Some of the graphs in this document make meaningful use of colour. This means that important differences may not be visible if the report is printed out in grey scale rather than viewed on screen.

This report was produced in L^AT_EX, using Lyx as an editor and using knitr to process R code embedded in the source files.

1 overview

This appendix contains tables and graphs providing technical information in support of the discussions in annexes A, B and C of this report.

This information is not intended to be self-explanatory, providing only notes that allow the reader to find on the web many explanations of the technical issues involved. There are three sections:

- detailed information about the analysis of UCE data described in annex A and referred to in annex C
- IRT analyses of NAPE data discussed in annex B
- IRT analyses of PLE marks at the item level described in annex A and referred to in annex C.

The main text of the report includes high-level descriptions of key aspects of the issues explored at greater length in the annexes.

2 UCE data

Table 1 provides the distributions (as percentages) of the divisions in the UCE sample data set we analysed. The table has been sorted by the total number in each subject (as a percentage

of the total number in the sample – this column is headed ‘% of total’). The column headed ‘Prop Div 1’ is a simple categorisation of the proportion (shown in the column headed ‘%1’) of the total subject getting division 1. The column headed ‘Prop PLE Div 1’ is a categorisation of the proportion of the subject cohort with a Division 1 result in PLE – a measure of the academic competitiveness of the subject cohort. Those subjects with a proportion of students getting PLE Division 1 similar (+/- 10%) to the proportion in the total cohort who got Division 1 in PLE have been labelled ‘similar’. Those labelled ‘lower’ have a lower proportion than this, those labeled ‘much higher’ have a proportion twice (or more) that found in the cohort as a whole.

The overwhelming impression is that division 1 and division 2 results in the larger subjects are very rare.

Setting aside the very small subjects, there are several subjects showing a tendency for a larger proportion of division 1s to be associated with a cohort having a higher proportion of PLE division 1s (a more ‘academic’ cohort) – for example, Luganda, Political Education, French, Foods & Nutrition, Lango and Typewriting. However, there are significant exceptions – for example, Art, Lusoga, Technical Drawing, Computer Studies. There may be some other factors at work, such as the difference between more ‘academic’ and more ‘practical’ studies as well as, perhaps, some gender-related differences in participation and achievement.

Table 2 provides the distribution (in percentages) of the PLE results of students in this sample data set.

Table 3 summarises the results of using mixed effects modelling of UCE English division¹ in terms of so-called² fixed effects of BirthYear (number of years before or after 1996), Gender, PLE Year (number of years before or after 2010), PLE English, Mathematics, Science and SST. Examination Centre (coded as ‘CenterNo’) was used as a so-called ‘random’ effect to see if there are any systematic differences between groups of students in different centres, once the fixed effects have been taken into account.

The technique of mixed effects modelling goes by a range of names in different disciplines. In education, it is often known as hierarchical linear modelling (HLM). It is a technique that is very useful where data sets at the individual level – in this case, students taking UCE examinations – have a meaningful grouping – in this case, examination centres and where the numbers in each group vary.

The information about each fixed effect in table 3 is a coefficient (with an indicator of the extent to which it may be thought of as different from zero) and a standard error in parentheses – for example 0.002). For the random effect (an intercept for each centre), the variance is listed (0.34). This can be compared with the total variance unaccounted for by the fixed effects: the sum of the random effect variance and the residual variance. In this case, centre number accounts for about 19.5 per cent of this variance – a noticeable proportion.

The title of the table includes a pseudo R squared value (the ratio of the explained variance to the total variance). Such values cannot be used to compare models but do give some idea of how well the model works.

Table 4 summarises the results of similar analyses for the nine large and medium sized subjects and the overall UCE division. Values are given for fixed effects coefficients when these are significant (a t-value greater than 3.0).

¹ As discussed in annex A, divisions are probably not an interval scale and would be better modelled as ordinal categories or in terms of the underlying raw scores.

² These are neither fixed nor effects in the implied sense of causation.

