328.1 billion miles were driven on Great Britain’s roads in 2018, similar (0.3% increase) to the previous year

Vehicle miles travelled by selected vehicle types in Great Britain, 2008-2018

In 2018:

• **Car traffic** remained broadly stable (increasing by 0.2%) compared to 2017. The figure of 255.0 billion vehicle miles (bvm) is the highest annual estimate ever of car traffic (page 5).

• **Van traffic** grew slightly (by 0.9%) from 2017 to 51.0 bvm. There has been a slowdown in the growth of van traffic over the last two years. (page 7).

• **Lorry traffic** remained broadly stable (increasing by 0.3%) compared to 2017 (page 9).

• **Pedal cycle traffic** (cyclists on public highways, and the cycle paths and footpaths adjacent to them) was 3.3 bvm, 17.2% above the figure ten years before (page 14).

• **Motorways** carried 69.0 bvm of traffic, broadly stable (0.5% increase) compared to 2017, and 10.9% more than ten years ago (page 18).

• **The Strategic Road Network** carried 94.7 bvm of traffic (a new high); one-third of all motorised traffic in England (page 22).

• ‘A’ roads saw a 1.4% rise in traffic from 2017 (page 17).

• **Minor road traffic** decreased 1.3% since 2017 (page 17).
Summary statistics

Breakdown of traffic in Great Britain 2018, by vehicle type and road type

Bubble area is proportional to vehicle miles travelled (units = billion vehicle miles)

Key definitions:
Traffic
Traffic refers to the total distance travelled by all vehicles over the year, measured in vehicle miles. This combines the number of vehicles on the road, and how far they drive.

Flow
Flow refers to the average number of vehicles travelling along a given stretch of the road network per day (24 hours).

Billion
In this release 1 billion = 1000 million (10^9).

Index Number
Used in this release to compare changes over time (from a selected base year) across multiple indicators where they cannot be directly compared.

The summary table below shows patterns in vehicle traffic across a range of years.

</tbody>
</table>
Since 1949 motor vehicle traffic has increased more than ten-fold from 28.9 to 328.1 billion vehicle miles, largely driven by steady growth in car traffic.

The level of traffic growth since 1949 has varied by vehicle type. Car traffic in 2018 was around 20 times higher, whereas lorry traffic was only around twice as high and bus traffic was similar to the 1949 level. This has altered the share of traffic by vehicle type over time, with the car traffic share rising from 44% in 1949 to 78% in 2018, and the lorry traffic share falling from 27% to 5%.

Traffic growth from year to year has not been constant, being punctuated by short periods of stasis or decrease due to various factors (discussed in the section ‘Factors affecting traffic’).

In contrast to motor vehicle traffic, pedal cycle traffic (on public highways, and the cycle paths and footpaths adjacent to them) fell rapidly during the 1950s and 1960s, followed by a period of relative stability. Since 2000, there has been a steady rise to 3.3 billion cycle miles in 2018. Cycling levels in 2018 were 34% higher than in 1993.
This section breaks down the latest traffic and longer term trends in traffic by vehicle type.

In the 25 years between 1993 and 2018:

- **Van traffic** has seen the fastest growth (in percentage terms) of any motor vehicle, almost doubling to reach a record high of 51.0 billion vehicle miles. In the last two few years there has been a slowdown in growth, with the latest year-on-year change increasing by 0.9%.

- Distance travelled by **cars and taxis** increased by 21.4% to 255.0 billion vehicle miles. This figure is a new record high.

- **Lorry** traffic increased by 13.3% to 17.1 billion vehicle miles. Lorry traffic still remains below the peak seen in the mid 2000's

- **Bus and coach traffic** saw the largest decrease of any vehicle type, falling by 20.0% to 2.3 billion vehicle miles.

- **Motorcycle** traffic increased by 17.0%, however the latest year traffic (2.7 billion vehicle miles) is below the peak seen in 2003 by 21%.

**Cars and taxis remain the dominant vehicle type:**

Since 1993, cars have accounted for around four-fifths of all motor vehicle traffic and continue to be the main contributor to changes in overall motor vehicle traffic.

However, vans have become more important over the last 25 years, accounting for 16% of all motor vehicle traffic in 2018 compared to 10% in 1993.
Compared with 2017, car and taxi traffic in Great Britain remained broadly stable (increasing by 0.2%) at 255.0 billion vehicle miles in 2018.

Car traffic increased on all ‘A’ road types between 2017 and 2018. Car traffic levels on minor roads were down from the previous year.

The fastest growth in car traffic (in percentage terms) over the last ten years has occurred on rural ‘A’ roads, whereas there has been little change in car traffic on urban roads during this period.

Over the longer term, car traffic has shown the most marked increase on motorways, rising by 55% between 1993 and 2018, and showing only a small and brief dip during the 2008 recession.

The distribution of car miles travelled across the different road types was relatively even compared to the distribution of lorries which are less prevalent on minor roads.
Trends in car use
Different trends in car traffic have been seen before and after 2013.

Between 2002 and 2013, changes in car traffic reflected a balance between a rise in population and a falling average personal car/van driver distance, as reported by the National Travel Survey (NTS).

