This report is published monthly on the PHE website. For further information on the surveillance system mentioned in this report, please visit the Hospital Norovirus Outbreak Reporting System website.

Contents: | Summary | Reporting caveats | Hospital Norovirus Outbreak Reporting System | Laboratory reporting | Laboratory surveillance update | Activity in prisons | Rotavirus | Acknowledgements | References

## Summary

This is the last monthly report; the first weekly report will be published on 18 October 2018.

For national surveillance to be effective, it is essential that laboratories refer representative proportions of positive norovirus and rotavirus samples from gastroenteritis outbreaks to the national reference laboratory (Enteric Virus Unit, PHE Colindale). For hospital outbreaks of suspected or confirmed norovirus, please also ensure these are reported to the Hospital Norovirus Outbreak Reporting System (HNORS) - [http://bioinformatics.phe.org.uk/noroOBK/home.php](http://bioinformatics.phe.org.uk/noroOBK/home.php).

### Norovirus – routine laboratory reporting (SGSS)

- Since week 27, 2018 there have been 722 laboratory reports of norovirus in England and Wales. Although this is higher than the average number for the same period in the previous 5 seasons from season 2013/14 to season 2017/18 (633), the number of laboratory reports in the early part of each season is low and therefore the percentage difference may fluctuate.

### Norovirus – Hospital Norovirus Outbreak Reporting System (HNORS)

- Reports of suspected and confirmed outbreaks of norovirus in hospitals in England for weeks 36 to 39, 2018 are currently at lower levels than in previous years (2012-2017).

### Rotavirus – routine laboratory reporting (SGSS)

- Since week 27, 2018, there have been 458 laboratory reports of rotavirus in England and Wales. This is 17 per cent lower than the average for 2013/14 to 2017/18 (552) (the period after vaccine was introduced).

- Following the introduction of the rotavirus vaccine into the routine childhood immunisation schedule in July 2013, the total number of laboratory-confirmed rotavirus infections each season has remained low compared to the pre-vaccine period.
Reporting caveats

Data sources

- Outbreaks of norovirus in hospitals are derived from the Hospital norovirus outbreak reporting system (HNORS).

- Frontline laboratory reports of positive norovirus and rotavirus samples are provided by the Second Generation Surveillance System (SGSS).

- Reports of outbreaks of diarrhoea and vomiting in prisons and other places of detention are provided by the Health and Justice Team, Public Health England.

- Norovirus genotype and GII.4 strain characterisation and other virology data are provided by the Virus Reference Department (VRD) from a national sentinel norovirus typing surveillance programme.

Interpretation of trends

- In order to capture the winter peak of activity in one season, for reporting purposes, the norovirus and rotavirus season runs from week 27 in year 1 to week 26 in year 2, i.e. week 27 2016 to week 26 2017, July to June.

- Norovirus activity varies from season-to-season; therefore it is most appropriate to use the 5 season average for comparison with the current season. Due to this variability between norovirus seasons, it is not possible to predict how the current season will progress.

- Norovirus is predominantly a winter pathogen; however, norovirus infections occur in the summer months.

- Data included in this report are provisional and are extracted from live reporting systems therefore numbers may fluctuate. Laboratory testing and reporting practices are known to vary. Data from laboratory reporting and HNORS are subject to a reporting delay and the number reported in the most recent weeks is likely to rise further as laboratory reports are received. Due to these reporting delays, data pertaining to the most recent two weeks are not included.

Hospital Norovirus Outbreak Reporting System (HNORS)

- Hospital norovirus outbreak reporting scheme (HNORS) data are for England only. Reporting to HNORS is voluntary and variations may reflect differences in ascertainment or reporting differences by region.

- Not all outbreaks reported to HNORS result in whole ward closure, some closures are restricted to bays only.

- It is important to note that not all suspected cases are tested for norovirus. Where there is an outbreak, a sample of individuals will be tested.

Frontline laboratory reporting (SGSS)

- Laboratory data are for England and Wales, as reported to Public Health England by laboratories in England and Wales, and are specimens taken from faeces and the lower gastrointestinal tract only. Reporting may be subject to differences in regional ascertainment. Reporting region is based on patient’s area of residence.

- Most laboratory tests in use do not distinguish vaccine from wild-type rotavirus. In the post-vaccine period, further characterisation of laboratory-confirmed rotavirus infections and considering broader testing of cases among eligible infants for other enteric pathogens are increasingly important to avoid over-attributing rotavirus as a cause of diarrhoea in young children.
• For rotavirus, comparison is made with the 10 season period 2003/04 to 2012/13 prior to the vaccine introduction and the 4 season period 2013/14 to 2016/17 post vaccine introduction.