Table 4: Coefficients in mixed effect modelling UCE result from various parameters

3 NAPE

This section provides tables and Wright Maps (item-person maps) for selected NAPE tests in P 3, P6 and S2.

For each test, we provide

- three tables:
 - the outfit and infit statistics
 - the item parameters from fitting a one parameter IRT model (location values)
 - the item parameters from fitting a two parameter IRT model (location and slope values)
- one wright map, in which item thresholds are plotted on the right with a histogram showing, on the same logit scale, the distribution of person scores on the left

Basic IRT models are based on an assumption that a single latent trait (or ability) is measured by a test. The probability that a person will get an item right, says the model, is a function of a person's ability and the characteristics of an item. The item's characteristics are represented as a probability curve. Such a curve is specified by its mathematical form and two parameters: a location (interpretable for dichotomous items as a difficulty) and a slope (interpretable as discrimination – steep curves mean that the probability of getting the item right changes rapidly with ability).

Using IRT means the data set is analysed to identify information about items in a way that means that information about items is, unlike classical test statistics, intentionally not dependent on the information about persons – if the model applies, then the information about items is separated from the information about the persons who actually took the test.

IRT requires that items are locally independent – the chance of getting any item correct is dependent on ability, not on getting another item.

Tables such as 5 provide an indication of how well the items in the test fit the model. Two measures are given (both based on a chi-square measure of the difference between observed and predicted):

- outfit (together with a t-value and associated probability of getting a value as large as this if the model is correct)
- infit (together with a t-value and associated probability of getting a value as large as this if the model is correct).

Outfit and infit values have an expected value of 1.0 – so values close to 1.0 (say from 0.5 towards 2.0) suggest a more-or-less satisfactory fit. A value for an item outside this range suggests some potential issues with the item. Outfit values will be outside the expected range when there are enough exceptions to the expected patterns of responses (for example, low ability persons getting a 'difficult' item correct). Infit is a weighted measure that pays more attention to the middle ranges of ability and reflects the extent to which the actual variance on the item is close to the variance predicted by the model.

Tables such as 6 and 7 provide item parameters resulting from fitting IRT models. Item parameters appear in columns headed Axsi_cat1 (location) and Bxsi_cat1 (slope).

Table 6 provides the results of fitting a one parameter IRT model. Using a one parameter IRT model means assuming that the slope parameters for items are all the same – for dichotomous items, a value of 1.0 and, as can be seen in this table, 1.0, 2.0, 3.0 and so on for each score category.

Where the response is dichotomous, the item parameters for location in the tables can be seen as difficulties. Where the response is polytomous, the item parameters are the δ (delta) parameters in the partial credit model. These are not interpretable as difficulties.

Using a two parameter IRT model means assuming that the slope parameters for items can be different – see for example, table 7.

We used the information in these tables to support our comments about redundancy of items – items providing essentially the same information.

The Thurstonian thresholds (item thresholds) in the wright maps (for example, 1) show the ability (on the logit scale) at which the probability of getting at least this score or higher (if the item is polytomous) is 0.5. Thresholds are represented by coloured symbols. Wright maps give a visual sense of the spread of items across the ability scale and the extent to which categories in polytomous items are separated. Overlapping or nearly overlapping category symbols suggest that the different categories (scores) on this item do not represent real differences in ability. Tables such as table 8 provide the numerical values of these thresholds.

We did not have the data we would have needed to put the cut-offs for proficiency levels onto these maps.