Over the same period, car stock rose rapidly; more quickly than car traffic. Household car/van ownership rates showed little change, but the number of households grew by 10%, driving the growth in vehicle numbers.

Taken together this suggests that, while personal access to cars remained similar between 2002 and 2013, people drove their cars fewer miles. Dividing car traffic by the number of cars suggests that annual mileage per car fell from around 9,400 miles to 8,200 over this period.

See pages 31-32 and the further information sidebar below for possible drivers of these trends.

Personal car travel, car stock and car traffic in Great Britain, 2002-2018*

Between 2013 and 2018, growth in car traffic outstripped population growth, indicating an increase in average car driver distance (car traffic per capita grew by 2.9% in this time period). Recent estimates from the NTS show a similar pattern. Whether or not this continued into 2018 will be seen when NTS statistics for 2018 are published later in 2019.

In contrast, car traffic and car stock grew at similar rates between 2013 and 2018. Leading to the previously seen fall in mileage per car to slow down (by -1.7% in the five years since 2013). This period saw a marked fall in fuel retail prices (of 9 and 10 pence per litre for petrol and diesel respectively), which may have influenced how often or how far car owners travelled by car.

Sources and further information
Figures on car stocks are sourced from Vehicles Statistics, personal travel from the National Travel Survey, population from the Office for National Statistics, fuel price data from the Department for Energy and Climate Change and household numbers from the Ministry of Housing, Communities & Local Government. Further discussion of factors influencing trends in travel can be found in the DfT reports ‘Understanding the drivers of road travel’ and ‘Road use statistics’.

*Latest data for average personal car/van driver distance only to 2017

Between 2013 and 2018, growth in car traffic outstripped population growth, indicating an increase in average car driver distance (car traffic per capita grew by 2.9% in this time period). Recent estimates from the NTS show a similar pattern. Whether or not this continued into 2018 will be seen when NTS statistics for 2018 are published later in 2019.

In contrast, car traffic and car stock grew at similar rates between 2013 and 2018. Leading to the previously seen fall in mileage per car to slow down (by -1.7% in the five years since 2013). This period saw a marked fall in fuel retail prices (of 9 and 10 pence per litre for petrol and diesel respectively), which may have influenced how often or how far car owners travelled by car.

Sources and further information
Figures on car stocks are sourced from Vehicles Statistics, personal travel from the National Travel Survey, population from the Office for National Statistics, fuel price data from the Department for Energy and Climate Change and household numbers from the Ministry of Housing, Communities & Local Government. Further discussion of factors influencing trends in travel can be found in the DfT reports ‘Understanding the drivers of road travel’ and ‘Road use statistics’.
Van traffic grew 0.9% between 2017 and 2018 to reach a record high of 51.0 billion vehicle miles; the fastest growth in percentage terms of any motor vehicle type.

Van traffic rose to new record highs on all road types except urban roads between 2017 and 2018. Motorways and rural ‘A’ roads carried over half of all van traffic in 2018.

The rapid rise in van traffic over the last 25 years means that van traffic now makes up around 16% of total traffic, compared to 10% in 1993.

**Why is van traffic rising so quickly?**

Alongside the 89% increase in van miles between 1994 and 2018, the number of licensed vans rose 88% over the same period, from 2.1 to 4.0 million.

In contrast to the trend seen in average car mileage, the average annual mileage per van in Great Britain (estimated from van vehicle miles divided by van stock) has remained stable, at around 13,000 miles per year.
Over the last twenty years, trends in van traffic have followed changes in the economy closely. This is perhaps to be expected given the mainly commercial use of vans, and the variety of uses to which they are put*.

Gross domestic product (GDP) resumed growth after the 2008 recession, but van traffic grew even faster than GDP between 2012 and 2018. This additional growth may be linked to a shift in the way consumers and businesses operate.

Drivers of this rapid growth could include:

- Growth in internet shopping and home deliveries. In 2018, 78% of adults shopped online at least once compared to 53% in 2008.

- Changes to company car taxation rules and vehicle excise duty in the early-to-mid 2000s, which may have made vans a cheaper alternative and so caused people to switch to vans from cars.

- Less strict regulation on driver training, driver’s hours restrictions and roadworthiness testing for vans than for lorries, making it easier to find drivers for vans. This may encourage businesses to substitute vans for small lorries.

Van Definition

Light Commercial Vehicle (LCV; a.k.a. van) Goods vehicles not exceeding 3.5 tonnes gross vehicle weight

Survey into Light Commercial Vehicles

In 2019, the department commissioned a project to conduct research into the light commercial vehicle sector. The aim of this research is to provide robust and timely evidence of LCV travel activity and behaviours. Findings will be published in next years road traffic estimates publication.

* The most recent survey was undertaken in 2008, a postal survey of UK registered vans, to find out who owned vans, what they were used for, and how far they were driven. The DfT report can be found here.

Sources and further information

Gross Domestic Product and Internet usage data are sourced from the Office for National Statistics.
In 2018 lorries travelled 17.1 billion vehicle miles, remaining broadly stable (increasing slightly by 0.3%) compared with 2017.

