

Assessment of Salmon Stocks and Fisheries in England and Wales

ASSESSMENT OF SALMON STOCKS AND FISHERIES IN ENGLAND AND WALES

**Standing report on methods, approaches and wider stock
conservation and management considerations**

Acknowledgement:

This background report has been compiled jointly by staff from the Cefas Salmon and Freshwater Fisheries Team at Lowestoft and fisheries personnel from the Environment Agency and Natural Resources Wales. The monitoring and assessment of salmon stocks is funded by Defra and Welsh Government. All the participating organisations would like to extend their thanks and recognition to the various operational fisheries personnel who collect and compile the data used in the annual assessment of salmon stocks (now published as a separate report). Thanks are also due to the National River Flow Archive at the Centre for Ecology and Hydrology for providing river flow data, to the Game and Wildlife Conservation Trust for data relating to the River Frome, to the General Secretary of ICES for permission to cite the reports of the ICES Working Group on North Atlantic Salmon, to NASCO for permission to include their summary of regulatory measures for the high seas fisheries and to Graphic Solutions (E.A.) Limited for preparation of the final report.

FOREWORD

Annual reports on the status of salmon stocks and fisheries in England and Wales have been produced since 1997. For much of this period, they have been prepared jointly by the Centre for Environment, Fisheries and Aquaculture Science (Cefas) and the Environment Agency. However, from 1 April 2013, the functions of the Environment Agency in Wales transferred to a new body, Natural Resources Wales (Cyfoeth Naturiol Cymru) (NRW), which is now responsible for salmon management and regulation in Wales. All three organisations have contributed to the annual assessment report since 2014, and it is anticipated that similar arrangements will continue to apply for future assessments.

Up until the 2013 assessment, each annual report was designed to stand alone, to avoid the need to refer to previous reports for background information. However, this resulted in much of the descriptive information being very similar to that in reports for previous years. From 2014, therefore, and in the interest of streamlining procedures, it was decided to include the more generic background information in this standing report and to produce a separate shorter annual assessment containing the latest tables and figures. Both documents are available on the Gov. UK website.

A key purpose of the annual assessment is to provide information on the status of salmon stocks and fisheries in England and Wales to the International Council for the Exploration of the Sea (ICES), which is used, in turn, to provide advice to the North Atlantic Salmon Conservation Organisation (NASCO). An account of the way in which ICES uses the national data presented in the annual assessment is provided in Annex 5.

The objectives of NASCO are to contribute to 'the conservation, restoration, enhancement and rational management of salmon stocks'. In particular, NASCO is responsible for negotiating the quotas for the marine salmon fisheries operated in Greenlandic and Faroese waters. Annexes 4 and 5 give further information on NASCO and ICES.

The full list of information requested by NASCO from ICES for the latest annual meeting is provided in the annual assessment report. Key requests relating to annual events include a need to provide:

- *an overview of salmon catches and landings, including unreported catches by country and catch and release, and production of farmed and ranched salmon;*
- *a description of the key events of the fisheries and the status of the stocks for the latest assessment year;*
- *age-specific stock conservation limits for all stocks; and*
- *a compilation of releases of tagged fish.*

NASCO seeks information on the fisheries relating to *catches, gear, effort, composition and origin of the catch (including escapees and sea-ranched fish), and rates of exploitation*. These headings have, therefore, been used in the appropriate sections of this report and are also reflected in the structure of the shorter annual assessment.

As this report aims to provide relevant background in relation to the specific information needed by ICES to address the request for advice from NASCO, it does not describe all the activities in England and Wales to maintain, improve and develop salmon fisheries. More detailed description of such management actions is provided in the following reports prepared for NASCO since 2007:

- NASCO Implementation Plan for Salmon Management in UK (England & Wales) 2013 to 2018. Available at: [http://www.nasco.int/pdf/2013%20papers/CNL\(13\)46%20FINAL.pdf](http://www.nasco.int/pdf/2013%20papers/CNL(13)46%20FINAL.pdf)
- Annual reports on progress against issues identified in the Implementation Plan. Available at: http://www.nasco.int/implementation_plans_cycle2.html
- Focus Area Report on Management of Salmon Fisheries, 2007. Available at: http://www.nasco.int/pdf/far_fisheries/FisheriesFAR_EnglandWales.pdf
- Focus Area Report on Protection, Restoration and Enhancement of Salmon Habitat, 2008. Available at: http://www.nasco.int/pdf/far_habitat/HabitatFAR_EnglandWales.pdf
- Focus Area Report on Aquaculture, Introductions and Transfers, and Transgenics, 2009. Available at: http://www.nasco.int/pdf/far_aquaculture/AquacultureFAR_EnglandWales.pdf

In August 2008, the Environment Agency published its sea trout and salmon fisheries strategy ('Better Sea Trout and Salmon Fisheries – Our Strategy for 2008-2021') with a goal of "more sea trout and more salmon in more rivers bringing more benefit" (Environment Agency, 2008). The strategy builds on the original 1996 Salmon Strategy, but puts emphasis on improving the environment, as experience has shown that the most significant gains for these fisheries have come from the big and broad environmental programmes. The European Water Framework Directive and the programme of measures under the River Basin Management Plans are integral to delivering this. There is also a greater focus on partnership, reflecting the growth of other bodies such as the various River and Fisheries Trusts who are able to deliver using wider sources of funding. In addition, the strategy recognises the considerable economic and social benefits that come from sea trout and salmon fisheries. At the time of writing, Natural Resources Wales has not produced a specific strategy for its salmon fisheries, but broadly follows the same principles.

The annual assessment report aims to collate and present data from the most recent year as early as possible in the following year. These are initially published as provisional data and are updated and confirmed as complete catch data are obtained and records validated. The Environment Agency and Natural Resources Wales also publish separate Salmonid and Freshwater Fisheries Statistics reports. These are available at:

<https://www.gov.uk/government/collections/salmonid-and-freshwater-fisheries-statistics>.

Cefas, the Environment Agency and Natural Resources Wales would welcome comments or suggestions for improvements to this report and the shorter annual assessment report and associated tables and figures. Contact details are provided on the back cover of this report.

ASSESSMENT OF SALMON FISHERIES IN ENGLAND AND WALES

1. DESCRIPTION OF STOCKS AND FISHERIES

There are 49 rivers in England and 31 rivers in Wales that regularly support salmon (Figure 1), although some of the stocks are very small and support minimal catches; of these, 64 rivers have been designated 'principal salmon rivers'. Conservation limits (CLs) and Management Targets (MTs) (see Annex 7 for details) have been set for the 42 principal salmon rivers in England and 22 in Wales and are used to give annual advice on stock status and to assess the need for management and conservation measures. Organisational structures have changed over time, however salmon data are still compiled and presented separately in the annual assessment for Wales and 7 regions of England (although many of the tables do not include data for the Anglian and Thames regions). The rivers containing salmon that fall into each geographical region are shown in the text table below. There are no salmon rivers in the Anglian region, but this region is included in some tables as it has a small coastal fishery for salmon.

Region	River	Region	River	Region	River	
North East	Aln	South West (cont.)	Fowey	Wales (cont.)	Afan	
	Coquet		Camel		Neath

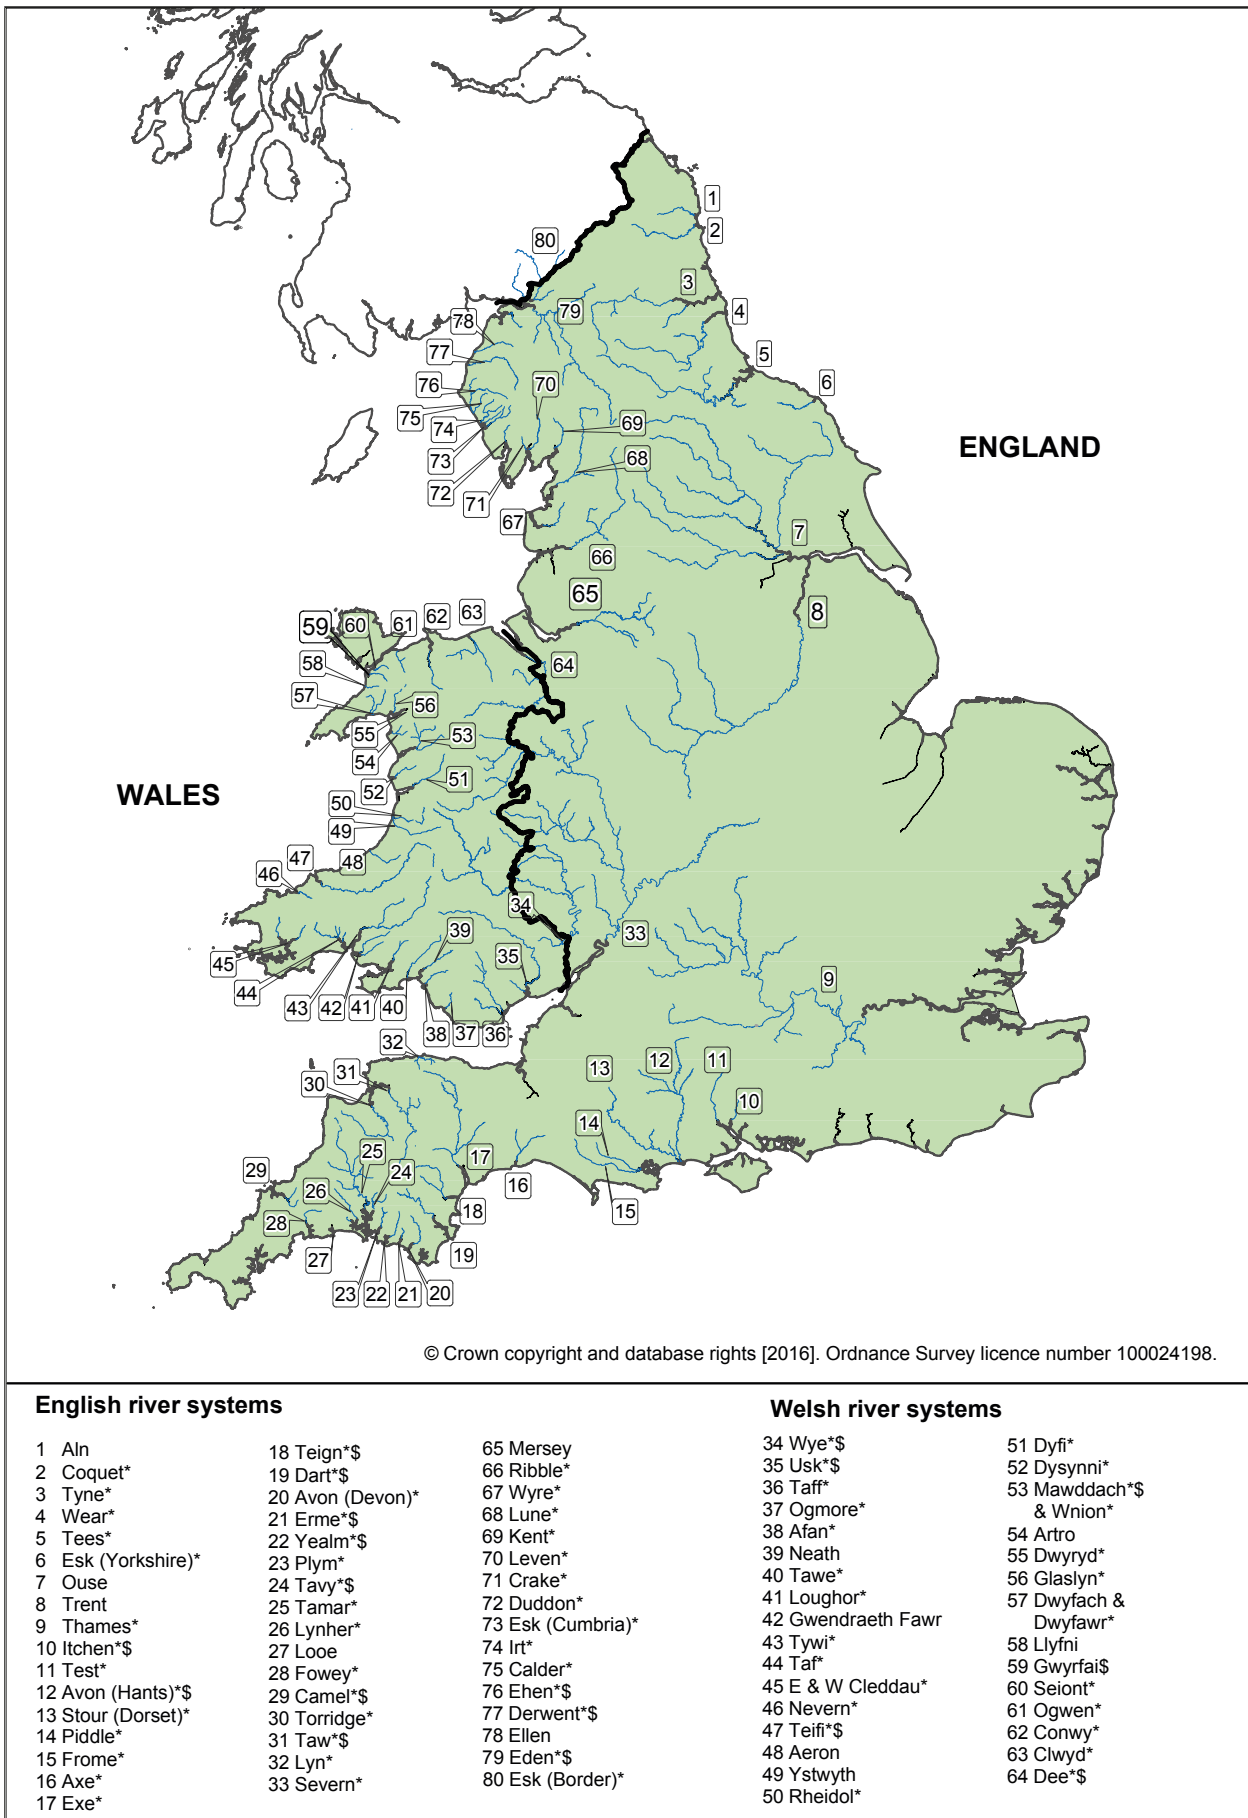

Figure 1. Map of England and Wales showing the main salmon rivers and denoting those with Salmon Action Plans (*) and those designated as Special Areas of Conservation (\$) in which salmon must be maintained or restored to favourable conservation status.

Fisheries in all rivers are subject to the controls described below. Increasingly, actions to improve salmon stocks in England and Wales are being delivered through the EU Water Framework Directive. These actions build on the earlier Salmon Action Plans (SAPs) that were prepared for all the principal salmon rivers and are delivered at catchment level and underpinned by the broader River Basin Management Plans (Section 11.1).

Eighteen rivers have been designated Special Areas of Conservation (SACs), under the EU Habitats Directive 92/43/EEC, with salmon as a named qualifying species. This places an additional requirement on managers to maintain the habitats in these rivers in a favourable condition for salmon. Further details about this and other European Directives and measures affecting salmon management are provided in Annex 6.

There are a large number of different specialised salmon fishing methods employed in England and Wales. These can be grouped into five generic categories: gill nets (which entangle fish), sweep nets (which encircle and trap fish), hand-held nets, fixed engines (a term used to describe various fixed fishing gears) and rods. Brief descriptions of all the various netting methods (including fixed engines) employed are provided in Annex 3.

Rod fishing for salmon is permitted on all rivers supporting salmon stocks. Net or fixed engine fisheries are licensed or authorised to operate on many of the larger rivers/estuaries (26 in 2015); on a small number of these rivers there is currently no active fishing although the potential for fishing to resume remains. There is a policy to phase out coastal fisheries that exploit predominantly mixed stocks where the capacity to manage individual stocks is compromised; the two remaining coastal fisheries for salmon, on the north-east and Anglian coasts, are currently subject to phase-outs.

Details of the various regulatory measures and other factors that limit fishing effort, and how these have changed over time, are provided in Section 2.

2. FISHERY REGULATION MEASURES

2.1 Decision Structure

A decision structure for determining fishing controls on salmon fisheries in England and Wales has been developed to assist in applying fisheries regulations in a logical and consistent manner, and in line with NASCO guidance. This tool focuses on an assessment of the probability of achieving the management objective in five years' time for a given river's salmon stock (the management objective requires that rivers meet their conservation limit in four years out of five, on average). It indicates the level of change in exploitation rate required in order to improve failing rivers, and helps to highlight the need for other management actions where these may be appropriate. The decision structure is applied annually as part of a regular review process when the stock assessment for the fisheries in England and Wales is published. It is also used when existing regulations (Net Limitation Orders and byelaws) are reviewed. A schematic representation of the decision structure is provided at Annex 7.

While the primary management objective is to ensure the conservation or restoration of stocks, socio-economic factors may be taken into account when new management measures are considered. This may influence the nature and balance of controls affecting different stakeholder groups and the rate of stock recovery that is planned (Annex 7). Further details are available in the NASCO Implementation Plan for Salmon Management in UK (England & Wales) 2013 to 2018: [http://www.nasco.int/pdf/2013%20papers/CNL\(13\)46%20FINAL.pdf](http://www.nasco.int/pdf/2013%20papers/CNL(13)46%20FINAL.pdf)

2.2 Licensing, NLOs and Byelaws

Salmon fisheries in England and Wales are primarily regulated by effort controls, which specify the nature of the gear that may be operated, along with where, when and how it may be used. Anyone fishing for salmon with nets, traps or rod and line must have a licence, and numbers of net/trap licences issued are usually limited by Net Limitation Orders (NLOs) that apply to individual fisheries (e.g. within each estuary). A full listing of the NLOs applying to salmon net fisheries in England and Wales is provided in the annual assessment report. A small number of trap fisheries are privately owned and are not subject to NLOs; these fisheries are now referred to as 'historical installations' and their use must be authorised by the Environment Agency (provisions that came into force with the Marine and Coastal Access Act, 2009); this authorisation may have conditions (e.g. catch limits) attached. There is no limit on the number of rod licences that can be issued.

Regulations are applied on a multi-annual basis, usually operating for five to ten years, although with intermediate reviews where these are considered appropriate. This is designed to ensure some stability and continuity in the fisheries, while at the same time allowing new management objectives (e.g. restoring the stock above its conservation limit) to be applied over an appropriate time frame. The heritage status of some net and fixed engine fisheries is now also taken into account when determining appropriate regulatory controls. For example, consideration may be given to retaining a residual fishery and/or permitting a low level of catch. Further details of the approaches used for assessing the heritage value of fisheries are provided in a separate report, available at: <http://webarchive.nationalarchives.gov.uk/20140328084622/https://publications.environment-agency.gov.uk/skeleton/publications/ViewPublication.aspx?id=d7e699e3-20cc-41d9-82fc-add941c283e2>.

