

Title: Robust Monetary Policy Framework for Emerging Markets

Policy motivation: The primary objective of most central banks, whether or not they explicitly target inflation, is to keep inflation low and stable. The choice of the right price index that should be the focus of the inflation objective is a central operational issue in implementing monetary policy. This question takes on a very different hue in low- and middle-income economies. In these economies, food expenditures account for nearly half of total household expenditures, and a large proportion of the population works in a cash economy with little access to the formal financial system. The main objective of this research project is to analytically determine the price index that central banks should target in economies that have these features. This can help central banks implement monetary policy in a manner that promotes macroeconomic stability and economic welfare.

Policy Impact: Our analysis suggests that it may not be appropriate for central banks in developing economies to target core inflation—which excludes volatile food and energy prices—even though classical theoretical models suggest that core inflation is the proper target for monetary policy. Adopting flexible headline inflation targeting—a target based on headline rather than core inflation and with some weight on the output gap may be a better policy choice. This issue is highly policy relevant in many developing economies that are now facing rampant food price inflation and are looking for frameworks to determine the appropriate monetary policy response.

Audience: Central banks in general, and central banks of emerging markets in particular.

Implications:

- **In emerging markets, changes in food prices cannot be treated just as supply shocks that have no implications for monetary policy.** Low levels of financial development, the high share of food in household expenditures, and the nature of food (low elasticity, and a necessary good) imply that relative food price movements affect aggregated demand. This may call for a different response to food price inflation in these economies as compared to advanced economies.
- **The widely-accepted analytical result that targeting core CPI inflation stabilizes overall inflation and the business cycle needs a careful re-examination in the case of emerging market economies.** As food price changes affect aggregate demand in these economies, leaving them out of the price index that is the focus of monetary policy actions may have adverse welfare consequences in these economies.

Brief Summary of Research: In the academic literature, the choice of price index for inflation targeting central banks has been guided by the idea that inflation is a monetary phenomenon. Since fluctuations in food and energy prices are non-monetary in nature, reacting to them may not be desirable and could even prove counterproductive. In addition, if households have access to the formal financial system, they can fully insure against these

transient and volatile shocks, making central bank intervention unnecessary. Thus, to deliver price stability – the key role of central banks – the optimal strategy is to target the underlying core inflation (excluding food, energy and other volatile components of headline inflation).

However, most of the assumptions that these analytical results are based on are relevant only for advanced economies. Emerging market economies differ from advanced economies in some key respects. A substantial fraction of households in emerging markets do not have access to formal finance, and they spend a major share of their household expenditures on food (and fuel). Hence, changes in food and fuel prices have a considerable bearing on the consumption decisions of these households. Since expenditure on food in total household expenditure is high and demand for food is relatively inelastic, households in these economies factor in food price inflation while bargaining over wages. Through this channel, food price inflation may feed into inflation expectations. Thus, in emerging markets even inflation expectation targeting central banks have to be concerned about food price inflation.

We develop a simple model incorporating the distinctive features of emerging market economies, although our results turn out to have broader applicability. We assume that a fraction of households in the economy do not have access to formal finance and they consume their wage income in every period. We look at the welfare implications of targeting headline inflation and core inflation under these settings to determine the optimal price index.

Our results suggest that under these settings the central bank should target headline inflation. Since a fraction of households cannot borrow, their consumption path is determined by their wage income, and demand of these households is insensitive to changes in interest rates– the primary instrument of monetary policy. Thus, the relative price of food not only affects aggregate supply, but through its effects on real wages, also influences aggregate demand (in other words, food price shocks are no longer a pure supply shock as commonly treated in the classical models). It also implies that in order to affect aggregate demand, the central bank has to respond to food price shocks. The presence of households with no access to finance also breaks the comovement of inflation and output (as inflation and output may now move in opposite directions). Thus, stabilizing core inflation is no longer sufficient to stabilize output as in these markets.

Implementation: Our results suggest that in emerging market economies the choice of core inflation as the inflation objective needs careful reconsideration. When the price of food has a significant influence on the consumption choices of households, there may be merit in targeting the overall price index (headline inflation). This issue is important in the present global economic context, with many developing economy central banks grappling with the issue of how to deal with the recent surges in food and fuel prices. Our analysis suggests that in economies with low levels of financial development, the solution of neglecting food price inflation and focusing just on core inflation could have adverse welfare consequences. Our research does not directly examine the precise tools through which central banks in emerging markets should target headline inflation but a combination of interest rate policy and flexible exchange rates could help cope with both domestic and imported sources of inflation.