Lorry traffic remained broadly stable (increasing slightly by 0.3%) between 2017 and 2018. Lorry traffic increased on motorways and rural ‘A’ roads in 2018, with decreases seen on all other road types, continuing the general trend in recent years. Lorry traffic on motorways reached a new peak in 2018, of 8.0 billion vehicle miles. Motorways carry 47% of all lorry traffic in Great Britain; together, motorways and rural ‘A’ roads carry 84% of lorry traffic.

Factors affecting trends in Lorry traffic

In recent years, lorry traffic appears to be closely correlated with changes in the economy. This can be seen in general terms by comparing the index of Gross Domestic Product (GDP) with lorry traffic (right). Both GDP and lorry traffic fell sharply during the 2008 recession, and have grown sharply since 2012.
**Longer term trends**

A key factor in understanding trends in lorry traffic over the longer term is that lorries comprise of a wide range of differently sized vehicles, able to carry differing quantities of goods.

Between 1993 and 2018 trends in lorry traffic differed markedly between different vehicle sizes. Traffic of lorries with four or more axles was 87% higher in 2018 than 25 years ago, whereas for lorries with less than four axles it had fallen by 27.5%.

The statistics from DfT’s annual freight survey show a similar trend, presenting freight transport by gross vehicle weight. Between 1993 and 2018, heavier lorries (weighing >33 tonnes) moved an increasing proportion of goods by road (77% in 2018 compared to 58% in 1993).

As a result, road freight in lorries is now more concentrated in heavier lorries than in the past, and fewer vehicle miles are being driven to transport the same weight of goods.

It could also partly explain the different trends in lorry traffic by road types. Freight is likely moved more efficiently by larger lorries on major roads, than on narrow or busy minor and urban roads. It is also possible that vans are being used to perform work previously carried out by smaller lorries.

**Lorry Definition**

Heavy Goods Vehicle (HGV; a.k.a. lorry) Goods vehicles over 3.5 tonnes gross vehicle weight, including both articulated and rigid body types.

**Goods lifted and goods moved**

Goods lifted refers to the total weight of freight transported in a load, measured in tonnes. 
Goods moved is defined as the weight of goods in each load multiplied by the distance the load is transported, measured in tonne miles or tonne kilometres.

**Data Source**

The figures for HGV activity on this page come from DfT’s Continuing Survey of Road Goods Transport (CSRGT) for British registered HGVs. It provides information on weight of goods lifted and moved by vehicle type and commodity type.
Motorcycles and scooter traffic fell by 0.9% in 2018 compared to the previous year. Motorcycle traffic has declined over the last ten years, from a peak in the mid-2000s.

Motorcycle and scooter traffic trends have fluctuated across the different road types in recent years. Rural ‘A’ roads have seen a 8% increase over the last five years, in contrast to a decrease on motorways and stability on urban ‘A’ roads.

Results from the National Travel Survey (NTS) indicate that the average distance ridden per motorcyclist in England has been fairly stable over the last decade, although it has had year-to-year variability.

However, there was a downward trend in the proportion of households having access to a motorbike over the period, dropping from 3% in 2002 to 2.5% in 2017.

In other words, the distance ridden by those who ride has changed little, but it appears that fewer people are riding motorbikes.
Buses & coaches

Bus and coach traffic fell by 4.7% between 2017 and 2018 - the largest decrease of any vehicle type. This is similar to the trend seen in recent years.

2.3 billion bus miles in 2018

0.7% of motor vehicle traffic

-4.7% from 2017
-20.0% from 1993

Index of bus & coach miles, by road type (1993 = 100)

Local bus mileage and passenger mileage

Changes in local bus services have a strong influence on the overall trend in bus and coach traffic, because local bus service mileage makes up a large proportion of the total (approximately 60%). DfT bus statistics show that between 1999/00 and 2017/18, mileage of local bus services in Great Britain fell by around 12%. However, over the same period bus passenger miles rose by nearly one-quarter, from 13.9 billion in 1999/00 to 16.9 billion in 2017/18.

The difference in trend between vehicle mileage and passenger mileage reflects an increase in the average number of passengers travelling on each bus, from 8.4 passengers per bus in 1999/00 to 11.5 passengers per bus in 2017/18.

The large number of passengers per bus (in comparison to occupancy of cars, motorcycles and pedal cycles) means that, although bus and coach vehicle mileage is a similar level as motorcycle and pedal cycles miles, it accounts for an order of magnitude more trips by people.

Local bus vehicle mileage and passenger mileage, Great Britain 1999/00 - 2017/18

Source: DfT bus statistics
Long term trends: by road type

The majority (59%) of bus and coach miles in Great Britain are driven on urban roads, near to densely populated areas. This road type has, however, seen large decreases in bus traffic over the last decade.

Since 2008, bus traffic has fallen 45% and 35% on rural and urban minor roads respectively. Bus traffic on rural and urban ‘A’ roads has also fallen over the same period but by a lesser amount (13% and 16% respectively).

The fall observed in bus and coach mileage over the last decade may partly be explained by the trends in local bus service mileage.

Local bus mileage in Great Britain fell 11% in the ten years since 2007/08. This was due to a decrease of 46% in local authority supported bus mileage in Great Britain outside London over the same period.