Byelaws may be introduced to make reductions in fishing effort in rod and net fisheries (e.g. length of seasons, to control the type of fishing gear that may be used, or where and when fishing may take place). Where there is a justified and serious conservation concern, byelaws can be used to close fisheries. Reductions in licence numbers imposed under NLOs will not necessarily have immediate effect on the number of licences issued, because existing licensees who are dependent upon fishing for their livelihood may retain the right to receive a licence. In some circumstances payments can be, and have been, made to netsmen to temporarily or permanently cease fishing, facilitating more rapid reductions in fishing effort. The Marine and Coastal Access Act, 2009 removed the automatic right to a licence for future NLOs, but provided the power to pay compensation to affected fishermen.

A full listing of the byelaws applying to salmon rod fisheries in England and Wales is provided in the annual assessment report. This includes details of season lengths, method restrictions, mandatory catch and release (C&R), and bag limits.

Many fisheries are subject to local regulatory measures where specific protection is required to conserve stocks. Such measures are regularly reviewed. The recent trend has been for an increase rather than a reduction in restrictions.

2.3 Catch limits

While, historically, there have been no regulations imposing catch limits for salmon net fisheries (with regulation focusing only on effort controls), there has been limited use of catch limits in recent years and the use of such provisions may be extended in future. A full listing of the catch limits currently applying to salmon net and fixed engine fisheries in England and Wales is provided in the annual assessment report.

Consideration is also being given to the possibility of introducing catch limits in the net fishery operating on the north-east coast, with the aim of limiting the relatively high catches that have occurred in some recent years. A concern here is that while the fishery continues to be phased out, the relatively small numbers of remaining netsmen have the potential for markedly improved catch rates (higher catch per unit effort) and for overall catches in this mixed stock fishery to remain high, at least in some years.

For rod fisheries, a number of restrictions have been introduced under local byelaws to limit the numbers of fish taken by individual anglers. Details of the rod bag limits currently in force are provided in the annual assessment report. Although not strictly catch limits, mandatory 100% catch and release has also now been introduced on a number of catchments to aid stock recovery (Section 3.2). It is unclear to what extent the imposition of bag limits may impact on the effort expended by anglers in particular river fisheries, but a preliminary investigation indicated no apparent difference in catch and release rates on rivers with and without bag limits. Non-statutory restrictions have also been introduced in some areas by fishery owners and angling associations, but there is no national record of these.

2.4 Phase-outs, closures and buy-off arrangements

Since 1996, there has been a policy in England and Wales to close coastal net fisheries that exploit predominantly mixed stocks where our capacity to manage individual stocks is compromised. Where this applies, an NLO of zero has been introduced and the number of licences issued has declined as existing licensees retire. Similar phase-outs have also been applied in some

other fisheries where there were particular concerns about stock status. Over recent years, the phase-out of eight small fisheries has been completed and the fisheries closed through byelaw changes; many of these were mixed stock fisheries. A small number of other fisheries have also been reduced to zero nets, but might reopen should stock status improve.

The largest phase-out scheme has operated in the north-east coast fishery. The phase-out began in 1993, immediately prior to which 142 drift net licences had been issued, with higher numbers previously. In 2003, the remaining 69 licensees using drift nets along the coast of Northumberland and Yorkshire were offered compensation, on a voluntary basis, to permanently relinquish their licences. This resulted in the number of drift net licences being reduced to 16 in 2003 (an immediate reduction of 77%). The number of drift net licences has subsequently been further reduced; the latest data are provided in the annual assessment report. The north-east coast fishery NLO was reviewed again in 2012, the final year of the then current NLO. Under new measures, the phase-out of the drift net fishery was maintained for the next 10-year NLO period, with a decision that this fishery should be closed by 2022 when the new NLO expires. The new NLO also extended the phase-out measures to the coastal T & J nets, with the option for maintaining some level of inshore netting to be reviewed in 5 years' time (2017).

The Anglian net fishery is also subject to reduction based on the policy of phasing out coastal fisheries predominantly exploiting mixed stocks, although, in this case, the stocks targeted are primarily sea trout and the nets catch few salmon; typically, fewer than 5 salmon are reported each year.

A number of other net fisheries in England and Wales remain subject to phase-out measures. However, on some rivers recent reviews have led to the replacement of phase-outs with some limited authorisation of continued netting. For example, the phase-out of the Taw/Torridge fishery (formerly South West Region) was replaced with a new NLO in 2012 allowing one seine net to continue to operate and the phase-out on the River Leven (formerly North West Region) was replaced with a new NLO in 2013 allowing the use of two lave (hand-held) nets. Some fishing also resumed on the Rivers Tamar and Tavy in 2014, subject to additional catch limits. In some instances, phase-outs have been facilitated or accelerated by compensation payments. Details of all these recent phase-outs are summarised in the latest annual assessment report.

The policy to phase out coastal salmon fisheries predominantly exploiting mixed stocks has had a major effect on catches. The largest change has occurred in the north-east coast fishery, but there have been reductions and closures of a number of other smaller fisheries also. Although there have been large annual fluctuations in the declared catches, the overall effect of these various measures has been to reduce the catches in mixed stock coastal fisheries from an annual average of about 41,000 fish for the period 1988–1992 to a little under 32,000 for the period 1998–2002 and about 11,700 fish since 2003.

In addition to phase-outs, a number of other effort reductions have also been implemented over recent years, in particular to restrict the available fishing time in some fisheries and through agreements to release fish. For example, netsmen fishing on the Avon and Stour (Christchurch Harbour) and on the Piddle and Frome (Poole Harbour) have previously been compensated to release all salmon caught. The Avon and Stour fishery was closed in 2012, but the release provision for all salmon has continued to apply to the single seine net operating in Poole Harbour. Typically, such measures have been facilitated through compensation payments (buy-offs). Details of all the arrangements to reduce netting effort in the most recent year, and a summary of earlier measures, are provided in the annual assessment report.

2.5 National spring salmon byelaws

In response to a widespread decline in stocks of early-running multi-sea-winter (MSW) salmon in the 1980s and 1990s, it was determined that exploitation of this stock component needed to be significantly reduced. Consequently, the national spring salmon measures were introduced in 1999. Under these measures, netsmen are banned from killing, and in most cases fishing for, salmon before 1 June. However, there are derogations that allow fishing in some areas where netting is predominantly for sea trout, on the basis that any salmon caught are returned alive. For rod fisheries, the national measures ban the killing of salmon caught by anglers prior to 16 June and restrict the methods that they can use at this time to artificial flies or lures. Mandatory catch-and-release was imposed for rod fisheries as an alternative to the closure of fisheries in the early part of the fishing season, aiming to allow continued fishing with minimal loss of stock. The total package of national spring salmon measures was reviewed, consulted upon and renewed for a further 10 years in December 2008.

The introduction of the national measures has had a substantial impact on catches. For net fisheries, the number of fish caught before June has fallen from a 5-year average (1994–1998) of almost 3,000 fish (6.7% of the total catch) to around 60 (0.3% of the catch) since 1999, all of which had to be released. The latter have primarily been taken in a small number of fisheries in Wales, the South West, North East and Anglian Regions (mainly targeted at sea trout) that are allowed to operate prior to 1 June, provided any salmon caught before that date are released.

The national measures have contributed to the increase in catch and release rates in rod fisheries (Sections 2.6 and 4.4) and have also affected catches. On average, pre-June catches, including fish released, comprised 11% of the total declared rod catch in the five years prior to the measures (1994–1998), while this has fallen to a mean of about 6% since 1999.

An analysis of the numbers of salmon released by weight category (<3.6 kg (8lbs), 3.6–6.4 kg (14lbs), and >6.4 kg) and season, for the years since 1998, is included in the latest annual assessment report. This indicates that since the introduction of the national measures to protect spring salmon, anglers have been voluntarily releasing an increased proportion of all fish caught after June, and large salmon in particular.

2.6 Non-statutory restrictions

As well as statutory measures, a range of voluntary measures is in place. These include agreements between angling and netting interests, which result in netsmen being compensated to release fish or not to fish, and extensive voluntary catch and release (C&R) of rod-caught fish.

An Environment Agency review in 2004 identified certain rivers where C&R rates should be increased to protect and enhance stocks. In 2005 a national campaign was undertaken to increase voluntary release rates and provide guidance on best practice for anglers, and a number of Environment Agency Areas wrote to and/or made presentations to anglers and fishing associations to encourage use of C&R. A C&R guide was also circulated to all holders of a full Environment Agency salmon licence in September 2005, highlighting rivers with poor stocks and a low C&R rate. As a result of these measures, a number of clubs introduced bag limits (Section 2.3) and method restrictions.

In more recent years, there have been further efforts to promote C&R by the Environment Agency and Natural Resources Wales and local fisheries groups, some in conjunction with promoting the use of circle hooks. For example, following the introduction of mandatory C&R on the Rivers Wye, Taff & Ely in 2012, further efforts were made to encourage voluntary improvements in C&R on other rivers entering the Severn Estuary where stocks continue to under-perform. Thus, in 2012, the Environment Agency worked with River Usk fishing interests and the newly formed Severn Salmon Anglers Conservation Association to encourage increased uptake of voluntary C&R, particularly towards the end of the season. A leaflet was sent out to as many salmon anglers as possible on the Severn in the autumn of 2012, and a new leaflet and campaign was launched by the Wye and Usk Foundation in 2013, with support from both the Environment Agency and Natural Resources Wales.

Levels of C&R have been further enhanced on some rivers in recent years through negotiated agreements. On the Rivers Test and Itchen (formerly Southern Region) and the Frome and Hampshire Avon (formerly South West Region), the salmon fisheries have reached voluntary agreements for all fish to be released and, in some cases, to make C&R compulsory in their Fishery Association rules. A number of other informal C&R targets have been agreed with fishery associations on other rivers.

In addition, non-statutory restrictions are known to be imposed by some fishery owners and angling associations on methods and fishing areas. However, there is no national record of these. For example, fishery owners on the Rivers Frome and Piddle have discouraged worming on their waters, and in Cornwall, the use of circle hooks continues to be promoted on the Rivers Camel and Fowey, where worm fishing has been responsible for the capture of a high proportion of the salmon rod catch. Fisheries Associations on these two rivers have introduced rules requiring the use of circle hooks from 30 September to the end of the season (15 December), and free hooks have been provided to the main angling clubs by the Environment Agency. Local arrangements also exist on the Hampshire Avon where angling for salmon ceases on days when water temperature (measured at 09:00 at Knapp Mill) exceeds 19°C. Similar arrangements have been in place on the Rivers Test and Itchen since 2013 to restrict angling during periods of high temperature.

2.7 Carcass tagging scheme and ban on sale of rod caught fish

A national byelaw came into effect in England and Wales in 2009 requiring all net-caught salmon and sea trout to be individually tagged with a carcass tag after capture and for the details of all fish caught to be recorded in an annual logbook. A national byelaw banning the sale of rod-caught salmon and sea trout in England and Wales also came into effect in 2009, and the Marine and Coastal Access Act, 2009, extended existing legislation to enable 'handling salmon (and sea trout) in suspicious circumstances' to include 'selling'. These measures were designed to reduce the sale of illegally caught fish and to improve net catch estimates in compliance with international obligations to reduce the levels of illegal and unreported catch (Section 4.6). In tandem with the carcass tagging scheme, the ban on sale of rod caught fish was designed to close a loophole whereby illegally caught fish could be offered for sale, and to discourage a small minority of anglers from killing a significant number of salmon (and sea trout) for sale.

Both schemes have operated successfully since their introduction, with no evidence of significant problems.

Carcass tag (photo courtesy of Steve Williams, Environment Agency)

An initial review of the byelaw provisions relating to both carcass tagging and the ban on sale of rod caught fish (Environment Agency 2010) concluded that the measures had worked well and that there was no need to change the byelaws. Surveys have also indicated a high level of awareness among fishmongers and the wider catering industry, and that the measures were generally supported among the catering trade and by fishermen. Further, anecdotal reports indicate that these measures have significantly raised awareness among those who buy fish, in particular, about the risks they face if they are found to be in possession of 'questionable' fish. Such reports also suggest that the new measures have greatly reduced the incidence of rod anglers taking and selling large numbers of salmon and sea trout; this is supported by evidence of fewer 'back door' sales of fish. Consultation with Environment Agency enforcement officers has indicated ongoing satisfaction with the measures which are regarded as being positive and working well. Surveillance, inspection (e.g. of catering premises) and information gathering activities support this view.

It is impossible to quantify the precise impact of these measures on catches. However, carcass tagging is expected to have resulted in a modest increase in reported catch, while the ban on sale of fish has facilitated the steady increase in C&R rates in rod fisheries. Both measures should also contribute to a simultaneous reduction in the unreported and illegal catch estimate (see Section 4.6).

3. FISHING EFFORT

The licences and byelaw controls described in Section 2 provide overall limits on the 'allowable' fishing effort in England and Wales and are used to regulate both fishing effort and levels of exploitation on migratory salmonids. These have been subject to substantial change over recent years. Although catch limits are increasingly being used, these currently have relatively little effect on the overall fishing effort.

The amount that both netsmen and anglers actually fish (the 'utilised' effort) also varies due to weather conditions, perceptions about the numbers of fish returning, and other factors, such as the increased costs of net licences, fuel and fishing gear and changes in the market price of

salmon (see Section 9.5). Changes in rod licence costs and the imposition of compulsory catch-and-release may also have affected the take-up of licences and effort. Changes in the allowable and utilised effort are discussed in more detail below.

3.1 Allowable effort in net fisheries

The regulatory measures applied to net fisheries provide an overall limit on the 'allowable' fishing effort. There has been a long-term decline in the numbers of licences issued for all types of nets and traps dating back to the 1970s. This marked decline in effort reflects both the measures taken to reduce levels of exploitation (especially in mixed stock fisheries) and the declining commercial viability of some fisheries. While the reduction in the number of licences provides an indication of the extent of recent effort reduction, the actual reduction in allowable effort has often been greater than this as a result of additional restrictions, principally on the amount of time available for fishing. Nevertheless, there may also be potential in some fisheries for fishermen to make more use of the available time when conditions are favourable.

3.2 Allowable effort in rod fisheries

The regulatory controls applying to rod fisheries were summarised in Section 2. The national spring salmon measures, ban on sale of rod-caught fish and catch and release requirements are all thought to have influenced angling effort in recent years. Mandatory catch-and-release now applies on some rod fisheries, including the Rivers Wye, Taff and Ely in Wales and River Leven in north-west England, and bag limits also restrict catch levels on some rivers.

3.3 Utilised effort in net fisheries

Since the late 1990s, netsmen have been required to report effort data along with their catches. In most fisheries this has previously been reported as the number of tides fished, although in the north-east coast fishery and for the fixed engines in the former Midlands and North West Regions effort has traditionally been reported as the number of days fished. Since 2011, revised logbook reporting arrangements have meant that effort data has been available as days fished for all fisheries. Reporting rates for net fisheries have been at, or close to, 100% for many years and latterly this has been reinforced by the requirement for carcass tagging.

These data provide an estimate of the total utilised effort in salmon net fisheries, and data for the most recent year are available in the latest annual assessment report. For those fisheries that mainly target sea trout and which are allowed to fish before June 1 (but which cannot land salmon at this time), the allowable and utilised effort data include this extended fishing period.

There is typically considerable variation between the levels of utilised effort in individual fisheries. It is virtually impossible for most fisheries to utilise 100% of the allowable effort (with the exception of some fixed engines) due to factors such as weather conditions, tide heights and availability of fishing stations. In the north-east coast fishery, for example, it has been suggested that no more than about 75% of the allowable effort could be used in the summer months under typical weather conditions (Anon., 1997). In some recent years, however, when conditions have been favourable (and catches relatively high), it has been possible for the drift nets in this fishery to utilise a higher proportion of the available days.

The overall changes in allowable and utilised effort (expressed in days), and the percentage of available days utilised by netsmen, over the available time series is provided in the annual assessment report. The percentage of fishing days utilised has shown a general decline over much of the period, although there has been a marked upturn in utilised effort in some recent years. This is thought, in large part, to reflect the improved catch in these particular years and suggests that the take-up of available fishing opportunities is strongly influenced by catch rates, although the availability of suitable weather conditions also affects fishing opportunities.

3.4 Utilised effort in rod fisheries

The numbers of salmon and migratory trout angling licences purchased each year (annual and short-term) are provided in the annual assessment report for the period since 1994. No comparable data are available for earlier years because of changes in licensing arrangements. The number of short term (one day and eight day) rod licences issued has shown a gradual decline over the period. The number of annual licences has changed more markedly, decreasing from ~27,000 in 1994 to ~15,000 in 2001 (down 44%), mainly due to the decline in salmon stocks and the introduction of restrictions on angling, especially those to protect early-run MSW fish (compulsory catch and release before 16 June). Licence sales were particularly low in 2001 due to the restrictions on access to many rivers as a result of an outbreak of the 'foot and mouth' livestock disease. Sales of annual licences then increased, reflecting efforts to promote angling and to reduce levels of licence evasion through targeted enforcement, but have fallen again somewhat in the past three years.

Catch returns from licensed anglers indicate where fishing took place, and these data have previously been summarised on a regional basis. While the regional structure of the Environment Agency ceased to apply in 2014, data have continued to be reported in the same way to provide continuity of the time series. Time series of the total rod days fished in each former region are provided in the annual assessment report. An adjustment was made to estimate rod effort for 2015; further details are provided in Section 4.6. The number of days fished by anglers closely followed the reduction in rod licence numbers between 1994 and 2001. However, while annual licence sales subsequently recovered, closer to levels at the start of the time series, the number of days fished by anglers did not. The number of days fished has fluctuated somewhat from year to year since this time, but without any obvious trend.

As indicated in Section 2.5, the national measures for rod fisheries introduced in 1999 banned the killing of salmon by anglers prior to 16 June and restricted the methods they can use at this time to artificial flies or lures. Mandatory catch-and-release was also imposed for this period. The apparent decrease in average annual rod fishing effort between 1994 and 1998 (the 5 years prior to the national measures) and subsequently is thought, in part at least, to reflect this change. Surveys suggested around 20% of the overall angler effort took place prior to 16 June, although there was substantial variation between regions. Expressed as a percentage of all the days fished early in the season in England and Wales, the highest fishing effort before June 16 consistently occurred in Wales and may reflect early season fishing targeted at sea trout rather than salmon.

Fishing effort data (days fished) submitted via the licence returns do not distinguish between times spent fishing for salmon and sea trout separately. This information is important for developing procedures to estimate angling exploitation rates, which are used on rivers without traps or counters in the assessment of compliance with conservation limits (see Annex 7).

Surveys conducted in 1992 and 2006 indicated that around a quarter (28% and 26%, respectively) of angler effort nationally was then directed at sea trout only (see text table below). Effort directed at sea trout appears to have been a little more consistent across regions in 1992 (range 24 to 34%), compared with 2006 (18 to 36%). In both years, the highest sea trout effort was reported for the former South West Region (35%, on average, for the two surveys); there are no clear differences among the other regions, where average effort directed at sea trout is around 25%.