Table 32: thresholds for IRT analysis of NAPE Mathematics 2014 grade s2

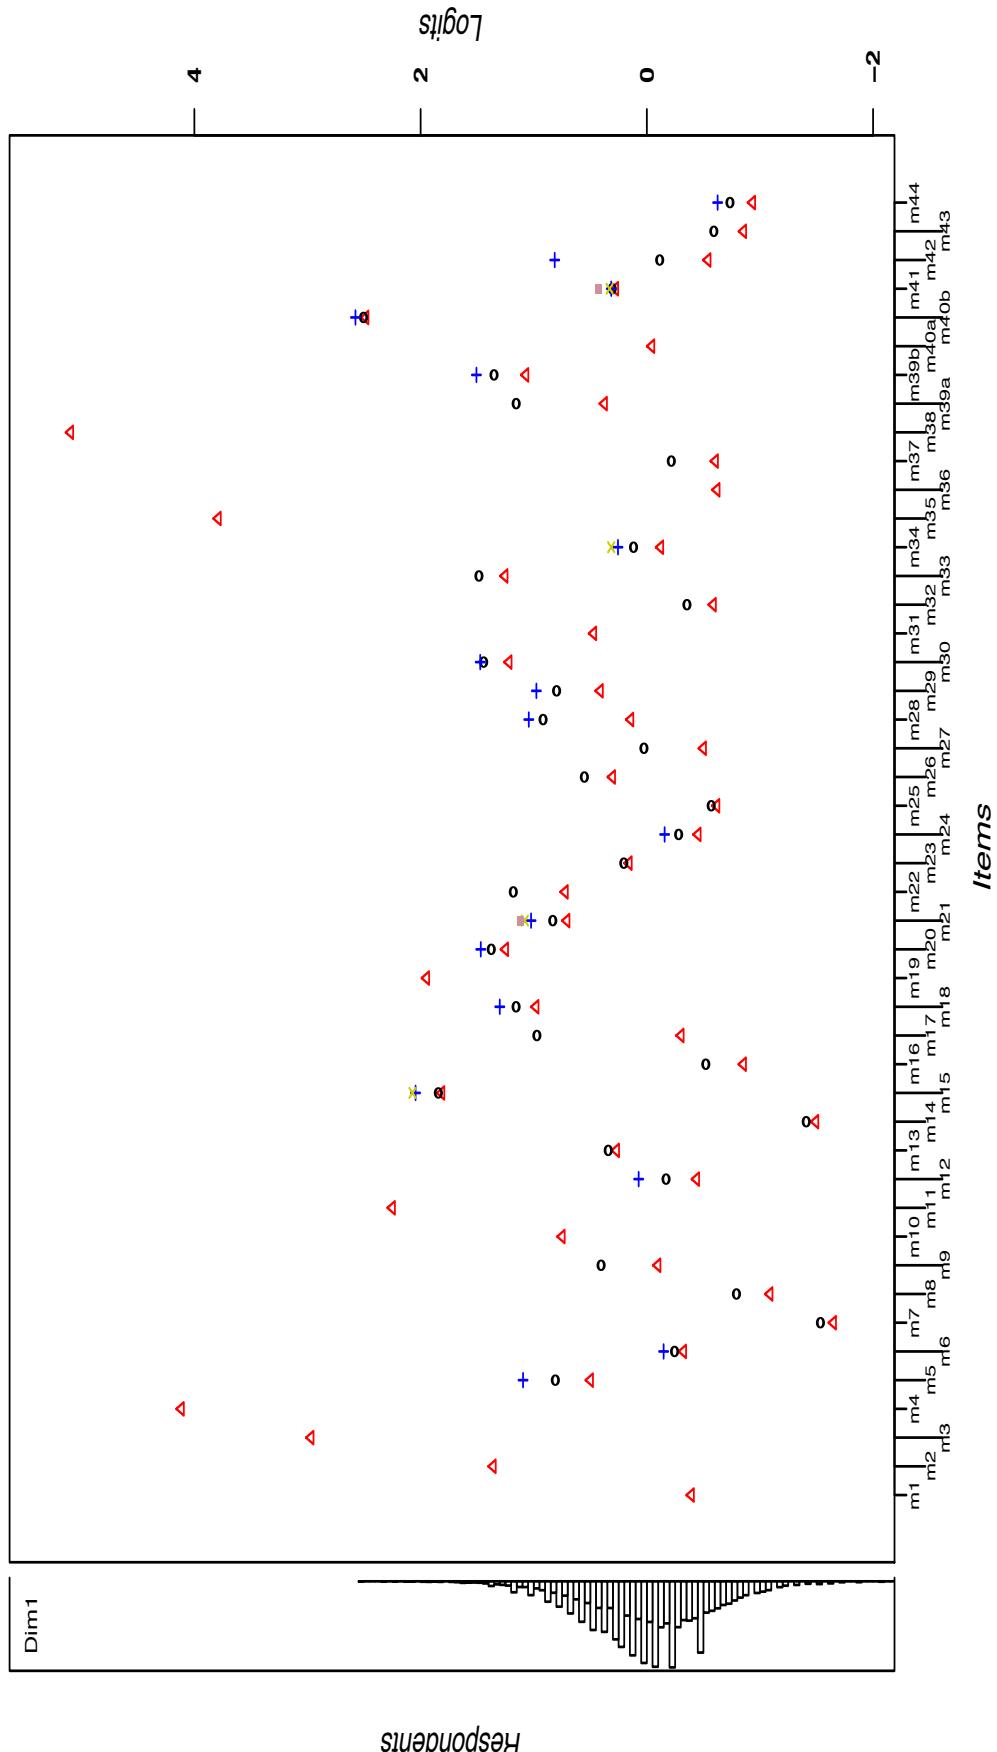

Figure 7: Wright Map for items in 2014 NAPE Mathematics grade S2

4 PLE

We had item scores for 300 sample papers in each of four PLE subjects. As is clear from figure 8, the distributions of raw scores in these samples was very different from what might be expected in a random sample.

This does not prevent us from using IRT to analyse these sets of scores, since IRT analysis (if the data fits the model) produces item parameters that are independent of person parameters. This section provides tables and Wright Maps (item-person maps) for PLE examinations in English, Mathematics, Science and SST for 2015.

For each examination, we provide

- three tables:
 - the outfit and infit statistics
 - the item parameters from fitting a one parameter IRT model (location values)
 - the item parameters from fitting a two parameter IRT model (location and slope values)
- one wright map, in which item thresholds are plotted on the right with a histogram showing, on the same logit scale, the distribution of person scores on the left

Basic IRT models are based on an assumption that a single latent trait (or ability) is measured by a test. The probability that a person will get an item right, says the model, is a function of a person's ability and the characteristics of an item. The item's characteristics are represented as a probability curve. Such a curve is specified by its mathematical form and two parameters: a location (interpretable for dichotomous items as a difficulty) and a slope (interpretable as discrimination – steep curves mean that the probability of getting the item right changes rapidly with ability).