Increases in commercial bus mileage since 2010 have partially offset the decline in supported mileage, but these services may be more likely to use ‘A’ roads, causing a shift in mileage from minor to ‘A’ roads.

Long term trends: by location

Local bus services mileage trends since 1999/00 have not been consistent across the country.

Local bus mileage in London rose rapidly until 2004/5, since when it has increased more slowly.

In the rest of Great Britain local bus mileage has seen an overall downward trend since 1999/00. The declines in Scotland and Wales have not been smooth, falling more rapidly since 2010.
Pedal cycles travelled 3.3 billion miles on roads* in 2018, 1.8% further than in the previous year, and over a third more than twenty five years ago.

Long-term trends in cycle traffic
Year-to-year changes in cycle traffic can be volatile due to factors such as the weather, so long-term changes are more reliable indicators of underlying trends.

In the last 25 years, cycling mileage on roads has increased by 33.7%. Cycle mileage on roads in 2018 was only around one quarter of the 14.7 billion miles ridden in 1949. Cycle traffic fell most quickly during the 1950s and 1960s, coinciding with a large rise in car ownership.

Pedal cycle traffic and car ownership (NTS) in Great Britain, 1949 - 2017

*Cycling on roads
DfT road traffic statistics report activity of cyclists on public highways, and on cycle paths and footpaths adjacent to them.
Cycle activity elsewhere (for example on canal towpaths, byways or bridleways) is not included in road traffic statistics.

Statistics from the National Travel Survey (NTS) and Active Lives Survey also provide information on cycling.
Understanding trends in cycle traffic

Information on cycling from other sources, such as the National Travel Survey (NTS), provide context for the trends in the estimates of cycle traffic from the road traffic statistics.

Between 2002 and 2017, the latest NTS figures show that average cycle mileage per person per year (including both people who cycle and those who do not) in England rose by 54%, though the trend is somewhat erratic.

When only considering respondents who cycled at least once during the survey week, the average distance cycled during the week has grown at a similar rate to the whole of England average. This suggests that people who cycle have been cycling further, but that the proportion of the population who cycle has not changed substantially.

Both road traffic estimates and NTS statistics show that cycle traffic has been growing since the 1990s, but the NTS figures suggest higher levels of growth than the road traffic estimates.

Some of this difference could be due to off-road cycling, which is not covered in the traffic statistics data collection. In 2017, nearly one-quarter of NTS respondents reported mainly cycling off-road.

Note on National Travel Survey figures

The number of actively cycling respondents in the National Travel Survey is relatively low, so figures on average cycling miles per capita and per rider are expected to fluctuate from year to year as a result of sampling error. As such, interpretation should focus on long-term trends rather than year-to-year changes.
Foreign Registered Vehicles

The statistics presented elsewhere in this release include the activity of both British and foreign-registered vehicles in Great Britain. This section discusses the proportion of vehicles in traffic which are registered outside the UK. The latest figures available cover the year 2017. See the ‘data source’ box for more information.

In 2017, 0.4% of all traffic on British roads was estimated to be accounted for by foreign registered vehicles. By vehicle type, lorry traffic had the highest proportion of foreign registered vehicles at 4.5%, this was a slight decrease of 0.3 percentage points compared to 2015. Foreign registered lorries cabotage accounted for just over 1% of road freight activity within the UK.

The South East region had the highest proportion of foreign registered vehicles of any region within Great Britain. This likely reflects that the South East is the region of arrival and departure for many motor vehicles coming from Europe through ports and the channel tunnel.

Data source

Estimates of the proportion of traffic from vehicles which are registered outside of the UK are published on the Department for Transport website every second year. Every other June, a roadside survey using Automatic Number Plate Recognition cameras captures registration marks of over a million vehicles. Registration marks originating outside the UK, the Isle of Man and the Channel Islands are identified and used to estimate the rate of foreign registered vehicles on Britain’s roads.
This section breaks down the traffic statistics by road type. Figures are presented split by the classification of the road (Motorway, ‘A’ roads, and Minor roads - ‘B’, ‘C’ and unclassified roads), by the urban/rural setting of the road.

### Overview

Traffic by Road Type

Vehicle activity is unevenly distributed across Great Britain’s road network.

In 2018, 66% of the motor vehicle miles travelled were on motorways and ‘A’ roads, despite comprising only 13% of the road network by length.

On an average day in 2018, 82 times more vehicles travelled along a typical stretch of motorway than a typical stretch of rural minor road (‘B’ roads, ‘C’ roads, and unclassified roads).

### Definitions

**Rural and Urban:** ‘Urban’ roads are those within a settlement of 10,000 people or more, following the 2011 Census definition of urban settlements. All other roads are defined as ‘rural’. See [here](#).

**Minor and Major:** Major roads include motorways and ‘A’ roads. Minor roads comprise ‘B’ roads, ‘C’ roads, and unclassified roads.
In 2018, 69.0 billion vehicle miles were travelled on Great Britain’s motorways, similar to the 2017 total (68.7 billion vehicle miles).