Percentage of rod effort (night and day combined) targeted at sea trout, based on questionnaires sent to anglers in respect of the 1992 and 2006 seasons.

Previous EA Region / NRW	1992 survey	2006 survey
North East	29	18
Southern	29	27
South West	34	36
Midlands	–	–
North West	29	18
Wales	24	35
Total	28	26

4. DECLARED CATCHES

4.1 Catch reporting arrangements

Catches of salmon (and sea trout) by nets and fixed engines are derived from data reported in the mandatory catch returns (logbooks) submitted by licensed netmen. There is typically full compliance with the submission of catch returns by netmen (i.e. a 100% return rate), although there are some uncertainties as to the reliability of the reported catches. The principal concern, supported by evidence where observed catches have been compared with those reported, is of under-reporting of catch. However, the possibility of over-reporting has occasionally been proposed, for example, prior to a possible buy-out agreement. Undeclared and illegal catches are discussed further in Section 4.6. To help address concerns about the reliability of catch return data, and in response to international obligations to reduce the levels of illegal and unreported catch, a carcass tagging scheme was introduced in England and Wales in 2009. Under this scheme, all net-caught salmon and sea trout must be individually tagged with a carcass tag after capture and the details of all fish caught recorded, along with the tag number, in a logbook. These measures are expected to improve the reliability of declared catch data for net fisheries since each net-caught fish must be tagged and each tag must be accounted for. Since implementation, the carcass tagging and logbook scheme have been subject to minor changes to help improve operation, but are considered to have been a success in both reducing illegal catches and improving the reliability of catch data.

Information on catches of salmon and sea trout by anglers also relies on catch returns. However, while the submission of a return is a legal requirement (including nil returns), in practice rod catch return rates never reach 100%. Levels of reporting were typically lower at the start of the available time series (1950s) and progressive efforts have been made to improve levels of reporting since this time. The issue of undeclared and illegal catches, and how catches are corrected to account for these, is discussed further in Section 4.6.

A national rod catch return system has operated in England and Wales since 1992 in order to maximise the quantity and quality of catch returns received; catch data are stored on a national rod licence database for England and Wales maintained by the Environment Agency (including on behalf of Natural Resources Wales). This, together with other changes in rod licence administration, has generally facilitated better catch reporting in line with NASCO recommendations to reduce the level of unreported catch. For example, licences have been issued electronically since 2005 to provide a more up-to-date and accurate database for issuing reminders. Since 2014, anglers have also been able to provide their catch return on-line and greater reliance was placed on this method of data capture in 2015. One aim of these changes has been to help ensure more timely and accurate catch return data. However, concerns have been raised about the completeness of the data for 2015 with possible links to the (new) on-line reporting system. These concerns are under investigation, but to provide declared catch data for 2015 comparable (in terms of reporting rate) to recent years an additional adjustment for under-reporting has been applied (see Section 4.6).

National catch reminders, covering as many anglers as possible, were first issued in January 1995 (for the 1994 season); some regional reminder schemes had operated previously. The reporting and reminder system was initially subject to a number of difficulties, but was improved in 2001, enabling more effective targeting of reminders (for example, reminders were sent out earlier - in November - closer to the end of the fishing season in most regions). The system has been modified since, including the issue of targeted second reminders to anglers who failed to send in a return. Since 2010, this second reminder has been sent by email rather than by post, resulting in a reduction in coverage (due to some anglers not having an email address).

A ban on the sale of rod-caught fish was introduced in 2009, at the same time that the carcass tagging scheme came into force for the net fisheries. Since this time, the sale of illegally caught fish is expected to have become substantially harder and this, in turn, is expected to have reduced the illegal catch of fish.

The percentage of salmon rod licence holders making a catch return increased in 2001 and 2002 when the new reporting and reminder arrangements were first introduced. Typically, at that time, around 85% of annual licence holders submitted a return, while the proportion of short-term licensees making a return was usually around 55%. It is known that many anglers who purchase more than one short-term licence during a season combine catch details on a single licence return, and this contributes to the lower return rate for this licence category. Also, in general, short-term licence holders fish less and catch fewer fish than those anglers who hold an annual licence. A detailed analysis of catch return data for 2002 for the Rivers Dee (North Wales) and Tyne indicated that 89% and 86%, respectively, of short-term licence holders making a return declared a nil catch, and that 98% and 96%, respectively, of the total declared salmon catch for these rivers was made by anglers holding an annual licence. The lower return rate for short-term licence holders is, therefore, expected to have a negligible impact on the declared catch. It is understood that many of the annual licences for which no catch returns are received are typically held by junior season licence holders. These anglers are believed to fish rarely for salmon, and under-reporting of catches from this source is believed to be minimal.

For a small number of rivers, typically the River Wye in Wales and the Rivers Test and Itchen in the former Southern Region, fishery owner's returns have previously been used to derive rod catches as these were considered more complete than anglers' returns. However, in an effort to standardise and to encourage improved reporting rates, only the declared catch data have been included in the annual assessment report since 2012.

4.2 Catches for the latest assessment year

The annual assessment of stocks and fisheries is carried out early in each year so that data can be collated and analysed in time for the annual meeting of the ICES North Atlantic Salmon Working Group, which normally meets in late March / early April. The salmon catch data available at this time are always deemed provisional. The data for nets and fixed engines are usually based on complete returns from netsmen and only require final validation. These data are thus typically subject to little, if any, subsequent change. Rod catch data on the other hand are not usually complete, and are based upon those returns received up until an agreed cut-off date, usually in late February. While these data are largely complete, they are usually subject to some revision as a result of the inclusion of late returns and final checking.

It should thus be remembered that the data for the latest year presented in the annual assessment are provisional and likely to change slightly once all the catch returns are processed and the data validated. Final confirmed data for the latest year are reported in the Environment Agency and Natural Resources Wales annual compilations of catch data, which are published later in the year (see, for example, Environment Agency, 2014a). Updated final figures for the latest year are also included in the next annual assessment report.

The provisional salmon catches for England and Wales by both nets and fixed engines and rods for the latest year are provided in the annual assessment report, together with available time series. These data provide both regional and national totals.

4.3 Catches in coastal, estuary and river fisheries

ICES requests that catch data (fish caught and retained only) are grouped by coastal, estuary and river fisheries. Relevant data for England and Wales for all years since 1993, including a list of all the fisheries included in the different categories, are presented in the annual assessment report. The catch for the coastal zone mainly reflects the catch in the north-east drift and fixed net fishery, but also includes drift nets on the Cumbrian coast (formerly North West Region) until 2003, and a number of nets and fixed engines fished around the Welsh and East Anglian coasts and in the Bristol Channel (Severn Estuary). In recent years, only two coastal fisheries have remained in operation, and one of these, Anglian, takes very few salmon. The river fisheries comprise catches in freshwater and represent the total rod catch (fish retained) plus the very small catches in two ancient fixed engines, the River Conwy basket trap (last fished in 2002) and River Eden coops (not fished in 2006 due to flood damage, but back in operation from 2007). The estuary category includes all other net and fixed engine fisheries.

A range of factors influence the relative proportions of fish taken in different areas, but the principal influences on these changes have been the national byelaws protecting early-running MSW salmon introduced in 1999, the increasing prominence of C&R, the phase-out of net fisheries generally, and the partial buy out of the north-east drift nets from 2003. Catches (declared fish caught and retained) in each of the categories have, therefore, been subject to downward pressures over recent years, in the case of the coastal and estuary categories due to the substantial reductions in fishing effort (Sections 2 and 3), and, in the case of river (rod) fisheries, due to the increasing use of C&R (Section 4.4).

4.4 Catch-and-release (C&R)

There has been increasing use of C&R by salmon anglers in England and Wales in recent years. This is in part a result of voluntary measures, but also reflects the legal requirement brought in to protect early-running MSW salmon initially in 1999. It was also reinforced by the introduction of mandatory C&R on some rivers, such as the recent requirement for 100% C&R for the Rivers Wye, Taff and Ely and similar existing measures in the previous North West Region (Section 3.2). Details of the numbers of fish subject to C&R for each of the former regions in England and for Wales is provided in the annual assessment report; these data extend back to 1993 when information on C&R was first recorded. There has been a continued steady increase in the C&R rate over the period. C&R data for each major salmon river in England and Wales are published in the separate annual catch statistics reports produced by the Environment Agency and Natural Resources Wales.

The use of C&R is aimed at increasing the number of fish surviving to spawn and thus helping rivers to meet their conservation limits and achieve long-term sustainability. Such improvement is expected to benefit stocks and thus catches. However, the extent to which C&R directly affects catches is unclear. It is not known how many of the fish caught and released by anglers in any year may subsequently be recaptured one or more times. Further, there are uncertainties about the nature of the relationship between stock size and catch.

Initial results from an ongoing investigation on the River Dee, started in 2007, have provided some information on the 'second' recapture rates for rod-released salmon. In this tagging study, the rates of second capture for rod-released salmon have been highly variable between years (0-18%), but have averaged close to 7%, around a third of the initial capture rate of 21%.

It is unclear what effect C&R has on declared catches. However, in a scenario where:

- (i) fish experienced an initial rod capture rate of 15% (in line with the general average exploitation rate for rivers in England and Wales);
- (ii) the C&R rate was 100%;
- (iii) the rod capture rate for released fish was half the initial or subsequent capture rate; and
- (iv) no fish were caught more than three times;

then, for every 1,000 fish entering the rod fishery, 150 would be caught at first capture, ~11 at second capture and ~1 fish at third capture. Thus the total catch of ~162 fish would be 'inflated' by recaptures of released fish by only around 8%. This is a relatively small amount and so would be of little concern, for example, as a source of error in estimating spawning escapement from rod catches.

This concern would be lessened for rivers with average exploitation rates less than 15% (typically, around a third of counted rivers) or where C&R rates were less than 100% (most rivers).

Of more concern would be rivers where underlying exploitation rates and C&R rates were high; and/or where capture rates for released fish were greater than half the initial capture rate. For example, repeating the above scenario with an initial rod capture rate of 30% and 100% C&R would result in a total catch of around 350 fish inflated by ~16%.

Further assessment of scenarios such as the above is required to gauge the likely impact that the recapture of released fish is likely to have on total stock estimates across the full range of rivers.

4.5 Long-term catch trends

The annual declared net and fixed engine catch for England and Wales over the available time series, since 1956, is available in the annual assessment report. This distinguishes the catch taken in the north-east coast fishery – which increased rapidly in the late 1960s with the introduction of synthetic nets and has comprised well over 50% of the total net catch in most subsequent years – from the catches elsewhere. Although this fishery is currently being phased out and catches have been much reduced, catches in other regions have fallen more quickly. The catches in the other net fisheries have been declining since the mid-1980s, reflecting reductions in both fishing effort (Section 2) and stock sizes.

The annual declared rod catch of salmon over the same time period is also provided in the annual assessment report. From 1993, this distinguishes fish that have been caught and released from those caught and retained. The former now comprise a relatively large proportion of the catch and it is unclear to what extent fish may be caught and recorded more than once (see 4.4 above). Reporting rates are also known to have improved substantially later in the time series.

4.6 Undeclared and illegal catches

The national catch data required by ICES for assessment purposes has to be adjusted to allow for undeclared and illegal catches. The following sections outline the approaches used. The most recent estimate of non-reported and illegal catch for England and Wales is included in the latest annual assessment report.

Unreported catch: All licence holders are required to provide the Environment Agency and Natural Resources Wales with details of their catch of salmon and migratory trout and the number of days fished on each river or, for nets, each fishery. However, a minority of people fail to submit a return, and returns that are made may be inaccurate or incomplete. Efforts are therefore made to correct for these factors. In practice, catch returns are received from 100% of net and fixed engine licence holders and usually from ~70+% of full season anglers – the latter accounting for the majority of fish caught in a catchment, typically 96-98% (see Section 4.1). The main correction for under-reporting is therefore currently made in respect of perceived inaccuracies in the returns.

There are few independent measures of under-reporting in the rod fishery, but these indicate that the level is currently small. Since changes to the licensing and catch return systems were introduced in England and Wales in the early 1990s, a value of 10% of the declared catch has

generally been applied for correction purposes based on the method of Small (1991). Historically, under-reporting was a much more serious problem and varied with each Region, and higher correction factors were used.

Assessment of catch data for the 2015 report identified potential data reporting/accuracy issues thought to be mainly associated with changes to the on-line rod catch reporting system. Analyses were undertaken for a number of rivers around the country where data were available to compare the difference between declared and independent catch records for 2015 with the difference between these same data sets over the preceding 5-year period (2010-2014). This indicated that catches in 2015 showed greater discrepancy compared with previous years, suggesting an increased level of under-recording. Further analysis has determined that this is unlikely to be due to changes in the percentage of rod licence returns received by the Environment Agency. To address under-reporting in 2015, a correction factor (x1.24) was derived based on these analyses. This correction factor was applied to declared rod catches in all regions to produce an (adjusted) declared rod catch comparable (in terms of catch declaration rate) to catches in recent years. A similar adjustment was applied to the rod effort data (days fished). This issue continues to be investigated and provisional data will be revised should further information become available.

For the net fishery, a figure of 8% has been used in recent years to adjust for the level of under-reporting, based on the outcome of surveillance operations. The level may have been substantially higher in the past in certain fisheries, possibly as much as 50%. However, following the successful introduction of logbooks and a carcass tagging scheme in 2009 (Section 2.7), there is now considered to be minimal under-reporting in net fisheries. A figure of 2% was assumed in 2009 and has continued to apply since this time.

Illegal catch: The illegal catch, by its very nature is difficult to quantify. A questionnaire survey of Environment Agency enforcement staff in 1998 indicated that an average value of around 12% of the declared catch was appropriate. The introduction of the carcass tagging scheme and ban on the sale of rod caught fish is expected to have made it substantially more difficult to dispose of illegally caught fish (Section 2.7), and a value of 6% was assumed in 2009 and has continued to apply since this time.

Net seized net from the River Afan, SW Wales (photo courtesy of Natural Resources Wales)

Actions: In order to maintain the low level of under-reporting in the rod fishery the Environment Agency usually issues reminders to anglers that they should record and report their catch. Enforcement action has previously been used when there has been significant contravention of the law requiring reporting of catch. Targeted enforcement activity also aims to suppress illegal unreported catch. A detailed report on illegal and under-reported catches was submitted to a special session of the 2007 NASCO meeting. Full details are available at:

[http://www.nasco.int/pdf/2007%20papers/CNL\(07\)26.pdf](http://www.nasco.int/pdf/2007%20papers/CNL(07)26.pdf)

4.7 Other sources of non-catch fishing mortality

Non-catch fishing mortality includes all sources of mortality generated directly or indirectly by fishing which are not included in the recorded catch. It includes the illegal and unreported catches discussed above in addition to losses of fish that are removed from fishing gear by predators, dead fish that fall out of a net and fish that escape or are released but subsequently die.

The extent of the likely losses will vary between fisheries because of the type of gear used and its method of operation. In addition, the impact of predators, particularly seals, varies between areas.

In most net fisheries in England and Wales, the netsmen remain with their gear and remove any fish caught quite quickly; thus relatively few fish will drop out and losses to predators can usually be limited. Sweep and hand-held nets cause very little damage to the fish and so losses of fish that escape are likely to be minimal. However, small losses may occur from enmeshing (gill) nets, and predation losses may be significant in the north-east coast and Anglian net fisheries, which are close to large grey seal colonies.

No data are available on the mortality of salmon incurred during normal angling activities (e.g. due to lost or foul-hooked fish that subsequently die) that are not recorded in the retained catch. Whilst the use of C&R (Section 4.4) is likely to result in some fish dying through exhaustion or damage, studies have demonstrated that if fish are appropriately handled, mortality following capture is low and a large proportion of fish survive to spawn (Webb, 1998a,b; Whoriskey *et al.*, 2000). Radio-tracking studies carried out by the Environment Agency on the River Eden, Cumbria, found that upwards of 85% of released spring salmon can reasonably be expected to survive to spawn (Environment Agency, 2003a). A study in Cornwall, where a high proportion of the total salmon rod catch on some rivers is taken by worm fishing, also indicated that fish caught with circle hooks were more likely to be hooked in the mouth, and this has been shown to reduce post-release mortality rates by approximately 50% (Cooke and Suski, 2004); all anglers in this area are therefore being encouraged to use these hooks. In order to increase the survival of rod caught fish, the use of tailers was made illegal in England and Wales under the Marine and Coastal Access Act 2009. Although in relatively infrequent use prior to this, tailers were considered to have an adverse effect on salmon survival following C&R.

Projected climate change scenarios for England and Wales (Hulme *et al.*, 2002; Murphy *et al.*, 2009) in the coming decades are of concern since the hotter, drier summers predicted will result in salmon being under greater stress. This may require C&R policies to be reviewed.

4.8 Age composition of catches (nets & rods)

The annual salmon stock assessments conducted by ICES are conducted on two separate stock components: those fish that mature after one winter at sea (i.e. one-sea-winter fish / 1SW or grilse) and those that mature after two or more years at sea (i.e. multi-sea-winter / MSW fish). It is therefore important to be able to assess the relative contributions of different sea-age groups to net and rod catches.

Nets

Prior to 2001, it was not possible to estimate the proportions of 1SW and MSW salmon in the catch of all net fisheries, because netmen were generally not required to report the sizes of individual fish caught, and few scale samples were collected. However, data collection procedures for fisheries in most parts of England and Wales were standardised in 2001 and this permitted age composition of catches to be reported. For fish caught in the north-east fishery, there has been a long-standing methodology for reporting catch by weight category.

Catches in most net fisheries are now reported as small (<3.6 kg = 8 lb) or large (>3.6 kg) salmon, and this can be used as a rough indication of sea-age, the smaller fish typically being 1SW salmon (grilse) and the large fish MSW salmon. Inevitably, however, such a simple weight split will ignore potential differences between years, different stocks or over the duration of the run and will result in some fish being wrongly classified. A summary of the weight split data for net and fixed engine fisheries, based on former regions, is included in the annual assessment report. The estimated proportions of large (MSW) salmon in regional net catches over the available time series is also provided.

Rods

Monthly age-weight keys have been available for salmon caught in the River Dee trap since 1992, and the latest key has been used to estimate the age composition of catches for selected principal salmon rivers in the latest assessment year, and are provided in the annual assessment report. These estimates were derived from the declared catches available at the time the assessment was completed, for fish where weight data were also provided, and should be regarded as provisional.

Summaries of the estimated proportion of MSW fish caught in different rivers and estimated numbers of 1SW and MSW salmon in regional rod catches, over available time series, are also provided in the annual assessment report.

4.9 Origin of fish caught (salmon from other countries / farmed & ranched fish)

As discussed in Section 4.10, many of the salmon caught in the English north-east coast fishery are returning to rivers in Scotland. There is also likely to be some capture of Scottish origin fish in north-west England, in particular, in fisheries operating in the Solway. However, there will equally be small numbers of fish of English origin taken in fisheries operating in south-east and south-west Scotland. Such mixing of stocks in fisheries has been demonstrated by previous tagging programmes and more recent genetic studies, but is typically considered to be of limited extent for most current fisheries.