**Norovirus genotype and GII.4 strain characterisation (VRD data)**

• Virus genotype and GII.4 strain characterisation data from the reference laboratory are subject to a reporting delay, and the numbers reported in any week may rise further as specimens are referred and additional characterisation data become available.

---

**Hospital Norovirus Outbreak Reporting System (HNORS) and laboratory reports (SGSS)-England**

In weeks 36, 2018 to 39, 2018 (03/09/2018 to 30/09/2018 inclusive) the hospital norovirus outbreak reporting system (HNORS) recorded two outbreaks of suspected or confirmed norovirus in England, both of which led to ward/bay closures or restrictions to admissions and one of which (50 per cent) was laboratory confirmed as a norovirus outbreak.

Reports of suspected and confirmed outbreaks of norovirus in hospitals in England are currently at lower levels than in previous years (2012-2017).

This season (since week 27, 2017) there have been 19 outbreaks reported, 17 of which (89 per cent) resulted in ward/bay closures and 15 (79 per cent) of which were laboratory confirmed as norovirus.

**Norovirus Laboratory Reporting (SGSS) - England and Wales**

The number of laboratory reports of norovirus in England and Wales, as reported to Public Health England, in this season (week 27, 2018 to week 39, 2018) is 722.

Although this is 14 per cent higher than the average number for the same period in the previous 5 seasons from season 2013/14 to season 2017/18 (633), the number of laboratory reports in the early part of each season is low and therefore the percentage difference may fluctuate. Norovirus activity varies from season to season and no two seasons are the same. The emergence of novel strains of norovirus may result in shifts in seasonality (Allen et al, 2014).
Figure 1: Seasonal comparison of laboratory reports of norovirus 2010/11-2018/19 (England and Wales)

Figure 2: Laboratory (England and Wales) and hospital outbreak reports (England) by week of occurrence 2018/19 compared to five season average (2013/14-2017/18)
Figure 3: Cumulative number of laboratory reports of norovirus by season 2010/11-2018/19 (England and Wales)

Figure 4: Laboratory reports of norovirus by week 2009-2018 (England and Wales)
Noroviruses of the genocluster genogroup II-genotype 4 (GII.4) are the most commonly detected, accounting for 62.2% of typed samples in England and Wales. In 2018 viruses belonging to the GII.4 genocluster have been the most frequently detected in England and Wales. Noroviruses of the GII.4 genocluster are the most commonly detected norovirus genotype worldwide.

The Virus Reference Department monitors the genetic diversity of noroviruses belonging to the dominant GII.4 genotype that circulate in England and Wales. Since 2001, there have been five major GII.4 strains circulating in England and Wales (and worldwide), which have successively replaced one another. Replacement events are associated with antigenic drift in the virus (Allen et al 2008, 2009, Zakikhany et al 2012). Since the winter of 2012/13, the GII.4 strain Norovirus/GII.4/Sydney/2012 has been dominant worldwide, including in England and Wales (Allen, Adams, et al 2014).
Activity in prisons and other places of detention (Health and Justice Team) - England

Three outbreaks of diarrhoea and vomiting were reported in prisons between weeks 36, 2018 and 39, 2018.

For guidance on the management of outbreaks in prisons see:

Rotavirus Laboratory Reporting (SGSS) - England and Wales

The number of laboratory reports of rotavirus in England and Wales as reported to Public Health England, in this season (week 27, 2018 to week 39, 2018) is 458. This is 17 per cent lower than the five season average (post-vaccine) for the same period in the seasons 2013/14 to 2017/18 (552).

Rotavirus particularly contributes to reported diarrhoea and vomiting illness in children aged under five however in the first season following the introduction of the rotavirus vaccine in July 2013, a 77 per cent decline in laboratory-confirmed rotavirus infections in infants was observed (Atchison et al, 2016). The total number of laboratory-confirmed rotavirus infections each season has since remained low compared to the pre-vaccine period.

Acknowledgements

This report was prepared by the Gastrointestinal Infections Department, Centre for Infectious Disease Surveillance and Control, Public Health England. We are grateful to all who provided data for this report including infection control staff in hospitals who take the time to contribute data to HNORS, the Virus Reference Department, Public Health England and the Health and Justice Team, Public Health England.

Any queries or comments can be directed to noroOBK@phe.gov.uk