The overall increase in motorway traffic over the last decade comprises of differing trends by vehicle type. Van traffic has grown by 39%, whilst motorcycle and bus and coach traffic have both fallen. Motorways are vital for the movement of freight, carrying almost half (46.7%) of all lorry traffic in 2018, compared to one-fifth of car traffic.

Motor vehicle traffic by road type, 1960 to 2018 (TRA0102)

The proportion of total vehicle miles driven on motorways has increased over time, from 0.6% in 1960 to 21% in 2018. This has resulted from motorways increasing in length from 95 miles in 1960 to 2,313 miles in 2018, as well as an increase in average vehicle flow over the same period from 11,500 to 81,700 vehicles per day.
Traffic on rural roads has increased slightly (by 0.8%) between 2017 and 2018.

### Rural ‘A’ roads

- **99.9** billion vehicle miles in 2018
- 99.9% of which...

- From 1993: 8.2%
Urban and Rural traffic trends

In 2018, rural ‘A’ and rural minor roads carried around 44% of all motor vehicle traffic between them; almost 10% more than the vehicle miles travelled on urban roads. However, the average daily flow on rural roads (12,200 vehicles on rural ‘A’ roads; 1,000 vehicles on rural minor roads) was far below that on urban roads (19,000 on urban ‘A’ roads; 2,100 on urban minor roads).

Since 1993, traffic on rural roads has risen by 42% and 29% on ‘A’ roads and minor roads, respectively. This rapid growth in rural traffic contrasts with a smaller increase of 8% in urban minor roads and a relatively flat trend in urban ‘A’ road traffic (1% increase).

This pattern has varied amongst vehicle types, with van traffic on urban roads rising 61%, compared to a fall of 31% in lorry traffic over the same period.

Trends by location

Traffic has also shown varying trends geographically, with London traffic decreasing in comparison with elsewhere in Great Britain. Urban roads carried 85% of the traffic in the Greater London region in 2018.

Freight trends

The decline in lorry traffic on urban roads (a reduction of 0.9 billion vehicle miles between 2000 and 2018) has been offset by the corresponding increase in van traffic on these roads (an increase of 4.6 billion vehicle miles over the same period).

As discussed in the van and lorry sections of this report (see p.9), anecdotal evidence suggests that freight is moved more efficiently by larger lorries on motorways and rural dual-carriageways than on narrow or busy urban roads; large lorries are often restricted to certain routes. To some extent, vans may have replaced lorries for use in urban areas.
The Strategic and Local Road Networks in England

This section explores how traffic differs across the different road networks in England.

Overview

Compared with 2017, traffic increased slightly by 0.7% on England’s Strategic Road Network and remained stable on the Local Road Networks in 2018.

<table>

</tr>
</tbody>
</table>

In 2018 on the Strategic Road Network:

► Although the SRN makes up only 2.4% of England’s road network, it carried 34% of all motorised traffic in England.

► Car traffic remained stable (increasing slightly by 0.2%) from 2017, to 69.2 billion vehicle miles.

► Van traffic grew more quickly than any other vehicle type, rising 2.9% from 2017 levels to 14.7 billion vehicle miles.

► Lorry traffic also grew by 1.0% to 10.2 billion vehicle miles.

In 2018 on the Local Road Networks:

The local motorway and ‘A’ road network (major roads) carried 33% of traffic despite being only 9% of England’s road length. The remaining third of traffic was on England’s ‘B’ and ‘C’ classified and unclassified road network, which makes up 88% of roads in England.

About the SRN

The Strategic Road Network (SRN) is made up of the motorways and major trunk roads in England that are managed by Highways England (HE; previously the Highways Agency). These roads are depicted in the map.

In 2018, the SRN comprised approximately 4,513 miles of road (2.4% of the English network).

The majority of other roads in England are maintained by one of the 152 local highways authorities.

“Detrunking” and traffic trends over time on the SRN and local roads

Between 1999 and 2012, the length of the SRN reduced by 12.6%. This was a result of the detrunking programme, where the management of parts of the SRN transferred from Highways England (then Highways Agency) to the relevant local authorities.

DfT produces two kinds of time-series broken down by management to facilitate interpretation of trends over time:
- Figures in tables TRA41 figures refer to the management status of a road on 1st April in each of the historic years;
- Figures in tables TRA42 figures refer to the management status of a road as of 1st April 2018 ("static management"), to remove the effect of changing road length on vehicle miles.

All of the trends over time presented in this section use “static management” figures, as published in tables TRA42.
Share of traffic by road type

Despite making up only 2.4% of the road network by length in England, one third of all vehicle miles were driven on the SRN in 2018.

The SRN is particularly important for freight, with one third of van miles and over two-thirds of lorry miles in England being driven on the SRN in 2018.

Over 57 thousand vehicles travel along a typical stretch of the strategic road network each day. This is about four times greater than the number for a typical stretch of locally managed major roads, at 13,800.

The difference in average vehicle flow between the SRN and local roads was widened by the “detrunking” program of the last two decades, which transferred a subset of trunk roads (in general, those with lower flow) to local authority management.

Over 57 thousand vehicles travel along a typical stretch of the strategic road network each day. This is about four times greater than the number for a typical stretch of locally managed major roads, at 13,800.