There are very few other records of tagged salmon released in, or originating from, rivers in other countries being taken in English and Welsh fisheries in the past. No such tag recoveries have been reported in recent years.

There is no salmon ranching in England and Wales. However, fish farm escapees from other countries can sometimes occur (Milner & Evans, 2003). A sampling programme was initiated by Cefas and the Environment Agency in 2003 to identify any salmon suspected of being of farmed origin in the England and Wales catch and to determine the extent to which such fish may be contributing to spawning stocks. This programme operated for four years, but no farmed fish were identified and the programme has been discontinued. Net catches are now much reduced and there is currently no formal mechanism for monitoring fish farm origin fish or any requirement for fish farm escapees to be recorded in catches. However, previous experience indicates that anglers and netsmen would be quick to identify and report such fish should they appear in catches. There have been no such reports in recent years.

Very occasionally, non-native pink salmon have been reported in the UK, and a small number of such fish were caught in 2015. These occasional stray fish are believed to originate from what are now established populations of pink salmon in northern Russia; similar captures are recorded in other countries around the north-east Atlantic. Pink salmon have a strict two-year life-cycle, so tend to establish distinct odd and even-year populations. The introduction in the Russian Federation is believed to have resulted primarily in the establishment of odd-year populations, and this probably explains why strays only seem to be reported here in odd years (e.g. there have been earlier reports of pink salmon in the UK in 2007 and 2011).

4.10 Assessment of national catch trend

Each year, the ICES North Atlantic Salmon Working Group makes an assessment of the status of the salmon stocks in the North East Atlantic as a basis for advising managers (e.g. ICES, 2016). Further details on this assessment are provided in Section 8.4 and Annex 5. This assessment endeavours to provide our best interpretation of what the available catch and effort data tell us about changes in the status of total national stocks of salmon over the past four to five decades.

The starting point for this assessment is the best available time series of nominal national catch data (i.e. fish retained), taking account of non-reported and illegal catches. For England & Wales, nominal catches have been derived from the catch returns submitted by netsmen and anglers and split into 1SW and MSW categories using two different methods. Over the period since 1992, monthly age-weight keys derived from salmon caught in the River Dee trap have been used to estimate the age of all rod-caught fish where a weight and date of capture have been provided. This has then been scaled up to the total catch (rods and nets combined) on a pro-rata basis. In earlier years (1971-1991), the age composition of the total catch has been estimated using the mean weight of the fish caught and the mean weight of 1SW and MSW salmon recovered in tagging programmes. Estimates of unreported and illegal catches have been made on the basis of consultation with fisheries personnel and according to the approach described in Section 4.6.

As the contribution of farmed and ranched salmon to the national England and Wales catch is negligible (see Section 4.9), the occurrence of such fish is ignored in the assessments of the status of national stocks. However, a large proportion of the fish taken in the north-east coast fishery are destined for Scottish rivers, and these are deducted from the catch for England and Wales and added to the returning stock estimate for Scotland in the ICES assessment. This proportion is estimated to have declined from 95% of the north-east net catch in the early part

of the time-series to 75% in the late 1990s and to around 65% since 2003. This reflects both the steady improvement in the status of the stocks in north-east England and the substantial buy-out of drift nets in 2003; the phasing out of these nets having started in 1992 (Section 2). The latter resulted in a major overall reduction in the fishery, with the majority of the remaining netsmen now fishing close inshore using T- or J-nets. Previous tagging studies have shown that these inshore nets exploit a much higher proportion of local fish (Anon., 1991). A genetic investigation of salmon caught in the north-east coast fishery in 2011 confirmed that the current estimates of the relative proportions of English and Scottish fish caught in the fishery are reliable (Gilbey *et al.*, 2012).

The current best estimate of the total catches of 1SW and MSW salmon in England and Wales, for the period since 1971, is available in the annual assessment report. The data indicate that catches of salmon in England and Wales (fish caught and killed only) have declined by over 85% from the early 1970s to the present time. It is also apparent that there was a marked decline in catch around 1990, which is consistent with the general perception of a decrease in the marine survival for many stocks around the North Atlantic at about this time.

5. CATCH PER UNIT EFFORT (CPUE)

Catch levels are influenced by factors such as stock abundance, the catchability of the fish, and by the variation in the time anglers and netsmen spend fishing. Catch per unit of fishing effort (CPUE) is, therefore, used as well as the declared catch in order to help evaluate the relative status of stocks. CPUE can also provide an index of angler satisfaction (people would like to spend less time, on average, to catch each fish), and indicates changes in the profitability of net fishing, the income from the catch being set against the costs of time spent netting. For net fisheries in England and Wales, CPUE data (based on the former regional structure) have been collated using the number of tides fished (or for the north-east coast fishery the number of days fished) as a measure of the amount of fishing undertaken by each licence holder. Rod CPUE data (catch per licence day fished) are now reported for all major salmon rivers in England and Wales in the annual catch statistics reports (e.g. Environment Agency, 2014a).

It should be noted that CPUE values only reflect the availability of salmon during the fishing season and may bear less relation to spawning escapement of fish migrating into rivers after the season closes in November and December. For both net and rod fisheries, the relationship between CPUE and salmon abundance can be influenced by confounding factors (e.g. river flows and altered angling practices). It should also be remembered that net and rod fisheries operate sequentially (the net fisheries exploit the returning fish first), and over different time periods (fishing seasons). Rod fisheries are active over a longer period and typically extend into the early autumn after net fisheries have ceased to fish. Thus, changes in patterns of run-timing may also impact on CPUE values in the different fisheries.

5.1 CPUE in net fisheries

Time series of CPUE data, starting in 1997, for regionally aggregated net and fixed engine fisheries are provided in the annual assessment report. In order to ensure comparability and provide a consistent time series, annual mean CPUEs are only provided for fisheries that have fished in the same way over this period. Fisheries are excluded that have been subject to measures to reduce fishing effort, or which have been subject to other regulatory controls (e.g. a cap on the allowable catch). The number of fisheries represented in this time series is thus subject to change year on year and has reduced over time.

5.2 CPUE in rod fisheries

Summaries of rod CPUE (expressed as number of salmon caught per 100 days fished), aggregated according to the former regional divisions, are also provided in the annual assessment report. The data for the most recent year are based on incomplete returns and should be regarded as provisional. These CPUE time series include returns from a wide variety of anglers (e.g. locals who fish regularly, holiday anglers and those who fish primarily for sea trout) and river types. This will result in the CPUE for salmon varying between regions, but still provides scope for comparisons through time within a region. It should be noted that reductions in effort due to the national measures to protect spring salmon may have affected CPUE from 1999 onwards.

Available evidence from selected rivers where we have estimates of returning stock size, as well as CPUE, suggests rod CPUE values provide a reasonable indicator of stock abundance.

6. EXPLOITATION RATES

6.1 Homewater exploitation

The relationships between salmon run and catch are mediated by fishing effort and catchability (the proportion of the stock taken per unit of fishing effort), which in turn are shown to vary between and within rivers. One prime cause of this variation is likely to be river flow, which acts by influencing the behaviour and availability of the fish to both nets and rods, and also angler activity (Section 9.2). Changes in run timing may also be a factor (Section 7.4).

Relatively few rivers have independent measures of run size to compare against catch. However, such data obtained from counters and traps are available for some rivers in England and Wales and have been used with the total catch (retained and released combined) to estimate exploitation rates. Both the counts and exploitation rate data are provided in the annual assessment report. The rod exploitation rate estimates often show varying trends, but the 'true' exploitation rates (i.e. fish retained) show a marked decline in most rivers over the available time series, an effect largely attributable to C&R, which, over the past 20 years, has increased from 10% to almost 80%. For many net fisheries, exploitation rates have declined due to reduced levels of fishing.

A previous analysis of data from seven rivers (Test, Itchen, Frome, Tamar, Fowey, Dee and Lune; Milner *et al.*, 2001) has shown that, while exploitation rates tend to differ between rivers, there is also considerable variation between years within individual rivers. From a tagging and recapture programme on the River Dee, it has been shown that early season entrants to the river (predominantly MSW salmon) are generally subject to higher exploitation than those entering later.

Since changes to regulatory measures occur frequently in salmon fisheries, with the explicit aim of changing exploitation rates, these need to be taken into account when interpreting historical catches in terms of indicating stock abundance.

6.2 Assessment of national trend in exploitation

As indicated in Section 4.10, ICES makes an annual assessment of the status of stocks in the North East Atlantic over the past four to five decades, based on our best interpretation of what the available catch and effort data tell us about changes in the status of national stocks (see Section 8.4 and Annex 5).

The national assessment first estimates the numbers of salmon returning to freshwater in each country, and then back-calculates the numbers of fish that must have been alive in the sea to generate these returns. This is known as the pre-fishery abundance (PFA). The numbers of returning fish are estimated using the nominal catch data for each country (i.e. fish retained), raised to take account of non-reported catches and exploitation rates for 1SW and MSW fish. The process of deriving a national catch trend was described in Section 4.10. These data then need to be adjusted by national exploitation rates to estimate numbers of returning fish. Each country therefore needs a time-series (beginning in 1971) of exploitation rates for 1SW and MSW salmon.

Times series of exploitation rates for a number of monitored fisheries in England and Wales, referenced in Section 6.1 above, are provided in the annual assessment report. National exploitation rates have been estimated by deriving time-series of 'standard fishing units' employed in the salmon fisheries for the period 1971 to the present. For the period 1971 to 1997, these were calculated from the numbers of net, fixed engine and rod licences issued weighted by their relative catching power, which was estimated from historic CPUE data. For the period 1998 to the present, they are calculated from the numbers of days fished by different net categories (and rod licence numbers) weighted in the same way. The annual exploitation rates are then estimated by referencing the number of 'standard fishing units' employed over the two periods relative to average age-specific exploitation estimates derived for the 1997 and 1998 seasons.

The overall trends in national exploitation rate derived from the above process are also provided in the annual assessment report. These indicate that exploitation rates have fallen from about 50% for 1SW fish and 35-40% for MSW fish at the start of the period to 15% and less than 10%, respectively, in recent years due to the measures taken to control both legal and illegal fisheries. The decline in exploitation rates occurred particularly in the 1990s, but has levelled out more recently.

6.3 Exploitation in fisheries outside England and Wales

Salmon originating from rivers in England and Wales have been exploited in a number of fisheries other than those operating under the jurisdiction of the Environment Agency and Natural Resources Wales within national waters. These include the distant-water fisheries at Faroes and West Greenland, and other fisheries such as those that have operated off Ireland and in other parts of the UK. Tagging studies have provided information on the levels of exploitation for English and Welsh stocks in many of these fisheries and this is summarised briefly below.

West Greenland

This fishery exploits only salmon that would have returned to Europe and North America as MSW fish. The exploitation rates on the MSW component of English and Welsh stocks in the late 1980s/early 1990s were estimated to be in the region of 10 to 20% when catches at West Greenland were in the range of 300 to 900 t (Russell and Potter, 1996). However, following significant quota reductions and other initiatives since the late 1980s, exploitation of MSW fish is believed to have fallen to very low levels. Since 1998, with the exception of 2001 and 2002, the catch at West Greenland has been restricted to that amount used for internal subsistence consumption in Greenland, which in the past had been estimated to be about 20t. However, since that time the catch has increased progressively. Nonetheless, since the majority of fish currently taken in the fishery are of North American origin, exploitation of English and Welsh stocks is expected to remain minimal (<1%). The regulatory measures agreed by NASCO in respect of the West Greenland salmon fishery from 1984 to date are provided in Annex 4.

Faroes

The Faroese fishery exploits both grilse and MSW salmon of largely northern European origin (i.e. not from England and Wales). No quota has been set for this fishery since 2001, and the fishery has not operated in this period. The Faroese authorities have indicated an intention to manage any salmon fishery in a precautionary manner on the basis of the advice from ICES regarding the status of the stocks and with a view to sustainability, taking into account relevant factors such as socio-economic needs. Few tags of English and Welsh origin were recovered in this fishery when it operated, and estimated exploitation rates on English and Welsh stocks at this time were very low (~1%) (Russell and Potter, 1996). The regulatory measures agreed by NASCO in respect of the Faroese salmon fishery from 1984 to date are provided in Annex 4.

Ireland

The Irish coastal drift net fishery, which used to exploit salmon from stocks in England and Wales, closed in 2007 and exploitation of these stocks has effectively ceased. Earlier smolt tagging studies carried out by Cefas and the Environment Agency demonstrated that salmon from all parts of England and Wales were previously exploited in the fishery, but that levels of exploitation varied between stocks from different regions and from year to year. Exploitation rates were higher in the period before 1997, but declined following the introduction of management measures in the Irish fishery in 1997 and subsequent additional restrictions on catches (e.g. TACs) from 2002. In the latter years of fishery operation (1997-2006), exploitation of salmon from north-east England in the Irish fishery was estimated to be negligible (<1%), exploitation on stocks from north-west England and north Wales was low (~2%), but levels were greater for stocks from west and south Wales and southern England (8-12%). However, the latest estimates for south-west England (2003 to 2006), immediately prior to the closure of the fishery, indicated an exploitation rate in Ireland of only about 2% for the River Tamar stock (south-west England).

At the time of closure of the Irish coastal fishery it was calculated that up to 5,000 more 1SW salmon would return to English and Welsh home-waters each year, representing a 4% increase overall (based on levels at the time). Rivers in the south and west of England and Wales were expected to benefit the most.

Other homewater fisheries

Few tags of English and Welsh origin have been returned from homewater fisheries in Northern Ireland or Scotland. The exploitation rates of English and Welsh salmon in these fisheries have not been estimated, but are thought to be low.

Marine by-catch

The ICES North Atlantic Salmon Working Group has investigated concerns about the potential by-catch of salmon post-smolts and adults in pelagic trawl fisheries operating in the Norwegian Sea. Areas of overlap between the distribution of post-smolts and certain pelagic fisheries have been identified, but assessment of the level of by-catch has been constrained by insufficient knowledge about the temporal and spatial distribution of post-smolts and catches in pelagic fisheries. The Working Group has recognised that data derived from surveys conducted on commercial vessels using pelagic trawls will provide the most reliable indicators of by-catch, and previous assessments based on these data have indicated a fairly low level of impact. In 2005,

the Working Group estimated that the upper level of potential post-smolt by-catch (from a range of ~40,000 to 150,000 fish) was less than 5% of the estimated pre-fishery abundance (PFA) of salmon for the north-east Atlantic stock complex (ICES, 2005).

More recently, the pelagic fisheries in Nordic Seas and in the areas around Iceland have changed, raising new concerns about possible increased levels of salmon by-catch. The mackerel stock has expanded north-westwards during spawning and in the summer feeding migration, extending as far west as south-east Greenlandic waters. Significant catches of mackerel are currently taken in Icelandic and Faroese waters, areas where almost no such catches were reported prior to 2008. Catches from Greenland were also reported for the first time in 2011, and increased in 2012.

The latest by-catch estimates reported to the ICES Working Group arising from recent Icelandic and Faroese screening programmes suggest relatively low levels of by-catch in the mackerel catches (1 to 6 salmon per 1000 tonnes of mackerel and herring), consistent with earlier findings (ICES, 2014). However, markedly higher ratios of salmon to pelagic species (20 to 50 times more than those recorded in catch screening) were reported in salmon research surveys using pelagic trawls in Nordic Seas. It remains unclear how representative these data might be of the actual by-catch in the commercial fishery given differences in the design and operation of the gears used. However, even taken at face value, the capture rates remain quite low relative to the estimates of total north-east Atlantic PFA (<2%). It remains the case that assessment procedures based on direct screening of commercial catches are considered to provide the most reliable data for extrapolation purposes. It is, nonetheless, recognised that the catches in these pelagic fisheries have increased and substantial uncertainties remain as to the extent to which the migration routes of post-smolt and adult salmon might overlap in time and space with these pelagic fisheries.

The ICES Working Group previously concluded that there was insufficient information to allow any assessment of the effect of non-targeted fisheries on salmon abundance. This remains the case. The latest available data remain consistent with the view that salmon by-catches appear to have a relatively low impact on salmon PFA and returns to homewaters. However, the Working Group recognises that these estimates remain highly uncertain and considers it would be informative to increase efforts to obtain reliable estimates of the by-catch of salmon.

ASSESSMENT OF THE STATUS OF STOCKS

7. STOCK MONITORING

The Environment Agency and Natural Resources Wales monitor both stocks and fishery performance in most rivers supporting salmon stocks in England and Wales. This includes operating counters, undertaking surveys of juvenile fish and collecting fishery statistics. These data provide the basis for assessing the status of stocks and thereby determining the need for management actions. Further information on factors affecting stocks is collected to inform management decisions.

In addition to protecting the abundance of salmon stocks, managers need to maintain the diversity of stocks in terms of their biological characteristics. Measures of stock diversity potentially encompass a wide range of characteristics, but those of greatest significance for the management of stocks are the population structure within the river, the river age of the emigrating smolts and the run-timing and sea-age composition of the returning adult stock. There have been marked changes and trends in these characteristics among stocks around the North Atlantic over recent decades (e.g. ICES 2009, 2010; Russell *et al.*, 2012; Otero *et al.*, 2014), and in some cases these appear to be linked with variations in marine survival and trends in abundance. Monitoring changes in these characteristics therefore provides the potential to understand more about the factors affecting stocks and the potential to predict future trends.

The stock monitoring programme for salmon in England comprises several distinct elements:

- **Index rivers** – the Rivers Dee, Tamar, Lune and Tyne have been identified as salmon index rivers and provide monitoring sites for adults as well as the usual pattern of juvenile surveys. Data derived from these investigations aims to provide a better understanding of fishery dynamics and to facilitate and support processes, such as the setting of Net Limitation Orders (NLOs), Environmental Impact Assessments and the making of byelaws.
- **Temporal monitoring** – this programme provides long-term time-series of data for principal salmon fisheries (i.e. rivers with Salmon Action Plans); similar long-term monitoring also applies to other species. Sites in the temporal programme are surveyed biennially for salmon. Information from temporal monitoring sites can be used to show trends over a larger area, such as in a ‘State of the Environment’ report.
- **Spatial monitoring** – this programme is used to identify changes in the distribution of fish, to detect differences between groups of sites (for example, between habitat types or sub-catchments), to determine the distribution of species, and to provide a basic level of surveillance monitoring over the widest practical area. Sites in the spatial programme must be sampled at six yearly intervals; the spatial monitoring programme also utilises data from temporal sites.
- **WFD specific monitoring** – this occurs where coverage from other routine programmes does not provide all the data required for classification of sites. These sites are surveyed every six years.

- **Local investigative monitoring** – is designed to meet specific local needs. Local teams determine the site density and survey frequency for such monitoring by referring to best practice guidelines.