Using IRT means the data set is analysed to identify information about items in a way that means that information about items is, unlike classical test statistics, intentionally not dependent on the information about persons – if the model applies, then the information about items is separated from the information about the persons who actually took the test.

IRT requires that items are locally independent – the chance of getting any item correct is dependent on ability, not on getting another item.

Tables such as 33 provide an indication of how well the items in the test fit the model. Two measures are given (both based on a chi-square measure of the difference between observed and predicted):

- outfit (together with a t-value and associated probability of getting a value as large as this if the model is correct)
- infit (together with a t-value and associated probability of getting a value as large as this if the model is correct).

Outfit and infit values have an expected value of 1.0 – so values close to 1.0 (say from 0.5 towards 2.0) suggest a more-or-less satisfactory fit. A value for an item outside this range suggests some potential issues with the item. Outfit values will be outside the expected range when there are enough exceptions to the expected patterns of responses (for example, low ability persons getting a 'difficult' item correct). Infit is a weighted measure that pays more attention to the middle ranges of ability and reflects the extent to which the actual variance on the item is close to the variance predicted by the model.

Tables such as 34 and 35 provide item parameters resulting from fitting IRT models. Item parameters appear in columns headed Axi_cat1 (location) and Bxi_cat1 (slope).

Table 34 provides the results of fitting a one parameter IRT model. Using a one parameter IRT model means assuming that the slope parameters for items are all the same – for dichotomous items, a value of 1.0 and, as can be seen in this table, 1.0, 2.0, 3.0 and so on for each score category.

