improvised dry decontamination should be considered for an incident involving dioxins, unless casualties are demonstrating signs or symptoms of exposure to caustic or corrosive substances.

Emergency services and public health professionals can obtain further advice from Public Health England (Centre for Radiation, Chemical and Environmental Hazards) using the 24 hour chemical hotline number: 0344 892 0555.

Disrobe
The disrobe process is highly effective at reducing exposure to HAZMAT/CBRN material when performed within 15 minutes of exposure.

Therefore, disrobe must be considered the primary action following evacuation from a contaminated area.

Where possible, disrobe at the scene should be conducted by the casualty themselves and should be systematic to avoid transferring any contamination from clothing to the skin. Consideration should be given to ensuring the welfare and dignity of casualties as far as possible.

Improvised decontamination
Improvised decontamination is an immediate method of decontamination prior to the use of specialised resources. This should be performed on all contaminated casualties, unless medical advice is received to the contrary. Improvised dry decontamination should be considered for an incident involving chemicals unless the agent appears to be corrosive or caustic.

Improvised dry decontamination
- any available dry absorbent material can be used such as kitchen towel, paper tissues (eg blue roll) and clean cloth
- exposed skin surfaces should be blotted and rubbed, starting with the face, head and neck and moving down and away from the body
- rubbing and blotting should not be too aggressive, or it could drive contamination further into the skin
- All waste material arising from decontamination should be left in situ, and ideally bagged, for disposal at a later stage.

**Improvised wet decontamination**
- Water should only be used for decontamination where casualty signs and symptoms are consistent with exposure to caustic or corrosive substances such as acids or alkalis.
- Wet decontamination may be performed using any available source of water such as taps, showers, fixed installation hose-reels and sprinklers.
- When using water, it is important to try and limit the duration of decontamination to between 45 and 90 seconds and, ideally, to use a washing aid such as cloth or sponge.
- Improvised decontamination should not involve overly aggressive methods to remove contamination as this could drive the contamination further into the skin.
- Where appropriate, seek professional advice on how to dispose of contaminated water and prevent run-off going into the water system.

**Additional notes**
- Following improvised decontamination, remain cautious and observe for signs and symptoms in the decontaminated person and in unprotected staff.
- If water is used to decontaminate casualties this may be contaminated, and therefore hazardous, and a potential source of further contamination spread.
- All materials (paper tissues etc) used in this process may also be contaminated and, where possible, should not be used on new casualties.
- The risk from hypothermia should be considered when disrobe and any form of wet decontamination is carried out.
- People who are contaminated should not eat, drink or smoke before or during the decontamination process and should avoid touching their face.
- Consideration should be given to ensuring the welfare and dignity of casualties as far as possible. Immediately after decontamination the opportunity should be provided to dry and dress in clean robes/clothes.

**Interim wet decontamination**
Interim decontamination is the use of standard fire and rescue service (FRS) equipment to provide a planned and structured decontamination process prior to the availability of purpose-designed decontamination equipment.

**Decontamination at the scene references**
Clinical Decontamination and First Aid

Clinical decontamination is the process where trained healthcare professionals using purpose-designed decontamination equipment treat contaminated people individually.

Detailed information on clinical management can be found on TOXBASE – www.toxbase.org.

Important note
- once body surface contaminants have been removed or if your patient was exposed by ingestion or inhalation the risk that secondary care givers may become contaminated is very low. Secondary carers should wear standard hospital PPE as a precaution against secondary contamination from vomit and body fluids
- if the patient has not been decontaminated following surface contamination, secondary carers must wear appropriate NHS PPE for chemical exposure to avoid contaminating themselves. The area should be well ventilated

Clinical decontamination following surface contamination
- carry out decontamination after resuscitation
- this should be performed in a well-ventilated area preferably with its own ventilation system
- contaminated clothing should be removed, double-bagged, sealed and stored safely
- decontaminate open wounds first and avoid contamination of unexposed skin
- any particulate matter adherent to the skin should be removed and the patient washed with soap and water under low pressure for at least 10 – 15 minutes
- pay particular attention to mucous membranes, moist areas such as skin folds, fingernails and ears

Dermal exposure
- decontaminate (as above) the patient following surface contamination
- if systemic features are present, treat as per inhalation\ingestion
- other supportive measures as indicated by the patient’s clinical condition

Ocular exposure
- remove contact lenses if present
- anaesthetise the eye with a topical local anaesthetic (eg oxybuprocaine, amethocaine or similar); however, do not delay irrigation if local anaesthetic is not immediately available
• immediately irrigate the affected eye thoroughly with 1,000 mL 0.9% saline or equivalent crystalloid (for example via an infusion bag with a giving set) for a minimum of 10 – 15 minutes irrespective of the initial conjunctival pH. A Morgan Lens may be used if anaesthetic has been given.

• any particles lodged in the conjunctival recesses should be removed

• repeated instillation of local anaesthetics may reduce discomfort and help more thorough decontamination; however, prolonged use of concentrated local anaesthetics is damaging to the cornea

• patients with corneal damage and those whose symptoms do not resolve rapidly should be referred urgently to an ophthalmologist

• other supportive measures as indicated by the patient’s clinical condition

• if systemic features are present, treat as per inhalation/ingestion

Inhalation/Ingestion

• maintain a clear airway and ensure adequate ventilation

• administer supplemental oxygen as required

• other supportive measures as indicated by the patient’s condition