7.1 Surveys of salmon fry and parr

The juvenile salmon monitoring programme aims to: (1) identify trends in the juvenile population, and (2) provide an overview of the status of the population in a catchment and to identify those parts of the system that are under performing. Surveys are designed (number of sampling sites and periodicity) in order to provide predetermined levels of statistical significance (e.g. in detectable changes between years or sub-catchments). The inclusion of an assessment of habitat (HABSCORE) can further increase confidence in the detectable differences between spatial sites. The HABSCORE model (Milner *et al.*, 1998) is used to compare observed juvenile salmon abundance with numbers expected under pristine environmental conditions where recruitment is not limiting. Juvenile salmon surveys typically take place between June and September using electric fishing. Data derived from the surveys are routinely added to a data storage repository - the National Fish Population Database (NFPD).

The spatial monitoring programme requires that up to 12 sites per sub-catchment are sampled semi-quantitatively every 6 years, while the temporal programme comprises two sites per sub-catchment sampled semi-quantitatively every two years. This gives an approximate coverage of one spatial site per 5.3km and one temporal site per 42.4km of river length. In total, there are 919 spatial sites and 286 temporal sites in England that are salmon specific.

Juvenile salmonid monitoring in SW Wales
(photo courtesy of Paul Hyatt, Natural Resources Wales)

One output from the juvenile monitoring investigations is an assessment based on a classification scheme that produces a juvenile salmon density score for each site, using average values for the early 1990s as a baseline (Mainstone *et al.*, 1994). The scheme enables the proportion of sites falling into different salmon abundance classes (A to F) to be determined, and provides a measure of the health of the juvenile salmon populations for each river. Sites are typically grouped into those that are at or above average (Classes A to C), below average (Class D) and well below average or fishless (Classes E or F). This aggregated assessment for the most recent six-year period is provided in the annual assessment report.

Juvenile survey data are generally based on relatively small samples of the total population and must always be interpreted with care. Fish populations also vary considerably with time and location, and good time series are required to detect meaningful trends. Work is continuing to revise and update the procedures for collecting and interpreting juvenile data. For example, the Environment Agency has previously completed an R&D project to develop a “River Fish Habitat Inventory” (Wyatt, 2005). This methodology combines statistical modeling techniques with a Geographical Information System (GIS) for producing a quantitative inventory of the juvenile salmonid habitat and populations present within a catchment. The RFHI methodology has also influenced the development of a relatively new classification system (Fisheries Classification Scheme 2 - FCS2), which the Environment Agency has developed, in accordance with requirements set out in the European Water Framework Directive, to help prioritise actions to improve salmon stocks (and other fish species).

7.2 Smolt age and run timing

Many salmon stocks in England and Wales appear to have experienced a decline in mean smolt age over the past 30 years or more, largely based on the ageing of scales taken from returning adult fish. These changes are consistent with declines in smolt age in many other stocks around the North Atlantic (ICES 2009, 2010; Russell *et al.*, 2012). The decline in mean smolt age may have been the consequence of an increase in growth rate as the faster growing parr migrate to sea earlier. This, in turn, may relate to an increase in temperatures, and/or an increase in growth as a result of density-dependent processes, and/or increased freshwater production. However, while smolt age has apparently decreased over the longer term, more recent patterns in the mean smolt ages of salmon returning to the Rivers Tyne, Tamar, Dee and Lune suggest these are now increasing, from around 2003/2004 onward.

One possible consequence of an increase in growth rate and smolts migrating at an earlier age is to dampen the impact of an increase in marine mortality. This assumes that the higher survival rate to smolt for a one-year-old smolt (S1) is not outweighed by their higher marine mortality. However, a decline in smolt age may affect reproductive success as egg size is smaller for S1 as opposed to S2 smolts of the same sea-age and early survival (egg to swim-up) may also be lower (Moffett *et al.*, 2006).

In addition to changes in smolt age composition, it is apparent that smolt run timing is also changing, with a trend for fish to migrate to sea earlier over recent decades (Russell *et al.*, 2012; Otero *et al.*, 2014). The timing of smolt emigration has been linked to river temperature patterns, but has raised concerns about the subsequent survival of smolts when they reach the sea due to a possible increased thermal discrepancy between river water and the sea at the time of migration. Such a mechanism has been proposed for the River Bush in Northern Ireland, where the marine survival patterns in 1SW salmon have been strongly influenced by the run timing of the preceding smolt year, such that later emigrating cohorts demonstrated increased survival (Kennedy and Crozier, 2010).

7.3 Sea age and run timing

Run timing in adult Atlantic salmon is highly variable. Different sea-age classes of salmon have different patterns of run timing and these vary on a geographic scale, but also between stocks in a region and within stocks over time. A change in the pattern of run timing could therefore result from a change in the balance between the various sea-age classes, a change in run timing within sea-age classes or both. A more detailed review of run timing and sea age is provided by

ICES (2009, 2010). In the UK, 1SW salmon mainly enter rivers from June to August, though some rivers have strong autumn runs, 2SW fish enter throughout the year, but sometimes with spring, summer or later peaks, while 3SW fish generally enter rivers early in the year, with few entering after about May. Fish spawning for a second time tend to adopt similar run timing to that of their first migration.

Changes in the sea-age composition and run timing of salmon have been reported for numerous populations throughout their geographic range, including populations in England and Wales (e.g. Anon, 1994; Aprahamian *et al.*, 2008). Current information on the assessment of the sea-age composition in net and rod catches in England and Wales is provided in the latest assessment report.

An earlier analysis of long-term data sets for 12 salmon stocks in the UK (Anon, 1994), examined changes in the monthly pattern of catches and in the contribution of different sea-age classes. The spring component of the catches increased both numerically and as a proportion of total catch from 1910 to about 1930, remained generally stable until the early 1950s, but subsequently showed a steady decline to the low levels evident in more recent years. It was concluded that the dominant process in these shifts in timing of runs and catches was a change in sea-age composition. While there was some evidence of a shift in run timing within sea-age classes, this was evidently not the main mechanism of change.

For monitored rivers in England and Wales with longer time series dating back to the 1970s there is an apparent decrease in the proportion of 2SW (and older) salmon returning in the early part of the time series, with 1SW salmon predominating. More recently, however, this trend has reversed in some rivers and the proportion of 2SW and older salmon has been increasing.

7.4 Upstream counts of adult salmon

Electronic fish counters or traps are operated on a number of catchments to provide estimates of the upstream run of adult salmon and sea trout. Where it is possible to separate the species, the counts are adjusted to provide estimates of the numbers of returning salmon. Values for some counters have previously been adjusted retrospectively to accommodate new corrections or efficiency estimates. Time series of counts and returning stock estimates of returning adult salmon entering freshwater, including provisional estimates for the latest assessment year where available, are provided in the annual assessment report.

Forge Weir fish trap and counter on the River Lune (photo courtesy of the Environment Agency).

7.5 Tagging investigations

Tagging studies have often been employed to monitor stocks and to evaluate the outcome of different management initiatives. Various marks and tag types are used ranging from fin-clips, microtags and passive integrated transponder (PIT) tags, typically used in relatively large numbers on juveniles in population studies, to the use of radio and acoustic tags in behaviour studies.

Details of all the marked and tagged salmon released in England and Wales in the most recent calendar year are provided in the annual assessment report. These data are also collated and reported annually by ICES for all salmon producing countries in the North Atlantic.

7.6 Marine survival

There is extensive evidence from monitored rivers around the North Atlantic that the survival of salmon during the marine phase of their life-cycle has declined in recent decades, with a marked downturn around 1990. However, few data are available to evaluate long-term trends in marine survival for salmon stocks in England and Wales. Marine survival estimates over an extended period are reported in the annual assessment report for the River Corrib (Ireland), River Bush (Northern Ireland) and River North Esk (Scotland) (data from ICES, 2016). These data indicate that marine survival can be quite variable between stocks and between years, but has generally decreased since 1987. Shorter time series for the Rivers Dee (Wales), Tamar and Frome are also available in the annual assessment report and indicate similar low levels of marine survival in recent years.

7.7 Genetic sampling

There has been increasing focus in recent years on the use of genetic techniques to aid in the management of salmon stocks and fisheries. Work on establishing the genetic identity of salmon stocks in the principal rivers in England and Wales has continued, with the initial aim of providing a basis for identifying salmon to specific rivers or regions of origin. This has enabled patterns of exploitation in mixed stock fisheries to be assessed and has helped to inform management decisions. In time, such investigations may be able to answer a range of additional questions relating to the size and structure of breeding populations and the contribution of stocked fish. The work to date has complemented wider investigations to genetically characterise salmon stocks

elsewhere around the North East Atlantic, such as the SALSEA MERGE and Atlantic Salmon Arc Project (ASAP) programmes, and has used the same techniques and markers (micro-satellites) as in these other studies. Further details on the SALSEA MERGE investigations can be found at: http://www.nasco.int/sas/pdf/salsea_documents/salsea_merge_finalreports/Completed%20Final%20Report%20SALSEA-Merge.pdf.

One example of the use of genetic sampling in informing management is provided by work carried out on fish caught in the north-east coast fishery. An analysis of salmon caught in 2011 was used to help inform deliberations about the NLO renewal for the fishery. The analysis applied a genetic assignment approach using a baseline of genetic information in respect of populations of fish expected to contribute to the fishery – i.e. primarily rivers in north-east England and east Scotland. The ability to assign fish successfully depends on the baseline containing sufficient genetic variation to allow differentiation among the rivers/regions of interest. In practice, it was not possible to assign individual fish to their specific river of origin. However, it was possible to determine the proportions of the net catch that were from north-east English and Scottish rivers as regional groups. Genetic information was collected from a total of almost two thousand salmon from the fishery, with analyses performed on four different sectors: drift nets and 'T' nets in the Northumbria area, and drift nets and 'J' nets in the Yorkshire area. The estimated proportion of Scottish origin fish in the samples was: 70-75% in the Northumbrian drift nets, 30-50% in the Northumbrian 'T' nets, 60-70% in the Yorkshire drift nets and around 50% in the Yorkshire 'J' nets. This analysis was considered to provide a robust assessment of the relative contributions of different regions to the north-east English catch in 2011. It was noted, however, that it was not possible to be sure how levels may vary between years. More recently, similar genetic analyses have also been used to inform management deliberations in relation to the net and fixed engine fishery in the Severn Estuary.

Genetic analysis work is ongoing to determine the levels of resolution and associated assignment probabilities that can be obtained using Single Nucleotide Polymorphic (SNP) genetic markers. Samples of salmon from north-east English rivers are being screened and together with information from Scottish rivers, the resolving power between different rivers and assignment success rates to each river will be determined. A final report is expected in 2016.

A study has also been completed on the population structure of the Rivers Dove and Churnet (Trent catchment) using microsatellite analysis. It suggested that the extensive introductions to these rivers from stocked fish, whose parents originated from elsewhere, had contributed to a lack of genetic structuring, probably exacerbated by a limited starting gene pool (Environment Agency, 2014b).

A further investigation has explored the genetic origin of the salmon recolonising the River Mersey (Ikediashi *et al.*, 2012). Following extensive restoration work on the river from the 1970s, salmon were first observed back in the Mersey in 1999. Subsequently, a fish trap was installed and additional adults are now routinely sampled. In this study, 138 adults and one juvenile salmon sampled over the period 2001–2011 were genotyped at 14 microsatellite loci. Assignment analysis was carried out using a recently compiled pan-European microsatellite baseline to identify their most probable region of origin. This indicated that fish entering the Mersey originated from multiple sources, with the greatest proportion (45–60%, dependent on methodology) assigning to rivers in the geographical region just north of the Mersey, which includes north-west England and the Solway Firth suggesting fish were mainly straying in a southerly direction. Fish from other regions were also recorded. However, the number of fish originating from proximal rivers to the west of the Mersey was lower than expected.

8. ASSESSMENT OF STOCK STATUS

The status of individual river stocks in England and Wales is evaluated annually against stock conservation limits (CLs) and management targets (MTs) in line with the requirements of ICES and NASCO. A national assessment of the status of the salmon resource in England and Wales is also undertaken annually, using the Pre-fishery Abundance (PFA) and National Conservation Limit Models (Potter *et al.*, 2004), and reported to ICES to assist with the development of management advice for the distant water fisheries.

8.1 Assessment procedure for river stocks

In England and Wales, CLs have been developed that indicate the minimum spawning stock levels below which stocks should not be allowed to fall. Details of the process for setting CLs and assessing compliance with these biological reference points are given in Annex 7. The CL for each river is set at a stock size (defined in terms of eggs deposited) below which further reductions in spawner numbers are likely to result in significant reductions in the number of juvenile fish produced in the next generation. In reviewing management options and regulations, the Environment Agency and Natural Resources Wales also use an over-arching management objective that a river's stock should be meeting or exceeding its CL in at least four years out of five (i.e. >80% of the time) on average. A management target (MT) is set for each river, representing a spawning stock level for managers to aim at in order to meet this objective. Details of all the CLs and MTs for the 64 principal salmon rivers in England and Wales are provided in the annual assessment report.

The CLs for individual rivers typically remain fixed from year to year. However, these can be revised in light of new data or where changes occur to the catchment. For example, the CL for the River Wye in Wales has been revised in recent years as a result of efforts to open up previously inaccessible parts of the catchment to adult salmon. A new fish pass was installed on the River Monnow, a Wye tributary, in autumn 2008 and a further impassable barrier was removed on the Monnow in 2011. Together, these improvements have opened up almost 175 km of newly accessible habitat. A counter located in the fish pass has been used to monitor the natural recovery (no supplementary stocking has taken place or is planned) in the tributary. The accessible wetted area and CL for the Wye have both been revised; the CL was increased from 35.7 million eggs to 38.6 million eggs.

Annual compliance with the CL is assessed using egg deposition estimates. These are derived from returning stock estimates, where such data are available, but for rivers without traps or counters, the usual procedure for estimating egg deposition involves derivation of run size from rod catch using estimates of exploitation (and an appropriate adjustment for under reporting). Currently, these procedures do not take into account annual changes in fishing effort. In years when effort was low - such as the 'low-flow' year of 2003 and the 'foot-and-mouth' disease year of 2001 - this approach has probably resulted in rod exploitation being over-estimated on a number of rivers and hence escapement and egg deposition being under-estimated. In wetter years, when conditions are more favourable for angling, and fishing effort increases, the opposite is likely to be true. Ideally, an improved procedure is needed to take account of annual changes in fishing effort, as well as partitioning effort between salmon and sea trout (no distinction is currently made between these species when reporting fishing effort (but see analysis in Section 3.4). Many rivers, and particularly some of the smaller catchments on the west coast of Wales, support relatively small salmon stocks and are principally regarded as sea trout rivers. Current procedures may also fail to take adequate account of this.

8.2 Status of river stocks in the latest assessment year

Egg deposition estimates are calculated annually for each of the 64 main salmon rivers in England and Wales and a 10-year time series for each river, expressed as the proportion of the CL attained and including provisional data for the latest assessment year, is provided in the annual assessment report. A summary of these data, indicating the number of rivers with egg deposition estimates above their CL, between 50% and 100% of their CL, and below 50% of their CL for all years since 1993 is also presented. This table is adjusted annually to take account of the routine correction of the previous year's estimates, but also where some time series of egg deposition estimates have been revised in light of new information.

8.3 Compliance with the management objective

The 'management objective' for salmon stocks in England and Wales is that they should meet or exceed their CLs in at least four years out of five, on average. Compliance with this objective is calculated annually for all 64 principal river stocks in England and Wales for the latest assessment year and forecast for five years ahead. The compliance details for the latest assessment year and a time series of compliance assessments for the rivers in both England and Wales are provided in the annual assessment report. Full details of the compliance assessment process are provided in Annex 7.

8.4 Assessment of pre-fishery abundance (PFA) for England and Wales

Each year, the ICES North Atlantic Salmon Working Group makes an assessment of the status of the salmon stocks in the North East Atlantic (NEAC) area as a basis for advising managers and providing catch advice for the distant water fisheries. A key part of this assessment is the estimation of the pre-fishery abundance (PFA) of all NEAC stocks (full details of the assessment process are provided in Annex 5). The PFA of salmon from countries in the NASCO-NEAC area is defined as the number of fish alive in the sea on January 1 in their first sea-winter. This is split between maturing (potential 1SW) and non-maturing (potential MSW) fish. ICES uses estimates of PFA for the period 1971 to the present to investigate the effect of fisheries and other natural and anthropogenic factors on stocks. ICES also uses these estimates to develop a forecast of PFA for coming seasons in order to advise on management actions for the distant water fisheries.

Whilst the model is acknowledged as containing a number of uncertainties, it endeavours to provide our best interpretation of what the available catch and effort data may tell us about changes in the status of the total national stock of salmon over the past four to five decades. It is important to note that the overall national trends estimated by the model will mask conflicting changes in individual river stocks. Many river stocks in England and Wales have declined substantially in the past 30 to 40 years, but these will tend to be obscured by the very substantial improvements and recovery in others, such as the Tyne and Wear. The model sums all of these trends. Furthermore, the model is likely to provide a more reliable picture of the medium-term trends than of the year-to-year fluctuations.

The latest estimates of the PFA of salmon from England and Wales are provided in the annual assessment report. This has declined by approaching 50% from the early 1970s to the present time. Over much of the period, the decrease has tended to be somewhat greater for the non-maturing (i.e. potential MSW) component of the PFA than the maturing 1SW (i.e. potential grilse) component. However, there has been a marked reduction in the PFA of 1SW salmon in the last five years, and this difference is now less apparent. The results also suggest that there

was a marked decline in PFA around 1990, which is consistent with the general perception of a decrease in the marine survival for many stocks around the North Atlantic at about this time. It should be noted that the model cannot provide an estimate of PFA of potential MSW fish for the most recent year, because this requires information on the returns of these fish to homewaters, which won't occur until the following year.

The latest estimates of the numbers of salmon returning to rivers in England and Wales (prior to exploitation in homewater fisheries) and spawning are also available in the annual assessment report. The number of returning fish shows a similar downward trend to the PFA, although the decrease is less marked due to the reduction in net fishing exploitation in distant water fisheries. Thus, numbers of returning fish are estimated to have declined by about 45% between the early 1970s and the present time. As with the PFA, the decline in returning MSW fish has tended to be greater than that of the 1SW (grilse) returns over much of the time period, although a higher proportion of MSW fish has been observed in recent years. The difference between the estimated numbers of returning fish and those surviving to spawn has reduced progressively over the time series and the total spawning escapement has remained reasonably consistent over the time period. This reflects the marked reduction in homewater net and rod fisheries, including the increasing use of C&R. The recent upturn in MSW returns means that MSW spawner numbers are now similar to those at the start of the time period. This will be expected to have a disproportionate effect on egg deposition, given the substantially higher fecundity of these larger fish.