The difference in average vehicle flow between the SRN and local roads was widened by the “detrunking” program of the last two decades, which transferred a subset of trunk roads (in general, those with lower flow) to local authority management.

Motor vehicle traffic in England by road management, 2000-2018

Longer term trends

Traffic on the SRN rose quickly after a period of stasis during the 2008 recession. Traffic increased 26% between 2000 and 2018.

In comparison, traffic fell more on all local roads during the recession and recovered slower. Traffic increased 6.2% between 2000 and 2018.

Useful Links

This section explores how levels and trends in traffic differ between different roads and areas of Great Britain.

In 2018, the busiest areas in Great Britain were:

- **South East** region with traffic levels of 55 billion vehicle miles
- **Hampshire** authority with traffic levels of 10 billion vehicle miles
- **M25** motorway section with an average daily flow of 169 thousand vehicles per day

At the national level in 2018, 85% of Great Britain’s traffic was on England’s roads.

Over the last 25 years, traffic growth has been fastest in Scotland and slowest in England, with 2018 figures 37% and 27% higher respectively.

Road traffic trends by the countries of Great Britain, 1993-2018

- At 1993 vehicle miles, 1993 = 100
- Scotland: +37%
- Wales: +20%
- Great Britain: +23%
- England: +31%
- England: +36%
- England: +39%
- England: +25%
- England: +37%
- England: +4%

Road traffic trends by regions of Great Britain

The South East region had the highest traffic levels in 2018, with 280 billion vehicle miles driven on its roads. This was 17% of all traffic in 2018. The South East has 12% of road length in Great Britain.

Of the five local authorities with the highest levels of traffic, three in the South East region (Hampshire, Kent, Surrey) and the other are in East of England region (Essex, Hertfordshire). These are all authorities with relatively large road networks, and they all contain some of the major motorways of Great Britain.

In 2018, all regions saw their traffic levels remain within -1% and 1% compared to their 2017 figures. Over the last 25 years, Greater London is the only region to have had a fall in traffic (-4%). All other regions have seen their traffic levels increase by at least 20%.
Road-level traffic data for Great Britain

The DfT statistics produce an estimate of traffic flow (see definition on page 2), for an average day in a given year, for each junction-to-junction link on the motorway and ‘A’ road network in Great Britain. The 2018 average flows for these roads are represented on the map.

Average daily flows on motorways and ‘A’ roads in Great Britain, 2018

Vehicles per day
- <= 5,000
- >5,000 to 10,000
- >10,000 to 15,000
- >15,000 to 20,000
- >20,000 to 25,000
- >25,000 to 30,000
- >30,000 to 35,000
- >35,000 to 40,000
- >40,000 to 45,000
- >45,000

Average daily flows on motorway and ‘A’ road links in 2018 ranged from less than 5,000 vehicles to over 200,000.

Major roads with the lowest flow levels (shown in blue on the map) tended to be rural ‘A’ roads.

The busiest roads (shown in red on the map) were in general the motorways and ‘A’ roads that make up the Strategic Road Network in England, or equivalent trunk road networks in the devolved administrations.

The road links with the highest average daily traffic flows in 2018 were sections of the M25 and M1.

4pm to 6pm are the busiest hours in weekdays

11am to 1pm are the busiest hours at weekends

On average between 2014 and 2018, motor vehicle flow was lowest in January on all road types. Flow was highest on motorways and rural roads in August. On urban roads, flow was highest on average in November. A dip in urban road traffic is evident in August, likely due to this being the school holidays when traffic associated with the school run and commuting is reduced.

Most vehicle types (cars, vans, heavy goods vehicles, buses and coaches) followed these patterns by road type.

However, motorcycles and pedal cycles had much more seasonal travel patterns. The miles travelled by these vehicle types in the summer months were over 75% higher than in the winter months.

Data source

Statistics about temporal variation in traffic flow are compiled using data from DfTs network of automatic traffic counters (ATCs).

ATCs count and classify vehicles passing over them 24 hours a day, on every day of the year, so are well suited to provide data on flow variation across a range of timescales.
Daily car traffic trends on all roads

On an average weekday in 2018, car traffic was highest in the afternoon peak, between 4pm and 6pm. This pattern was observed across the different road types (motorways, rural roads, urban roads).

On an average weekend in 2018, car traffic was highest in the middle of the day, between 11am and 1pm. The weekend peaks were at a slightly higher level to the weekday morning peak. Motorways had a slightly different pattern on Sundays, where the peak traffic flow was on average between 4pm and 5pm.

Daily van traffic trends on all roads

On average in 2018, vans had similar daily travel patterns to cars. The main differences between van and car daily patterns were:

• Weekday morning and afternoon peaks were a similar level for vans, whereas the afternoon peak is higher for cars.
• The afternoon peak for vans was an hour earlier, between 3pm and 5pm, on average.
• The proportion of vans on the road at weekends was generally lower than weekdays, even at the peak periods.

Daily lorry traffic trends on all roads

Lorry travel patterns, for an average weekday in 2018, showed a more constant level of traffic in the middle of the day than cars and vans. There were much lower numbers of lorries on the roads at the weekends than on weekdays.

On motorways, lorry weekday peaks were in the early afternoon (1pm to 3pm), except on Friday when the highest lorry traffic was at 11am to 12pm.