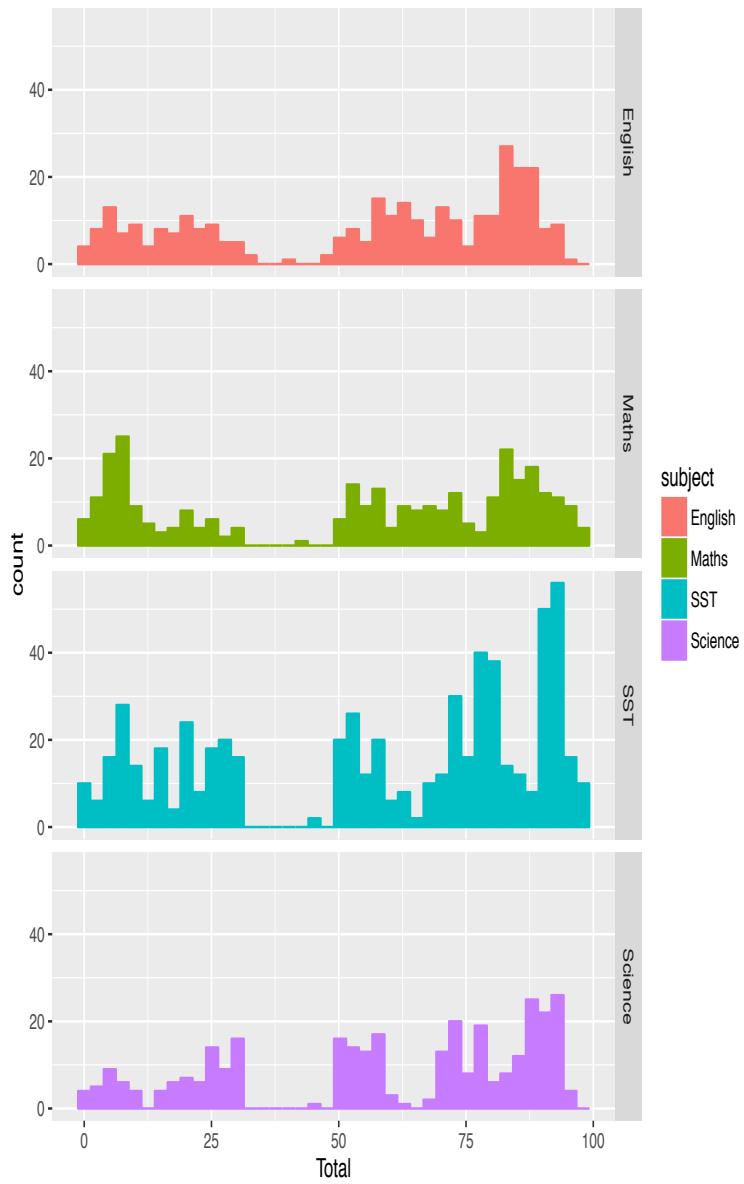

Figure 8: Distributions of raw score totals in (non-random) sample of PLE scores for four subjects 2015

Where the response is dichotomous, the item parameters for location in the tables can be seen as difficulties. Where the response is polytomous, the item parameters are the δ (delta) parameters in the partial credit model. These are not interpretable as difficulties.

Using a two parameter IRT model means assuming that the slope parameters for items can be different – see for example, table 35.

We used the information in these tables to support our comments about redundancy of items – items providing essentially the same information.

The Thurstonian thresholds (item thresholds) in the wright maps (for example, 12) show the ability (on the logit scale) at which the probability of getting at least this score or higher (if the item is polytomous) is 0.5. Thresholds are represented by coloured symbols. Wright maps give a visual sense of the spread of items across the ability scale and the extent to which categories in polytomous items are separated. Overlapping or nearly overlapping category symbols suggest that the different categories (scores) on this item do not represent real differences in ability.