STOCK CONSERVATION AND MANAGEMENT CONSIDERATIONS

9. OTHER FACTORS AFFECTING STOCKS, FISHERIES AND CATCHES

9.1 *Condition of returning adult fish*

In recent years, concerns have been expressed not only about higher levels of salmon mortality at sea, but also about the size and condition of returning adult fish. For example, Todd *et al.* (2008) have reported unusually small returning 1SW fish in some Scottish rivers and have linked this to indirect effects of warming in areas where salmon are located at sea. The results were considered consistent with other analyses in providing evidence of major, recent climate-driven changes in north-east Atlantic pelagic ecosystems, and the likely importance of bottom-up control mechanisms resulting in changes in the quality and/or quantity of available prey. While this study drew no connection with stock abundances, it also showed that under-weight individuals had disproportionately low reserves of stored lipids, which are crucial for successful spawning.

Information on the condition of returning adult fish in England and Wales is collected on a small number of monitored rivers. Data for recent years indicate a strong correlation in the condition of 1SW and 2SW salmon sampled in head-of-tide traps on the Rivers Tamar and Dee - suggesting common marine factors are influencing the growth of fish returning to these two west coast rivers. For the River Dee, where a longer run of data (starting in 1991) is available, the mean condition of both sea age groups declined sharply in the late 1990s but has shown signs of stabilisation (1SW salmon) or recovery (2SW salmon) in recent years.

While variations in the size (weight) of returning salmon are factored-in to procedures for estimating egg deposition and compliance with CLs on all rivers, decline in condition – which may have implications for survival of fish as well as fecundity – remains a concern.

9.2 *The effect of river flows on angler effort and catches*

For rod fisheries, river flow is a key factor affecting both availability of fish and angler effort. The ability of salmon to enter river systems from the sea and successfully migrate upstream to spawning areas is strongly influenced by the prevailing flow conditions. Extended dry periods can delay or prevent upstream movements resulting in smaller numbers of fish available to anglers. When such conditions occur in the summer, water temperatures can also become elevated with potential adverse effects for fish. In wetter periods, migration is likely to be facilitated, making fish more readily available, although angling activity is restricted during periods of high flow, with fishing conditions commonly considered to be optimum as a river falls away and clears after a spate.

The timing and pattern of rainfall events over a year can thus have a marked influence on the migratory behaviour and run timing of returning fish and on their availability to anglers within the fishing season. This, in turn, has a direct impact on angler effort, with this typically being focused on periods considered to provide the most suitable fishing conditions. Given that many climate change models for the UK predict drier summers and wetter winters in the future, river flow conditions may play an increasingly important part in influencing salmon runs and catches.

A summary of the mean monthly flows for 12 rivers across England and Wales for the most recent year, assessed against long-term trends, is provided in the latest annual assessment report, together with a similar assessment of monthly rod catches for the majority of these rivers also expressed in relation to long-term trends.

9.3 Extreme flow events

Concerns have been raised about the effects of extreme flows on local salmon stocks in England and Wales. Extreme floods may affect both juveniles (e.g. through wash-out of redds and/or fry/parr) and returning adult fish (e.g. by reducing their ability to migrate upstream and spawn successfully). Low flows can also affect adult migrations and spawning, and juveniles, for example, through loss of habitat and increased vulnerability to predation (Riley *et al.*, 2009). Particularly severe floods occurred towards the end of 2015 in a number of regions in England and Wales, and coincided with the spawning period. It is currently unclear what effect this may have had on spawning success or fry and parr densities.

However, some flow impacts have not been as serious as first feared. For example, the River Derwent in North West England experienced an extreme (1 in 1,000 year) flood event in November 2009 with reports of extensive damage to river habitat. However, subsequent electric fishing surveys indicated that there was no significant impact on fry or parr numbers in the river, and anecdotal evidence suggested that the smolt run in 2010 was relatively strong. The floods are reported to have had some effect on the topography of the river, with an impression that some pools improved for fishing following the floods, while others deteriorated.

9.4 Water and habitat quality

A wide range of natural and man-made factors have the potential to influence Atlantic salmon during the freshwater stages of their life-cycle, and these need to be investigated and monitored to help direct and prioritise management actions. Earlier reviews of stock status have identified that key pressures on salmon fisheries in England and Wales include deficiencies in land management, degradation of in-river salmon habitat and effects of diffuse pollution and siltation. These reviews further highlighted that concerted and integrated action is required at a broad scale to address these issues.

Although salmon have been returning strongly to some historically polluted rivers (e.g. Tyne and Wear), there is concern about chronic environmental degradation in others, mainly in rural areas, caused by changing land-use practices, especially agriculture and forestry. Issues of particular concern are siltation resulting from soil erosion (Collins *et al.*, 2013), diffuse pollution such as pesticides from sheep-dip chemicals (Moore and Waring, 1995, 2000), herbicides (Moore and Waring, 1998; Moore *et al.*, 2007), run-off from industrial processes (Lower and Moore, 2007) and effluents from fish farms (Waring *et al.*, 2012), and also acidification and water abstraction. The relative importance of these effects vary around the country, but clusters of high pesticide levels have been found in Welsh upland streams, and acidification still occurs in the uplands of Wales and north-west England. The nature and extent of soil erosion impacts have also previously been investigated. Salmon runs in the chalk-streams of southern and south-west England have declined since the 1980s, but the reasons for this are not clear though, increasingly, concerns are being expressed regarding the impact of climatic changes (Solomon and Lightfoot, 2009) and low flows (Riley *et al.*, 2009). It is also increasingly evident that water quality issues in freshwater may have a significant impact on the survival of salmon when they enter the marine environment (Waring and Moore, 2004).

Factors affecting individual river stocks are identified and prioritised in plans for catchments supporting the 11 River Basin Management Plans for England and Wales. Priority for action is given to improving those water bodies that are not achieving 'Good Ecological Status' and/or fisheries that are below CLs and to those actions likely to generate the most gain (see Sections 11.1-11.2 for more information).

A new adaptive system for managing water resources in the face of climate change, water demand and changing environmental standards is being developed in line with provisions under the Water Act, 2014. This aims to rationalise and simplify the abstraction licensing system, facilitate the more efficient use of water resources through licence trading and provide for more sophisticated environmental standards. Implementation is expected in the early 2020s. New abstraction authorisations are also to be implemented between 2016 and 2018. This will bring currently unlicensed activities such as trickle irrigation, de-watering in quarries, Canal and Rivers Trust water transfers and Inland Drainage Board abstractions into regulation.

9.5 First sale price of salmon

The price of salmon sold for food is a key factor determining the value of the catch of salmon caught by net fisheries with potential implications for fishing effort and the economic viability of those fisheries and this, in turn, has been affected by the rapid expansion in the production of farmed salmon over the past three decades. In recent years, wild salmon have comprised less than one per cent of the boxes of salmon sold at Billingsgate fish market; the remainder being farmed salmon, predominantly from Scotland.

The average monthly price of fresh, wild salmon sold at Billingsgate varies seasonally, reflecting both availability and the size of fish. Wild grilse (1SW salmon) are most abundant in the later months and have a smaller average size, hence the lowest price occurs in August and September. Fresh salmon caught in English and Welsh waters are only available during the open season for nets and fixed engines so are not on sale before June or after August.

Long-term trends in average salmon prices are presented in the annual assessment report for one month, August, to avoid seasonal variation; the prices have been adjusted by the Retail Prices Index (Mawle, in prep). The price of wild salmon declined from the late 1970s, when farmed salmon first came on the market, to 1995. This is despite a falling catch of wild salmon and coincides with the increased production of farmed salmon in the UK. Over this period, the price of farmed salmon was a good predictor for the price of wild salmon, since although wild salmon maintained a premium, the price of wild and farmed salmon shared a common trend. However, since 1997, the prices of wild and farmed salmon have diverged, with wild fish commanding a much higher price than that of farmed fish, for which the average August price has remained relatively consistent. The changes suggest that wild salmon have recently commanded a separate market, unrelated to the price of farmed salmon.

10. EXISTING AND EMERGING THREATS TO SALMON POPULATIONS

10.1 Climate change

Changes in climate are global, and the increased natural mortality of salmon at sea in recent years may be linked to climate change (Chaput, 2012). There is also growing interest in the role that global climate change might play in modifying the freshwater environment (Russell *et al.*, 2012;

Otero *et al.*, 2014). The higher temperatures predicted as a result of climate change are predicted to affect all components of the global freshwater system (IPCC, 2007). Scenarios for future climate change (Hulme *et al.*, 2002; Jenkins *et al.*, 2009), suggest that warming trends are likely to be far more severe in the coming decades than those experienced in the past – even under the best case ‘low emissions’ scenario. Changes in the British climate are predicted to become more pronounced (Hulme *et al.*, 2002) and the most likely scenarios are for higher temperatures, wetter winters, drier summers and more extreme events of flooding and drought.

- Jonsson and Jonsson (2009) provide a comprehensive review of the potential effects of climate change on the different life-stages of Atlantic salmon, with particular reference to water temperature and flow. These effects include: increased growth of parr and reduced smolt age; earlier smolt migrations with possible increased early post-smolt mortality due to greater increases in river temperatures compared with marine habitats; earlier spawning migrations under suitable flow conditions, but delays and increased levels of straying under extreme flow conditions; and decreased post-smolt growth, survival, age at sexual maturity and recruitment, particularly in the southern parts of the distribution range. They also suggest a northward shift in the thermal niche of the species, with decreased production and population extinction in the southern part of the distribution and expansion in the north.

10.2 Red Vent Syndrome

The occurrence of salmon returning to rivers in England and Wales with swollen and/or bleeding vents has been noted since 2004. The condition, referred to as Red Vent Syndrome (RVS), has continued to be observed since this time.

Monitoring programmes on salmon ‘index’ rivers provide the most consistent measure of the incidence of RVS. Since 2007, this consistency has been improved through the introduction of a system whereby symptoms have been classified according to their apparent severity (with samplers referring to a set of standard photographs and descriptions to assist their judgement). Time series of RVS incidence in returning fish are available in the annual assessment report for the Rivers Tyne, Tamar, Dee, Lune and Caldew (a tributary of the River Eden), extending back to 2004 in the case of the Dee.

The trapping records indicate that RVS has generally been less prevalent in early and late running fish than mid-season fish. Early running fish comprise mainly MSW salmon whereas late running fish are predominantly 1SW fish. Monitoring on the Caldew has previously indicated a higher incidence of RVS in female than male fish; and provisional results from the Dee suggest no significant differences in the condition factors of affected and unaffected fish.

Preliminary investigations on both the Tyne and the Dee have indicated that salmon with affected vents often show signs of healing during the period of in-river residence. It appears from these initial findings that the time when a fish is examined for RVS relative to its period of in-river residence is likely to influence perceptions about the prevalence of the condition. Thus, the relatively low incidence of RVS in fish sampled on the Tyne and the Caldew may reflect the longer in-river residence of fish sampled at these sites compared to the other (lower river) sampling locations. This is further supported by evidence from the Tyne in 2011 when a sample of fish taken in the estuary and lower river showed a far higher incidence of RVS (~12%) compared to upper river broodstock samples (~4%), the latter being the usual sampling location.

The cause of RVS has been linked to the presence of a nematode worm, *Anisakis simplex* (Beck *et al.*, 2008). This is a common parasite of marine fish and is also found in migratory species. However, the larval nematodes are usually found spirally coiled on the mesenteries, internal organs, and less frequently in the somatic muscle of fish, and it is unusual for them to be located in the muscle and connective tissue surrounding the vent. The reason for the occurrence of the nematodes in the vents of migrating wild salmon, and whether this might be linked to possible environmental factors, is unclear. The potential significance of the swollen vents, or whether the severity of the vent damage could impair spawning, is also unclear. However, the healing of vents described above, and reports of the successful stripping of affected hatchery broodstock and the normal development of their offspring, suggests the effects of the condition - at least on spawning success - may be small.

A press release was issued in 2007 to advise anglers in England and Wales about RVS and to provide reassurance that there are no risks to human health if fish are processed and cooked properly.

10.3 Other disease issues

The Environment Agency and Natural Resources Wales also maintain a watching brief regarding other possible disease issues on all major salmon rivers. For example, in some recent years, a number of reports have been received of Atlantic salmon and sea trout showing signs of fungal infections. In 2015, in response to reports of fungal infections affecting salmon (and sea trout) across England and Wales, and in particular in the River Dart and Yorkshire Esk, advice was provided and sampling/monitoring undertaken by the Environment Agency and Natural Resources Wales in collaboration with fisheries interests. On the River Dart, an emergency byelaw was implemented in mid-July, requiring the seine net fishery to release all salmon and close early and rod anglers to practice 100% C&R; spinning was also banned to reduce stress on released fish and support the river's spawning escapement.

There have also been some recent reports from anglers of fish showing symptoms believed to be consistent with the disease Ulcerative Dermal Necrosis (UDN) (Chris Williams pers com). However, while laboratory examinations revealed lesions perceived to be consistent with early UDN from one fish, detailed examinations proved these were not typical of the disease. No recent cases of UDN have, therefore, been confirmed from England and Wales.

10.4 Renewable energy schemes

Many of the hydropower installations in England and Wales have focused on run of river schemes that are typically associated with in-river structures such as weirs or old mills and rely on making use of differences in the levels of water (head). Such structures may already be impacting upon the ability of salmon to migrate upstream and downstream. Where such structures are no longer required efforts are often made to remove them to improve connectivity within catchments, but where the structures must stay, fish passes will need to be employed to allow fish passage to take place. The position of fish passes in relation to the location of a hydropower scheme is critically important to the effectiveness of the pass.

Where run of river schemes make use of existing mill leats, the distribution of flow between the leat, river, by-wash and fish pass is also important. Poorly designed schemes could result in either the inability of fish to migrate or delays to migration. These delays could also lead to enhanced predation or a reduced distribution of adult fish during the spawning period.

Most hydropower turbines need to incorporate screens at both their intake and outfall to safeguard fish moving both downstream and upstream. The aperture of these screens depends on the size of fish requiring protection and the potential impact on fish if they were to pass through the turbine.

The Environment Agency controls the potential for impact from these various sources by requiring developers in England to follow its 'Guidance for run-of-river hydropower development', which is available on request from the Environment Agency. This guidance describes the measures that need to be adopted to ensure appropriate environmental protection. Similar provisions apply in Wales and guidance is available at:

<https://naturalresources.wales/apply-for-a-permit/water-abstraction-licences-and-impoundment-licences/hydropower/before-you-apply/?lang=en>.

In looking to meet the targets for renewable energy production, efforts are also increasing to promote and develop offshore renewables. Such developments also have the potential to affect fish stocks through factors such as increased underwater noise (e.g. from piling), sediment plumes and electro-magnetic fields. The likelihood of any impacts on Atlantic salmon will depend on interactions between the migratory routes and behaviour of the fish, the location and extent of offshore developments, the technologies used and the status of the particular stocks in an area. The available information on the migration and behaviour of salmon at sea is limited. Nonetheless, it will be important to ensure that potential environmental impacts are assessed and, if necessary, minimised through appropriate mitigation to ensure that new marine energy industries develop on a sustainable basis.

11. SALMON CONSERVATION ACTIVITIES AND OPPORTUNITIES FOR SALMON MANAGEMENT

11.1 Environmental improvements delivered through River Basin Management Plans

Improving the environment is key to improving salmon stocks and hence catches. In parallel with exploitation control measures, concerted and integrated action is being taken to address the environmental problems limiting salmon production in many catchments in England and Wales.

The European Water Framework Directive established an integrated approach to the protection, improvement and sustainable use of rivers, lakes, estuaries, coastal waters and ground-waters. Salmon management in England and Wales is becoming increasingly linked with this Directive and its 6-year planning cycle. The Directive requires the drawing up of River Basin Management Plans (RBMP) and Programmes of Measures (PoM) with the aim of achieving Good Ecological Status or, for artificial or more modified waters, Good Ecological Potential.

England and Wales has been divided into eleven River Basin Districts (RBDs) including the cross-border Solway and Tweed RBD which is partly in Scotland. The RBDs have been 'characterised' by assessing the pressures and impacts on the water environment, such as overuse or pollution. A RBMP for each District was published in December 2009 setting out how these impacts will be reduced through its Programme of Measures (PoMs). Much more information about the Directive, its RBMPs, the catchment scale approach that is being taken and the programme of associated investigations can be found on the Gov.UK website [here](http://www.gov.uk/government/uploads/system/uploads/attachment_data/file/164442/rbmds.pdf) and the Rivers Trust's website at: <http://www.riverstrust.org/environment/wfd/index.htm>.

As part of this process, assessment procedures have been developed to identify those rivers where fish populations are at less than good status and the reasons why. The main pressures affecting salmon have been identified as issues around channel morphology (including barriers to fish migration), sediment and hydrology (including abstraction and flow modification). Monitoring programmes chart progress towards achievement of Good Ecological Status or Potential. The second round plans were published in 2015.

In the latter stages of implementing the first round plans, use of the Government's Catchment Restoration Fund through partnerships involving the Environment Agency, Natural England, Natural Resources Wales, Wildlife Trusts, Rivers Trusts and others delivered many river improvements that should benefit salmon.

Examples of environmental improvements are also reported in the annual progress report to NASCO detailing actions against the current Implementation Plan; the latest such report is available at: http://www.nasco.int/implementation_plans_cycle2.html.

11.2 Improving riparian shade to help combat climate change effects

'Keeping Rivers Cool' is a four year (2012-2016) Environment Agency-led climate change adaptation project focused on using riparian shade to keep rivers cool. The UKCP09 Climate Projections (Jenkins *et al.*, 2008, 2009) predict a rise in average air temperature of 2-4°C by 2050. There is already evidence of warming from the Environment Agency water temperature archive and temperatures of >31°C have already been recorded in small streams in southern England (Broadmeadow *et al.*, 2011). Studies have shown that shaded river channels can be 1.5°C lower on average than open reaches or 2-3°C in maximum temperatures (Bowler *et al.*, 2012); larger stretches associated with woodland can be up to 5°C cooler.

The 'Keeping Rivers Cool' Project aims to benefit salmon and trout by reducing river temperatures throughout upland England and Wales. It works by inspiring action through demonstration projects, guidance and mapping tools.

Mapping tools and guidance have been developed to identify where riparian shade is lacking and where to target resources and the latter has been distributed to landowners and partners. A copy can be downloaded at:

<http://www.ecrr.org/Publications/tabid/2624/mod/11083/articleType/ArticleView/articleId/3370/Keeping-Rivers-Cool.aspx>. Pilot projects have been set up on the Rivers Tyne, Hampshire Avon, Wye and Ribble.

11.3 Stocking and hatchery-origin fish

Juvenile salmon (eggs, fry, parr and smolts) have previously been stocked from hatcheries in a number of catchments by the Environment Agency, Natural Resources Wales and private fishery interests, and some such stocking activities continue. Stocking purposes include mitigation, restoration, enhancement (private schemes only), investigation, and legal obligation. Full details of the numbers of fish stocked in these programmes, and the stage (eggs, fry, parr and smolts) of release, are included on a catchment by catchment basis in the annual 'Salmonid and Freshwater Fisheries Statistics' publications, which are available at:

<https://www.gov.uk/government/collections/salmonid-and-freshwater-fisheries-statistics>.