On other types of road, the highest weekday levels of lorry traffic were in the morning (8am to 11am).
Impacts of road traffic

Whilst traffic levels can act as a barometer of trends in the economy and society, traffic itself also has a variety of impacts on human life and the environment.

Road Accidents

Increases in traffic tend to lead to greater numbers of interactions between road users. Therefore, all else being equal, a rise in traffic is expected to increase the total number of accidents. However, per mile travelled, the risk of being killed or seriously injured in a road accident has fallen almost every year from a peak of 165 deaths per billion vehicle miles (bvm) in 1949 to 5.2 deaths per bvm in 2017.

There are a range of reasons for the fall in fatality rates, including: improvements in education and training; improvements in vehicle technology and highway engineering; improvements to trauma care; the introduction of road safety policies, such as speed limits; enforcement of legislation; and behavioural change.

Number killed or seriously injured in Great Britain, 2000 to 2017

![Graph showing number killed or seriously injured in Great Britain, 2000 to 2017]

Source: DfT road accident statistics

Journey times and reliability

It might be expected that an increase in traffic would result in worse congestion, and a decrease in traffic result in lighter congestion. However, the relationship is not that simple. The effect of an increase in traffic on congestion will depend on where and when the extra vehicle miles occur. For example, where congestion is most severe during the morning and evening rush-hour on weekdays, an increase in traffic at these peak times could have a large effect on congestion levels, but at other times of day may have little effect.

Another key factor is changes in the capacity of roads and junctions. For example, improving a junction may ease congestion while at the same time allowing an increase in traffic.
Greenhouse gas emissions and air quality

Road transport accounted for 25% of the UK’s CO₂ emissions in 2017.

CO₂ emissions from road transport fell by 2.0% between 2000 and 2017, despite a 12.9% rise in vehicle miles travelled over the same period.

Fuel efficiency has been improving, and sales of ultra-low emissions vehicles have risen rapidly in recent years. The number of newly registered ultra-low emissions vehicles in 2018 was 63,992 (2.2% of all newly registered vehicles) compared to 4,314 in 2013.

Another environmental impact of road traffic is emission of Nitrogen oxides (NOₓ) and particulate matter smaller than 10μm in diameter (PM₁₀). Emissions of both of these pollutants from road transport in the UK fell between 2000 and 2017.

Index of road traffic and emissions of CO₂, NOₓ and PM₁₀ from road transport, 2000 to 2017

Road condition

Over time, road vehicles cause damage to the roads they drive along, with heavier vehicles having a disproportionately large impact.

In 2017/18, 3% of the local ‘A’ road network in England should have been considered for maintenance. This is the same as in 2016/17.

In 2017/18, £4.4 billion was spent on the maintenance of roads in England. Of this, £1.0 billion was spent on motorways and ‘A’ roads managed by Highways England and £3.3 billion on local authority managed roads.

Road Use

Road transport is the main transport mode for individuals and businesses.

According to the 2017 National Travel Survey, in England...

- **74%** of adults have a driving licence - 80% of men, and 69% of women
- **76%** of households have access to a car, with 35% having two or more.
- **61%** of all personal trips are made by car
- **78%** of distance travelled per person per year are personal trips by car
- **85%** of people travel by car at least once or twice a week

In 2017, within the UK road freight sector...

- ...there were 48,134 road freight enterprises ...
- ...contributing £12.0 billion to the UK economy.

Roads are used for a wide variety of purposes...

- The largest share of personal car mileage in England was for commuting and business trips.
- One-quarter of the goods moved by British HGVs in the UK comprised food products, beverages and tobacco.

### Car driver mileage in England by trip purpose, 2017

- **36%** Commuting and business
- **32%** Visiting friends and other leisure
- **16%** Personal business and other escort
- **12%** Shopping
- **3%** Education

Source: National Travel Survey

### Share of goods moved by GB registered lorries, 2017

- **27%** Food products, beverages and tobacco
- **27%** Products of agriculture, forestry, raw materials
- **19%** Textile, leather and wood products
- **17%** Other products
- **16%** Machinery and equipment
- **15%** Metal, mineral and chemical products
- **5%** Other products

Further information

An overview of the statistics on roads, and how they are used, can be found in the DfT report ‘Road use statistics’.
Factors affecting road traffic

Components of road traffic

Changes in road traffic can result from a change in the number of vehicles, a rise or fall in how intensively each vehicle is used (average annual mileage), or a combination of the two.

The growth in motor vehicle traffic since 1950 has largely been due to an increasing number of licensed vehicles, although there have been fluctuations in average annual mileage.

Population growth and density

Population changes affect traffic levels. There has been a steady growth in population over the last twenty years, increasing the number of people needing to travel. Car is the main mode of transport for most people, with almost 90% of passenger mileage on roads, and over three-quarters of the goods that people use being transported by road.

The geographic pattern of population growth is a key factor in how traffic is affected. The more rurally people live, the further they travel. The 2017 National Travel Survey showed that those living in rural hamlets and villages travel 96% further than those in urban areas.

