INTRODUCTION

Cassava (Manihot esculenta Crantz) is one of the most important staple foods in the human diet in the tropics, cultivated in areas considered marginal for other crops. Because of its high yield and tolerance to drought and great ability to survive uncertain rainfall patterns, it is considered a contributor to food-security against famine, requiring minimal inputs and making it an important crop for drought prone areas of tropical and sub-tropical Africa, Asia and Latin America.

When water is available, cassava maintains a high stomatal conductance with high internal CO2 concentration; but when water becomes limiting, the stomata are closed in response to even small decreases in soil water potential. In addition, leaf area growth is decreased in response to water stress and is rapidly reversed following the release from stress. This suggests that the ability to regulate numerous plant processes to rapidly change course is the key for cassava success under unfavorable weather.

This project aims to determine the best traits to be used in breeding programs for drought tolerance by elucidating the mechanisms of cassava’s remarkable tolerance to drought and to identify trait-marker associations for the development of a more cost-effective breeding process for drought tolerance that can be used for cassava and other crops.

Specific Objectives:

1. Improve the understanding of the drought tolerance mechanisms in cassava.
2. Select contrasting cassava genotypes for tolerance to drought environments.
3. Identify molecular markers for drought tolerance traits via QTL and candidate gene mapping in cassava.
4. Assess the benefits of transgenic over-expression of a gene for improved leaf retention introduced into the Manihot esculenta gene pool.
5. Strengthen the partnership among institutions involved with plant breeding programs for drought tolerance.

METHODS / ACTIVITIES

To understand the cassava drought tolerance mechanisms:

1. Selection of contrasting genotypes for drought tolerance
2. Estimation of the drought tolerance mechanisms in field (in controlled conditions)

Parameters:

- Leaf conductance: transpiration; photosynthesis
- Soluble carbohydrates
- Accumulation of specific low molecular weight proteins
- Abscisic acid (ABA) and phasic acid (PA) accumulation
- Accumulation of non-structural carbohydrate
- Leaf area: leaf retention; root depth; # of roots; root dry matter; starch; productivity; tolerance to cassava green mites (CGM) and other pests

Identification of cassava genotypes with wide diversity for drought tolerance traits:

1. Crosses 20 Tolerants (TOL) vs 10 Susceptibles (SUS) and self of TOL
2. Selection of the 4 best parental combinations and progenies evaluation
3. 200 seeds of each cross germinated to produce 40 copies to be shared with Brazil, Colombia, Ghana and Tanzania
4. At each local: in vitro multiplication (rapid propagation) to evaluate the segregating populations.
5. In the segregating populations and parents: evaluation of water deficit effects
6. Identification of genotypes with good drought tolerance incorporated into breeding program or directly used by farmers

Identification of molecular markers associated with drought tolerance genes:

1. Four segregating populations (F1); progenies from selfing (S1) and parents → evaluated in the replicated trials. The target sites will be in drought prone regions of Brazil, Colombia and Tanzania (Fig. 1) drought and grown
2. Segregant parentals lines → genotyped with >600 SSR markers from cassava genetic map

In vitro multiplication of the contrasting drought tolerant varieties

The selected contrasting varieties have been multiplied by in vitro micropropagation procedures at CIAT. Individual copies of each contrasting genotype were produced and shipped to Brazil (Embrapa). These copies were in vitro multiplied and acclimated in greenhouse to produce plants for field evaluation.

Establishment of a crossing block

The selected contrasting genotypes were planted in September 2005 in a crossing block at CIAT for pair-wise crosses to produce segregating populations for genetic mapping of traits associated with drought tolerance.

Establishment of field trials in the target sites

To evaluate drought tolerance related traits, field experiments were established in the target sites in Brazil, Colombia, Tanzania, and Ghana, using drought tolerance contrasting cassava varieties:

Brazil: Two 5-plant groups of 60 contrasting varieties were planted (May/2006) in an irrigated field in Petrolina. 3-4 months after planting (MAP), the irrigation, in one group, will be stopped and the growth and physiological parameters will be evaluated (Fig. 3).

Colombia: Two 7-plant groups of 36 varieties were planted (Nov/2005) in an irrigated field in two sites of the Tolima Department. Two months after planting (Day 0) the irrigation, in one group, was stopped and sampling were at Days 0, 15, 30, 45, 60. The last sampling will be at harvest time (11-12 MAP). The parameters/samples were: plant height; leaf temperature; leaf retention; leaf and stem samples for ABA and sugars. At harvest, the production parameters will be added.

At CIAT, 15 contrasting varieties, planted (Mar/2006) in 60kg plastic bags, were evaluated in a screenhouse under control and water deficit (no irrigation after Day 0 = 2 MAP). The sampling were at Days 0, 15, 30, 45, 60. At each Day, 5 plants were harvested. The parameters were: soil moisture; plant height; leaf retention; leaf relative water content; total biomass (FW); leaf, stem and root tips samples for ABA and sugars); root biomass (FW and DW); # of storage roots. The roots were stored for volume and length analysis using the WinRHIZO software. For the same 15 varieties, two 3-plant groups were planted (Jun/2006), under open sky, in 60kg plastic pots. Two MAP the irrigation, in one group, was stopped and the pots covered with a plastic film. The parameters and samples will be collected at the harvest time, around 10-11 MAP.

The data and samples collected in Colombia are in process of statistical and lab analysis at Cornell University.

Tanzania: Nine contrasting local and improved varieties were selected from two yield trials conducted in 2005 at Hombolo site in Dodoma. These varieties were planted (Feb/2006) and the harvest is scheduled for 12 MAP. In the meantime, the following parameters is being collected: plant establishment; disease and pest incidence; plant height.

Ghana: Ten contrasting cassava genotypes, selected from SARF germplasm and from farmers, were planted (Aug/2005). The data recorded include: dry weight (leaves, petioles, stem, adventitious roots, tuber roots); # of leaves, leaf scars, tuber roots; length of adventitious and tuber roots; plant height; width of plant canopy.