All keeping and introduction of fish in inland waters is subject to permitting by the Environment Agency in England and Natural Resources Wales. The Environment Agency has a national approach to stocking together with specific guidance on 'Schemes to stock rivers with salmon, sea trout and brown trout from locally sourced broodstock', which outlines the risks and difficulties of such programmes. From 2013, salmon management in Wales fell under the remit of a new body - Natural Resources Wales (NRW). Following a review of the scientific evidence and a public consultation exercise, NRW announced in October 2014 that it would be stopping future stocking of Atlantic salmon and sea trout into Welsh rivers.

There has been no formal requirement for juvenile fish stocked into rivers in England and Wales to be marked. Thus, if stocked juveniles return as adults, they cannot usually be distinguished from fish derived from natural spawning, although scale analysis may enable this. Marking and tagging programmes are undertaken in some areas to assess the impact of stocking programmes (Section 7.3), but few results are available from these initiatives.

An examination of mitigation stocking on the River Tyne (Milner *et al.*, 2004) reviewed the role that a stocking programme played in the recovery of the Tyne fishery. In the 1950s, salmon runs in the River Tyne were severely depleted due to estuarine pollution. However, the river now consistently produces the largest rod catch in England and Wales. Water quality improved between the 1960s and 1990s, following reduction in industrial activity and improvements to effluent treatment and disposal. This coincided with a salmon stocking programme, which started in 1979 as mitigation for lost production resulting from the construction of a new reservoir (Kielder Reservoir). An extensive review of the observed patterns of change in rod catches, juvenile abundance, estuarine water quality and returns of stocked fish marked with coded wire microtags indicated that natural recovery was the dominant process. However, the contribution of stocked fish, which peaked in 1986, is believed to have accelerated and stabilised stock recovery in its early stages when water quality improvements were still inconsistent.

The River Thames provides another example of a restoration programme based on stocking. Attempts to restore salmon to the Thames showed initial promise in the 1980s and 1990s with up to 300 adults returning each year. However, after 2000 the programme saw declining returns, with typically less than 20 fish returning annually. The stocking programme has now ceased. The decline coincided with increased likelihood of unfavourable flow and water quality conditions in the tidal river. Earlier investigations (Alabaster and Gough, 1986) indicated that a freshwater discharge in excess of 650 megalitres per day (MLD) was needed at the tidal limit to enable salmon to pass through the Thames tideway. Summer flows have been below this level in a number of years and intermittent storm events have also resulted in significant discharges of raw sewage and rainwater from combined sewage overflows with resultant impacts on water quality. River temperatures in the summer months have also increased in recent years and may be affecting migration into freshwater. A genetic analysis (Griffiths *et al.*, 2011) indicated that many of the salmon entering the Thames in recent years predominantly originated from other rivers in southern England, highlighting the potential for natural processes of re-colonisation to operate in rivers where salmon have become locally extirpated.

Analysis of angler catch statistics from 62 rivers in England and Wales suggest stocking programmes have had little effect on total rod catch or catch per unit effort between 1995 and 2009 (Young, 2013). The relatively small scale of stocking and low survival of stocked fish (Harris, 1994) is consistent with the finding that stocking programmes have little effect on adult abundance in England and Wales. It remains unclear to what degree the absence of detectable demographic effects result from the small scale of most programmes, the low survival of stocked fish, or

stocked fish compensating for stocking induced declines in natural recruitment (e.g. Chilcote *et al.*, 2011). There is, however, increasing evidence that stocking can pose a threat to wild salmon populations.

Efforts to further develop a consensus on the issue of salmon stocking were advanced at a salmon stocking conference held in Glasgow in November 2013 hosted by the Atlantic Salmon Trust and IBIS. This was attended by a large numbers of scientists, managers and stakeholders, and resulted in some short guidance documents, including a paper summarising the current scientific consensus on salmon stocking (as viewed by the majority of those attending). Details are available at: <http://ibis-eu-know.weebly.com/nov-2013--salmon-stocking-glasgow.html>

ANNEX 2. Glossary of terms and abbreviations used in this report

This glossary has been extracted from various sources, but chiefly the EU SALMODEL report (Crozier *et al.*, 2003) and Environment Agency reports.

Adult Salmon after the middle of the first winter spent at sea, after which the main categorisation is by sea-age, measured in sea-winters (e.g. grilse, or 1SW; two sea winter, or 2SW).

Abstraction Taking water, either permanently or temporarily, from a water source (river, stream, spring, pond, lake or groundwater).

Anadromous fish Fish, born in freshwater, that migrates to sea, to grow and mature, and then returns to freshwater as an adult to spawn (e.g. salmon, sea trout).

Buy out Payment made to a net fisherman to permanently relinquish his/her fishing licence.

Buy off Payment made to a net fisherman to cease fishing (for all or part of the fishing season) on a temporary basis. The fisherman retains entitlement to a licence, and a licence is issued to him/her each season.

By-catch The capture of non-targeted fish.

Catchment The area of land drained by a river (e.g. River Tyne catchment).

Conservation Limit (CL) The minimum spawning stock levels below which stocks should not be allowed to fall. The CL for each river is set at a stock size (defined in terms of eggs deposited) below which further reductions in spawner numbers are likely to result in significant reductions in the number of juvenile fish produced in the next generation.

Dissolved oxygen The amount of oxygen dissolved in water; one of the features that is used to classify water quality.

Distant-water fisheries Fisheries in areas outside the jurisdiction of the country of origin of the exploited stock. With respect to the NASCO convention, this specifically refers to the fisheries under the jurisdiction of the Faroe Islands and Greenland.

EU Directive A European Union legal instruction, binding on Member States, but which must be implemented through national legislation within a prescribed time-scale.

Escapement Fish that survive to spawn after exploitation of the stock.

Exploitation Removal of fish from a stock by fishing.

Extant exploitation rate Catch of fish from a particular stock divided by the number of fish from that stock estimated to be alive at the time of the fishery.

Favourable condition A term used in relation to the EU Habitats Directive (92/43/EEC) where a designated feature and its associated environment is in good ecological condition.

Favourable conservation status A term used in relation to the EU Habitats Directive (92/43/EEC) where a habitat or species is in a state where its distribution, abundance, structure or function is sustained throughout the biogeographic region over the long term.

Focus Area Reports (FARs) Reports prepared by each relevant jurisdiction within NASCO providing an in-depth assessment of measures being taken or planned to implement NASCO Agreements, Resolutions, and Guidelines in relation to Fishery Management, Protection, Restoration and Enhancement of Salmon Habitat, and Aquaculture and associated activities.

Fishery The area where it is, or may be, lawful to fish and where the resource is exploitable.

Fixed engine (FE) The term fixed engine is an ancient one used in the UK as a general descriptor of stationary fishing gears.

Fry Young salmon that have hatched out in the current year, normally in May at the stage from independence of the yolk sac as the primary source of nutrition up to dispersal from spawning areas (redds).

Good ecological status A key target under the EU Water Framework Directive. Water bodies of 'good ecological status' should have the biological and chemical characteristics expected under sustainable conditions. Practicality and the cost to society have to be considered in achieving this and this principle is also inherent in the WFD.

Good ecological potential An alternative key target under the EU Water Framework Directive. Water bodies that have been artificial or physically altered to fulfil important uses such as flood and coastal risk management are designated as Heavily Modified Waterbodies (HMWBs) under WFD. These water bodies are set the alternative target of Good Ecological Potential (GEP), which is the maximum ecological quality they could achieve given the constraints imposed upon them.

Grilse An adult salmon that has spent only one winter feeding at sea (1SW salmon) before returning to freshwater to spawn; normally only applied to salmon in homewaters.

Homewater fisheries Fisheries within the jurisdiction of the countries of origin of the exploited stocks (within 12 miles of the shore).

IBIS (Integrated Aquatic Resources Management between Ireland, Northern Ireland and Scotland) A partnership between the Loughs Agency, Queen's University Belfast, and the University of Glasgow, supported by the EU's INTERREG IVA Programme.

Implementation Plan Reports prepared by each relevant jurisdiction within NASCO describing proposed approaches for meeting the objectives of NASCO's Agreements, Resolutions, and Guidelines.

Management target (MT) A spawning stock level for managers to aim at in order to meet the management objective. The 'management objective' used for each river in England and Wales is that the stock should be meeting or exceeding its CL in at least four years out of five (i.e. >80% of the time), on average.

Microtag A coded wire tag 1.1 mm long and 0.25 mm diameter, typically inserted into the nasal cartilage (snout) of juvenile salmonids and detectable in live fish, but only readable after removal from the fish. Commonly abbreviated to CWT (coded wire tag).

Mixed stock fishery (MSF) A fishery that predominantly exploits mixed river stocks of salmon. The policy in England and Wales is to move to close coastal net fisheries that exploit predominantly mixed stocks where the capacity to manage individual stocks is compromised. Fisheries, including MSFs, operating within estuary limits are assumed to exploit predominantly fish that originated from waters upstream of the fishery; these fisheries are carefully managed to protect the weakest of the exploited stocks, guided by the decision structure and taking into account socio-economic factors and European Conservation status where applicable.

Multi-Sea-Winter (MSW) salmon An adult salmon that has spent two or more winters at sea.

NLO – Net Limitation Order Mechanism within the Salmon and Freshwater Fisheries Act, 1975 whereby the competent authority may apply to limit the number of nets or traps fishing a public fishery.

One-Sea-Winter (1SW) salmon An adult salmon that has spent one winter at sea (see also grilse).

Parr Juvenile salmon in the stage following fry until its migration as a smolt, Salmon parr are typically <16 cm long and have parr-marks (dark vertical bars) on the sides of the body.

Post-smolt Young salmon, at the stage from leaving the river (as smolts) until the middle of its first winter in the sea.

Precautionary approach A concept enshrined in Principle 15 of the Rio Declaration of the UN Conference on Environment and Development, which states: "In order to protect the environment, the precautionary approach shall be widely applied by States according to their capabilities. Where there are threats of serious or irreversible damage, lack of full scientific certainty shall not be used as a reason for postponing cost-effective measures to prevent environmental degradation."

Pre-fishery abundance (PFA) The PFA of salmon from England and Wales is defined as the number of fish alive in the sea on January 1 in their first sea winter. This is split between maturing (potential 1SW) and non-maturing (potential MSW) fish.

Production The assimilation of nutrients to produce growth in a population over a given period.

Radio tag An electronic transmitter which emits radio frequencies and is attached to (or inserted into) a fish to enable its position to be determined in freshwater.

Ranching The production of salmon through smolt releases with the intent of harvesting the total population that returns to freshwater (harvesting can include fish collected for broodstock).

Recruits The abundance of fish measured at a particular point in the life cycle, e.g. at the juvenile stages, the smolt stage, prior to the first fishery (recruitment to the fishery), or as returning spawners.

Reference point An estimated value derived from an agreed scientific procedure and/or model which corresponds to a state of the resource and/or of the fishery and can be used to assess stock status or inform management decisions.

River Basin District (RBD) A river basin or several river basins, together with associated coastal waters. For each River Basin District, the Water Framework Directive requires a River Basin Management Plan to be published. These are plans that set out the environmental objectives for all the water bodies within the River Basin District and how they will be achieved. The plans are based upon a detailed analysis of the pressures on the water bodies and an assessment of their impacts. The plans must be reviewed and updated every six years

Run The number of adult salmon ascending, or smolts descending, a river in a given year. The main smolt run takes place in spring, whereas adult salmon runs may occur in spring, summer, autumn or winter.

Special Areas of Conservation (SACs) An area designated under the EU Habitats Directive (92/43/EEC) giving added protection to identified species and habitats. Where salmon is a "qualifying species", additional protection measures are required specifically for salmon.

Salmonid A fish belonging to the family *Salmonidae*, which includes the Atlantic salmon (*Salmo salar*), brown trout / sea trout (*Salmo trutta*), charr (*Salvelinus alpinus*) and rainbow trout (*Oncorhynchus mykiss*).

Sea age The number of winters that a salmon has remained at sea.

Sea trout Anadromous form of the trout (*Salmo trutta*) from the post-smolt stage; the brown trout remains in freshwater throughout its life.

Sea Trout and Salmon Catchment Summary A document produced by the Environment Agency in consultation with partners which sets out the actions, either current or planned, for sea trout and salmon work within River Basin Districts as part of the WFD planning process. These summaries build on existing Salmon Actions Plans for principal salmon rivers but also cover sea trout and other rivers supporting salmon such as the Trent and Mersey which are recovering from historic industrial problems.

Site of Special Scientific Interest (SSSI) An area of land notified under the Wildlife and Countryside Act 1981 by the appropriate nature conservation body as being of special interest by virtue of its flora and fauna, geological or physiogeographical features.

Smolt The stage in the life cycle of a salmon when the parr undergo physiological changes, become silver in appearance and migrate to sea. Salmon smolts are typically 12–16 cm long and migrate to sea in spring.

Smolt age The number of winters, after hatching, that a juvenile salmon remains in freshwater prior to emigration as a smolt (this does not, therefore, include the winter in which the egg was laid).

Spring salmon Multi-sea-winter salmon which return to freshwater early in the year, usually before the end of May.

Special Area of Conservation (SAC) Protected Areas established for the protection of habitats or species under the Habitats Directive (92/43/EEC) (Special Areas of Conservation).

Stock A management unit comprising one or more salmon populations, which may be used to describe those salmon either originating from or occurring in a particular area. Thus, salmon from separate rivers are referred to as "river stocks". (N.B. Very large management units, such as the salmon exploited at West Greenland, which originate from many rivers, are often referred to as 'stock complexes').

Stocking The intentional release of fish into an ecosystem.

Sustainable use The use of a biological resource in a way and at a rate that does not lead to the long-term decline of its potential to meet the needs and aspirations of present and future generations. Sustainable use does not imply that abundance is constant.

ANNEX 3. Description of fishing methods (nets and fixed engines) used for taking salmon and migratory trout in England and Wales

A wide variety of nets and fixed engines are used to take salmon and sea trout. The term fixed engine is an ancient one used as a general descriptor of stationary fishing gears. The following are generalised descriptions of the gear used in England and Wales (for further details see Russell *et al.*, 1995); in practice there is considerable regional variation in the precise mode of operation of specific gears and in the dimensions and mesh sizes of the nets. These characteristics have generally evolved to suit local conditions and are regulated by local byelaws. As a result of measures over recent years to reduce exploitation of stocks, certain fishing gears listed here are now no longer in use (see below for details).

GILLING NETS:

Drift net A drift net consists of a sheet of netting which hangs from a floated head rope to a weighted foot rope and is designed to drift with the current or tide. Regional names include: hang, whammel, sling and tuck nets.

Coracle net These nets are only used in parts of Wales. Short lengths of trammel net are suspended between two coracles (small boats), which then drift downstream with the net strung across the current.

Trammel net Trammel nets are similar to drift nets but are modified by the addition of sheets of larger mesh netting on one or both sides of the net. Such nets are referred to as being 'armoured'. A fish striking a trammel net pushes the small mesh net through one of the large meshes in the adjoining net and is caught in the resultant pocket. Sometimes known locally as tuck nets (Severn Estuary). This gear is no longer fished.

Sling net The sling net is a type of drift net previously used exclusively on the River Clwyd in North Wales. It differs from other drift nets only in so far as the nets are permitted to carry weights (not exceeding 4 kg) at either end, designed to retard the drift. This gear is no longer fished.

Coastal net A loose term used to describe the nets used in the fishery off the East Anglian coast. In practice, various methods of fishing have been employed, including drift nets and beach seine nets (which may take fish by gilling).

SWEEP/ENCIRCLING NETS:

Seine net A seine net (also known as a draft or draw net) consists of a wall of netting with a weighted foot rope and floated head rope. One end is held on the shore while the rest is paid out from a boat to enclose an area of water between two points on the shore. The net is then retrieved and any fish enclosed drawn up onto the shore. Seine nets normally operate within estuaries, although some are also fished off coastal beaches.

Wade net A wade net consists of a short (~30 m) single sheet of netting which is attached to a pole at each end, and is pulled along the foreshore parallel to the beach by two men, one wading and the other on the beach. Nets are 'beached' at regular intervals, or when a fish strikes, in much the same way as a seine net.

FIXED ENGINES:

Basket trap This is a type of fixed engine which has only been used on the River Conwy in North Wales. It consists of a metal basket set between two boulders, which is designed to catch salmon and sea trout which fall back when attempting to ascend a small waterfall. This gear is not fished at the present time.

Compass net These nets are operated from a boat held stationary against the current. A net is hung between two long poles lashed together in a V-shape and held over the side of the boat so that the net streams out underneath the boat. When a fish strikes the net, the poles are pivoted upwards with the aid of counter-balancing weights.

Crib (or Coop) These ancient fixed engines consist of stone buttresses set across a river, the gaps between the buttresses being filled by box-like traps made of either wood or metal with in-scale entrances. The River Eden cribs were understood to have been first built by monks in 1133 A.D.; the River Derwent cribs are of more recent construction.

Putchers (and Putts) Putchers are wickerwork or metal conical baskets which, when erected on stages, form putcher ranks (containing up to 800 putchers). This type of fixed engine is peculiar to the Bristol Channel and is dependent upon the high turbidity and large tidal range which occurs in this area. Each putcher has a mouth from 1 to 1.5 m wide, tapering to a narrow point which will prevent fish of moderate size from passing through. A netting leader is often used to guide fish into the putchers. Putts are of similar design to putchers, only larger.

T-net T-nets are fixed engines operated close to the shore, usually in specific berths. They comprise a 'leader', usually about 200 m in length, stretching out from the beach to a 'headpiece', which contains two traps with funnel entrances. Some fish may become enmeshed or entangled in the leader of the net, but the majority are taken, free-swimming, in the traps.

'T or J'-net 'T or J'-nets consist of plain sheets of netting on a floated head rope which hang vertically in the water by means of a weighted foot rope and are set from the shore in the shape of a 'T', inverted 'J' or 'P'. These nets are usually operated as fixed engines, held stationary by means of weights, anchors or stakes, but can also be drifted with weights used to retard the rate of movement. Fish can only be caught in a 'T or 'J' net by becoming enmeshed or entangled in the walls of the net.

HAND-HELD NETS:

Haaf or heave net These one-man-operated nets are operated exclusively in the North West Region. The gear consists of a rectangular net hung from a horizontal wooden beam up to 5.5 m wide. A central pole permits the netsmen to stand in the tideway holding the net facing the current with the netting streaming behind him. The net is lifted when a fish strikes the net. It is usual for several netsmen to work together line-abreast, moving along the line as the tide rises/falls.

Lave (or dip) net Lave nets are hand-held, one-man-operated nets consisting of a large Y-shaped wooden frame supporting a net, similar in design to an angler's landing net, but measuring up to 2 m across. The netsman actively stalks fish in estuary pools or shallows at low tide. This gear is only used in the Severn Estuary and parts of the North West Region.