Incomes, the economy, and employment

Fluctuations in road traffic levels tend to coincide with events such as changes in the economy (including GDP, see the chart to the right) and peoples’ disposable incomes, which influence car ownership and the trip behaviour of car owners.

Over the long term, the relative cost of purchasing a motor vehicle has decreased, and this has contributed to increases in car ownership.
According to the National Travel Survey, only 14% of British households had access to a car in 1951, versus 76% in 2017. Scope for further growth in ownership remains as, in 2017, 44% of households in the lowest income quintile were without access to a car.

How heavily cars are used is influenced by the cost of fuel, as well as associated changes in the cost of alternative modes of transport (i.e. buses and trains).

Demography

Personal travel behaviour also varies with factors such as age and sex, due to changing needs at different life stages and cohort effects. The demography of the driving population has changed over time. In particular, females and older age groups are much more likely to hold a licence now than thirty years ago. The proportion of young adults (aged 17-20) with a full driving licence has decreased since the 1990s when it was highest for this age group.

Proportion of full driving licence holders by age, in 1975/6, 1995/7 and 2017

Related data

► DfT Road traffic forecasts - www.gov.uk/government/publications/road-traffic-forecasts-2018
These statistics were designated as National Statistics in February 2013.

National Statistics are produced to high professional standards set out in the National Statistics Code of Practice. They undergo regular quality assurance reviews to ensure they meet customer needs.

Details of Ministers and officials who receive pre-release access to these statistics up to 24 hours before release can be found here: www.gov.uk/government/publications/pre-release-access-lists-for-road-traffic-speeds-and-congestion-series

Traffic statistics methodology: strengths and weaknesses

Annual estimates make use of data from around 8,000 manual traffic counts in addition to continuous data from a national network of automatic traffic counters. These data sources produce accurate estimates on traffic levels in Great Britain by vehicle type and by road type.

A detailed explanation of the methodology used to produce DfT road traffic statistics can be found online in Annual road traffic estimates: methodology note at www.gov.uk/government/publications/road-traffic-statistics-guidance.

Whilst road traffic data is accurate at a high level of aggregation, it should be noted that:

► Although we produce traffic breakdowns by local authorities, traffic at this level is not robust, due to the sample size of the minor road data and must be treated with caution.

► Estimates for pedal cycle traffic only include cycling on roads, or paths directly adjacent to the road, and do not include estimates of cycling on other routes such as canal paths. Therefore, they may not give a complete representation of cycling.

► During June, every second year, a roadside survey is carried out collecting information about vehicles travelling on the road which identifies vehicles with registration marks originating outside United Kingdom. This information has been used to produce estimates of the rate of foreign registered vehicles on Britain’s roads, which are presented in tables TRA32. These figures are designated as official statistics but not as National Statistics and should be treated with caution as the sample size is relatively small (over 7,000 observations of foreign registered vehicles out of 1.1 million total observations). Particular attention should be paid to the confidence interval associated with each statistic and in some cases statistics have not been produced as the sample size is too small. This survey is next due to be carried out in 2019 and therefore the next estimates of foreign vehicle traffic will be published in 2020.

► The Road Traffic statistics series consistently reports higher levels of vehicle kilometres for lorries than the Road Freight statistics series. This can mainly be attributed to difference in data collection. A methodology note on this issue has been published and can be found in our statistical guidance notes online here: www.gov.uk/government/publications/road-traffic-statistics-guidance.
Background information

Users and uses of road traffic estimates

We continuously review the content of these statistics to ensure they are meeting users’ needs. We welcome feedback via email and the team can be contacted at roadtraff.stats@dft.gov.uk.

A summary of the feedback we have received from users in a previous consultation can be found in ‘Meeting customers’ needs: Users and uses of road traffic statistics and data’. We continue to welcome any feedback on these statistics.

Road traffic data are a key source of management information on the country’s infrastructure. Main uses of road traffic statistics include:

► National Atmospheric Emissions Inventory (NAEI)

Road traffic statistics are used to produce the National Atmospheric Emissions Inventory (NAEI), a legal requirement for EU Air Quality Directives, and for the UN Framework Convention on Climate Change.

► Transport Modelling

The Department for Transport’s National Transport Model uses most traffic and speeds outputs to make forecasts and to inform policy decisions on a broad range of issues.

► Local transport planning

Local Authorities (including Transport for London) and devolved governments use the data for transport planning, road engineering and policy monitoring at a regional or local level.

► Road accident and safety statistics

Road accident and safety statistics use annual and quarterly traffic estimates to produce road safety and accident rates, as required for the Strategic Framework on Road Safety.

► Ministry of Housing, Communities and Local Government

This department uses traffic data on major roads to contribute towards the funding settlement for local authorities.

► Public Users

The Department for Transport receives over 200,000 visits to the traffic counts website (roadtraffic.dft.gov.uk) and its underlying datasets, which provide street-level traffic data for every junction-to-junction link on the ‘A’ road and motorway network in Great Britain.

Next release

The next annual traffic statistics release is expected to be published in May 2020, reporting 2019 traffic figures.

Provisional figures for 2019 will be published on a quarterly basis during 2019-20. The next provisional figures, for the year to end Mar 2019, are due to be released 13 June 2019.