ANNEX 4. North Atlantic Salmon Conservation Organisation

The North Atlantic Salmon Conservation Organisation (NASCO) was established in 1984 following calls for international co-operation on the management of salmon stocks. It is an international body with the objective of contributing through consultation and co-operation to the conservation and rational management of salmon stocks taking account of the best available scientific evidence. The Contracting Parties to the NASCO Convention are currently: Canada; Denmark (in respect of the Faroe Islands and Greenland); European Union; Norway; the Russian Federation; and the USA. Iceland was previously also a Contracting Party, although has currently relinquished this position. Much of the business of the organisation is conducted by three regional Commissions: the North American Commission; the North East Atlantic Commission; and the West Greenland Commission. One of the main functions of these Commissions is to propose regulatory measures for fisheries of one Party to the NASCO Convention, which exploit salmon originating in the rivers of other Parties. The main fisheries of relevance for the management of European stocks are those operated on the west coast of Greenland and within Faroese waters; tables summarising the regulatory measures agreed by NASCO for these fisheries are provided below. To support this process, NASCO obtains scientific advice on the status of salmon stocks and fisheries and their management from the International Council for the Exploration of the Sea (ICES) (see Annex 5). The list of questions posed by NASCO to ICES for consideration in the latest assessment year is provided in the annual assessment report.

In 1998, NASCO and its Parties agreed to apply a Precautionary Approach to the conservation, management and exploitation of salmon in order to protect the resource and preserve the environments in which it lives. To this end, NASCO has adopted a number of Resolutions and Agreements which address the Organisation's principal areas of concern for the management of salmon stocks. In 2004, NASCO initiated a review of its activities, and as part of this 'Next Steps' process, determined that it should develop a simpler and more transparent approach for reporting on progress on the implementation of its agreements. NASCO therefore agreed that each relevant jurisdiction should develop an Implementation Plan for the period 2006-2011 to describe its proposed approach for meeting the objectives of NASCO's agreements. Following this, jurisdictions were also requested to prepare Focus Area Reports (FARs) to provide a more in-depth assessment of measures they are taking or planning to take to implement NASCO Agreements, Resolutions, and Guidelines in relation to Fishery Management (completed in 2008), Protection, Restoration and Enhancement of Salmon Habitat (completed in 2009), and Aquaculture and associated activities (completed in 2010). In 2012, NASCO agreed that jurisdictions should develop a second round of Implementation Plans for the period 2013-18, and these are available on the NASCO website at:

http://www.nasco.int/implementation_plans_cycle2.html.

Summary of Regulatory Measures agreed by NASCO for the West Greenland Salmon Fishery

Year	Allowable catch (tonnes)	Comments/other details in the measures
1984	870	
1985	–	Greenlandic authorities unilaterally established quota of 852t.
1986	850	Catch limit adjusted for season commencing after 1 August.
1987	850	Catch limit adjusted for season commencing after 1 August.
1988–1990	2520	Annual catch in any year not to exceed annual average (840t) by more than 10%. Catch limit adjusted for season commencing after 1 August.
1991	–	Greenlandic authorities unilaterally established quota of 840t.
1992	–	No TAC imposed by Greenlandic authorities but if the catch in first 14 days of the season had been higher compared to the previous year a TAC would have been imposed.
1993	213	An agreement detailing a mechanism for establishing annual quota in each of the years 1993 to 1997 was adopted by the Commission.
1994	159	
1995	77	
1996	–	Greenlandic authorities unilaterally established a quota of 174t.
1997	57	An addendum to the 1993 Agreement was agreed by the Commission.
1998	Internal consumption fishery only	Amount for internal consumption in Greenland has been estimated in the past to be 20t.
1999	Internal consumption fishery only	Amount for internal consumption in Greenland has been estimated in the past to be 20t.
2000	Internal consumption fishery only	Amount for internal consumption in Greenland has been estimated in the past to be 20t. A Resolution Regarding the Fishing of Salmon at West Greenland was agreed by the Commission.
2001	28–200	Under an <i>ad hoc</i> management programme the allowable catch will be determined on the basis of CPUE data obtained during the fishery.
2002	20–55	Under an <i>ad hoc</i> management programme the allowable catch will be determined on the basis of CPUE data obtained during the fishery.
2003–2008	Internal consumption fishery only	Amount for internal consumption in Greenland has been estimated in the past to be 20t.
2009–2011	Internal consumption fishery only	Amount for internal consumption in Greenland has been estimated in the past to be 20t.
2012–2014	Internal consumption fishery only	Amount for internal consumption in Greenland has been estimated in the past to be 20t.
2015–2017	Internal consumption fishery only. Greenland unilaterally committed limit the total annual catch for all components of the fishery to 45t in 2015, 2016 and 2017.	<p>The fishery will open no earlier than 1 August and close no later than 31 October each year.</p> <p>Any overharvest in one year will result in an equal reduction in the catch limit the following year.</p> <p>Efforts will be made to identify and implement temporal or spatial harvest restrictions that would provide increased protection for weaker stocks.</p> <p>Greenland will further improve the monitoring, management control and surveillance of its salmon fishery in accordance with the Plan for Implementation and Control Measures in the Salmon Fishery at West Greenland with the objective of achieving full catch accountability.</p> <p>All Members of the Commission will implement the six tenets.</p> <p>Greenland will inform NASCO, in a timely manner, of any modifications to the management of the West Greenland salmon fishery, of the outcome of the 2015, 2016 and 2017 fisheries and of progress with the implementation and effectiveness of its Plan for Implementation of Monitoring and Control Measures in the Salmon Fishery at West Greenland.</p> <p>States of origin will explore opportunities to share experiences with Greenland on monitoring, management control and surveillance in the salmon fishery.</p> <p>The Commission agreed to review the measure prior to the 2016 fishery.</p> <p>The measure will apply in 2016 and 2017 unless the Framework of Indicators shows that a reassessment of the multi-annual advice provided in 2015 is warranted.</p>

Summary of Regulatory Measures/Decisions agreed by NASCO for the Faroese Salmon Fishery

Year	Allowable catch (tonnes)	Comments/other details in the measures/decisions
1984–85	625	
1986	–	
1987–89	1790	Catch in any year not to exceed annual average (597t) by more than 5%.
1990–91	1100	Catch in any year not to exceed annual average (550t) by more than 15%.
1992	550	
1993	550	
1994	550	
1995	550	
1996	470	No more than 390 tonnes of the quota to be allocated if fishing licences issued.
1997	425	No more than 360 tonnes of the quota to be allocated if fishing licences issued.
1998	380	No more than 330 tonnes of the quota to be allocated if fishing licences issued.
1999	330	No more than 290 tonnes of the quota to be allocated if fishing licences issued.
2000	300	No more than 260 tonnes of the quota to be allocated if fishing licences issued.
2001–2003	No quota set	It is the intention of the Faroese authorities to manage the fishery in a precautionary manner with a view to sustainability, and to make management decisions with due consideration to the advice from ICES concerning status of stocks contributing to the fishery.
2004–2006	No quota set	It is the intention of the Faroese authorities to manage the fishery on the basis of the advice from ICES concerning status of stocks contributing to the fishery in a precautionary manner with a view to sustainability and taking into account relevant factors such as socio-economic needs and other fisheries on mixed stocks.
2007	No quota set	It is the intention of the Faroese authorities to manage any salmon fishery on the basis of the advice from ICES regarding the stocks contributing to the Faroese salmon fishery in a precautionary manner and with a view to sustainability, taking into account relevant factors such as socio-economic needs.
2008	No quota set	It is the intention of the Faroese authorities to manage any salmon fishery on the basis of the advice from ICES regarding the stocks contributing to the Faroese salmon fishery in a precautionary manner and with a view to sustainability, taking into account relevant factors such as socio-economic needs.
2009	No quota set	It is the intention of the Faroese authorities to manage any salmon fishery on the basis of the advice from ICES regarding the stocks contributing to the Faroese salmon fishery in a precautionary manner and with a view to sustainability, taking into account relevant factors such as socio-economic needs.
2010	No quota set	It is the intention of the Faroese authorities to manage any salmon fishery on the basis of the advice from ICES regarding the stocks contributing to the Faroese salmon fishery in a precautionary manner and with a view to sustainability, taking into account relevant factors such as socio-economic needs.
2011	No quota set	It is the intention of the Faroese authorities to manage any salmon fishery on the basis of the advice from ICES regarding the stocks contributing to the Faroese salmon fishery in a precautionary manner and with a view to sustainability, taking into account relevant factors such as socio-economic needs.
2012	No quota set	It is the intention of the Faroese authorities to manage any salmon fishery on the basis of the advice from ICES regarding the stocks contributing to the Faroese salmon fishery in a precautionary manner and with a view to sustainability, taking into account relevant factors such as socio-economic needs.
2013–2015	No quota set	It is the intention of the Faroese authorities to manage any salmon fishery on the basis of the advice from ICES regarding the stocks contributing to the Faroese salmon fishery in a precautionary manner and with a view to sustainability, taking into account relevant factors such as socio-economic needs.
2015/16–2017/18	No quota set	It is the intention of the Faroese authorities to manage any salmon fishery on the basis of the advice from ICES regarding the stocks contributing to the Faroese salmon fishery in a precautionary manner and with a view to sustainability, taking into account relevant factors such as socio-economic needs. The Decision will apply in 2016/17 and 2017/18 unless the Framework of Indicators shows that a reassessment of the multi-annual advice provided in 2015 is warranted.

Note: The quotas for the Faroe Islands detailed above for the period 1984–2000 were agreed as part of effort limitation programmes (limiting the number of licences, season length and maximum number of boat fishing days) together with measures to minimise the capture of fish less than 60cm in length. The measure for 1984/85 did not set limits on the number of licences or the number of boat fishing days.

ANNEX 5. International Council for the Exploration of the Sea

The International Council for the Exploration of the Sea (ICES) provides biological information and advice on a wide range of fish stocks in order to help fisheries managers maintain viable fisheries within sustainable ecosystems. Information is compiled and assessments are conducted by Working Groups, which are comprised of national experts on the specific fish stocks. The Working Group reports are passed to the Advisory Committee (ACOM) for peer review and to provide the formal advice to managers. The advice may take many forms, but in general it involves: assessments of stock dynamics; evaluation of the status of the stocks; projections of various stock parameters into the future; and management options. For Atlantic salmon, ICES provides advice relating to a list of questions posed by NASCO each year; the questions for consideration in the latest assessment year are provided in the latest annual assessment report. The assessment of salmon stocks and their fisheries presents particular problems to the ICES scientists both because of the highly migratory nature of the fish and because they comprise a large number of distinct river stocks which must, to some extent at least, be managed separately.

Description of the ICES assessment methodology for England and Wales

The model that ICES uses to estimate the pre-fishery abundance (PFA) for North East Atlantic Commission (NEAC) countries endeavours to provide our best interpretation of what the available catch and effort data tell us about changes in the status of total national stocks of salmon over the past four decades.

The model first estimates the returns of salmon to freshwater, and then back-calculates the numbers of fish that must have been alive in the sea to generate these returns. The numbers of returning fish are estimated using the catch data for each country, which are raised to take account of non-reported catches and exploitation rates for 1SW and MSW fish. These values are then further raised to take account of catches in the distant water fisheries and natural mortality between January 1 in the first sea winter and their return to homewaters. Ranges of values are used for some of the input data in order to obtain a measure of the uncertainty in the PFA estimates. In order to run the NEAC PFA model, each country requires time-series (beginning in 1971) of catch in numbers, non-reporting rates and exploitation rates for 1SW and MSW salmon.

For England and Wales, nominal catches have been derived from the catch returns submitted by netmen and anglers and split into 1SW and MSW categories using two different methods. Over the period 1992 to the present, monthly age-weight keys derived from salmon caught in the River Dee trap have been used to estimate the age of all rod-caught fish where a weight and date of capture have been provided. This has then been scaled up to the total catch (rods and nets combined) on a pro-rata basis. In earlier years (1971-1991), the age composition of the total catch has been estimated using the mean weight of the fish caught and the mean weight of 1SW and MSW salmon recovered in tagging programmes. Estimates of unreported and illegal catches have been made on the basis of consultation with regional fisheries personnel and according to the approach described in Section 4.6.

As the contribution of farmed and ranched salmon to the national England and Wales catch is negligible, the occurrence of such fish is ignored in the assessments of the status of national stocks. However, a large proportion of the fish taken in the north-east coast fishery are destined for Scottish rivers, and these are deducted from the returning stock estimate for England and Wales and added to the data for Scotland in the ICES assessment. This proportion is estimated

to have declined from 95% of the north-east net catch in the early part of the time-series to 75% in the late 1990s and to around 65% since 2003. This reflects both the steady improvement in the status of the stocks in north-east England and the accelerated phase-out of the fishery in 2003. The latter resulted in a major overall reduction in the fishery, with the majority of the remaining netsmen now fishing close inshore using T- or J-nets. Previous tagging studies have shown that these inshore nets exploit a much higher proportion of local fish (Anon., 1991) and a recent genetic study has confirmed that the current estimate is realistic (see Section 7.7 for further details).

Exploitation rates for a number of monitored fisheries in England and Wales are derived annually. National exploitation rates have then been estimated by deriving time-series of 'standard fishing units' employed in the salmon fisheries for the period 1971 to the present. For the period 1971 to 1997, these are calculated from the numbers of licences issued weighted by their relative catching power, which is estimated from historic CPUE data; and for the period 1998 to the present, they are calculated from the numbers of days fished by different net categories weighted in the same way. The annual exploitation rates are then estimated by referencing the number of 'standard fishing units' employed over the two periods relative to average age-specific exploitation estimates derived for the 1997 and 1998 seasons. Finally, ICES has agreed to apply a natural mortality rate of 3% per month in back-calculating the PFA of salmon in the sea, on the basis of studies undertaken on a range of stocks (ICES, 2002 and 2003).

ANNEX 6. European Directives and other measures affecting salmon management

Habitats Directive

The main aim of the EU Habitats Directive 92/43/EEC, on Conservation of Natural Habitats and of Wild Fauna and Flora is to promote the maintenance of biodiversity. It stipulates that Member States take measures to maintain or restore natural habitats and wild species to favourable conservation status introducing robust protection for those habitats and species of European importance. To comply with this Directive, a number of rivers in England and Wales have been designated Special Areas of Conservation (SACs) because they support important populations of vulnerable qualifying species.

The following rivers in England and Wales are SACs and have salmon as a “qualifying species”, which confers additional protection measures specifically for salmon in these rivers and associated on-line lakes:

Southern Region: Itchen.

South West Region: Hampshire Avon*, Camel, Dartmoor Headwaters (Dart, Teign, Erme, Taw, Yealm, and Tavy including its tributary the Walkham)

Wales: Wye*, Usk*, Teifi*, Dee* (and Bala Lake), Gwyrfai* (and Llyn Cwellyn) and Eden (West Gwynedd - part of the Mawddach catchment).

North West Region: Derwent* (and Bassenthwaite Lake), Eden* and Ehen.

For eight of these rivers (marked *), Atlantic salmon are recognised as a primary species for SAC designation purposes.

Water Framework Directive (WFD)

The European Water Framework Directive (Directive 2000/60/EC) came into force on 22 December 2000 and became part of UK law in December 2003. Section 11.1 provides further information and web links for further information.

Data Collection Framework

The Data Collection Framework (DCF) is an EU programme established under EU Regulation 199/2008 for the collection, management and use of data to provide a sound basis for scientific assessments of fish stocks. The framework establishes rules on the collection and management of biological, technical, environmental and socio-economic data for the fisheries sector, and the use of these data for scientific analyses. The framework was originally developed for marine fisheries, but commercial and recreational fisheries for salmon (and eel) have been included in the legislation since 2007.

The framework provides part-funding to support data collection, on the basis that these data are collected to specified, rigorous standards of method and quality to meet the needs of national and international bodies such as ICES in the provision of scientific advice relating to fish stocks and fisheries. In England and Wales, the DCF presently contributes funding towards the collection

of catch statistics, juvenile salmon surveys, and the 'Index Rivers' monitoring programmes, which provide estimates of marine survival and exploitation rates. The framework also provides partial funding to support UK scientists to attend annual assessment working groups at ICES, which in turn provide advice to NASCO on the assessment and management of Atlantic salmon throughout the North Atlantic. The DCF provisions are currently under review and future data collection requirements being developed; these are likely to be implemented in 2017.

United Kingdom Post-2010 Biodiversity Framework

The 'UK Post-2010 Biodiversity Framework' was published in July 2012 and succeeded the UK Biodiversity Action Plan (UK BAP). Salmon was added to the list of priority species under the UK BAP in 2007. This gave added emphasis to efforts to conserve and improve salmon populations and this still applies. Listing brings with it a need for programmes to be developed and delivered by partnerships of statutory, voluntary, academic and business organisations and for status and trends to be recorded and reported. The latest version of the England Biodiversity Strategy to 2020 can be found [here](#). More information about biodiversity in Wales can be found [here](#).

ANNEX 7. Salmon management procedures/developments in England and Wales

Conservation Limits and Management Targets

Setting conservation limits

The use of conservation limits (CLs) in England and Wales has developed in line with the requirement of ICES and NASCO to set criteria against which to give advice on stock status and the need to manage and conserve individual river stocks. CLs indicate the minimum desirable spawning stock levels below which stocks should not be allowed to fall. The CL is set at a stock size below which further reductions in spawner numbers are likely to result in significant reductions in the number of juvenile fish produced in the next generation.

Two relationships are required to derive the CLs:

- (i) a **stock-recruitment curve** – defining, for the freshwater phase of the life cycle, the relationship between the number of eggs produced by spawning adults (stock) and the number of smolts resulting from those eggs (recruits).
- (ii) a **replacement line** – converting the smolts emigrating from freshwater to surviving adults (or their egg equivalents) as they enter marine homewaters. This relationship requires an estimate of the survival rate at sea.

The model used to derive a stock-recruitment curve for each river assumes that juvenile production is at a 'pristine' level for that river type (i.e. is not affected by adverse water quality, degraded physical habitat, etc.).

Similarly, in deriving the replacement line, marine survival rates for most river stocks were assumed to be equivalent to the rates estimated on UK monitored rivers (such as the North Esk) in the 1960s and 1970s. Default survival values recommended for this purpose were 25% for 1SW salmon and 15% for MSW fish (Environment Agency, 1998). However, that period is thought to be one of high sea survival, and new default values of 11% for 1SW salmon and 5% for MSW fish, which are more representative of sea survival over the last 20 years, were introduced by the Environment Agency in April 2003 (Environment Agency, 2003b).

These rates have now been applied in calculating CLs for all the 64 rivers with Salmon Action Plans (SAPs). Since 2003, the CLs for all principal salmon rivers for which egg deposition estimates are assessed annually have incorporated the new lower marine survival estimates. The net effect of these changes was to reduce the CLs: the scale varied from river to river, but resulted in a 26% reduction, on average, in England and Wales from values used prior to 2003.

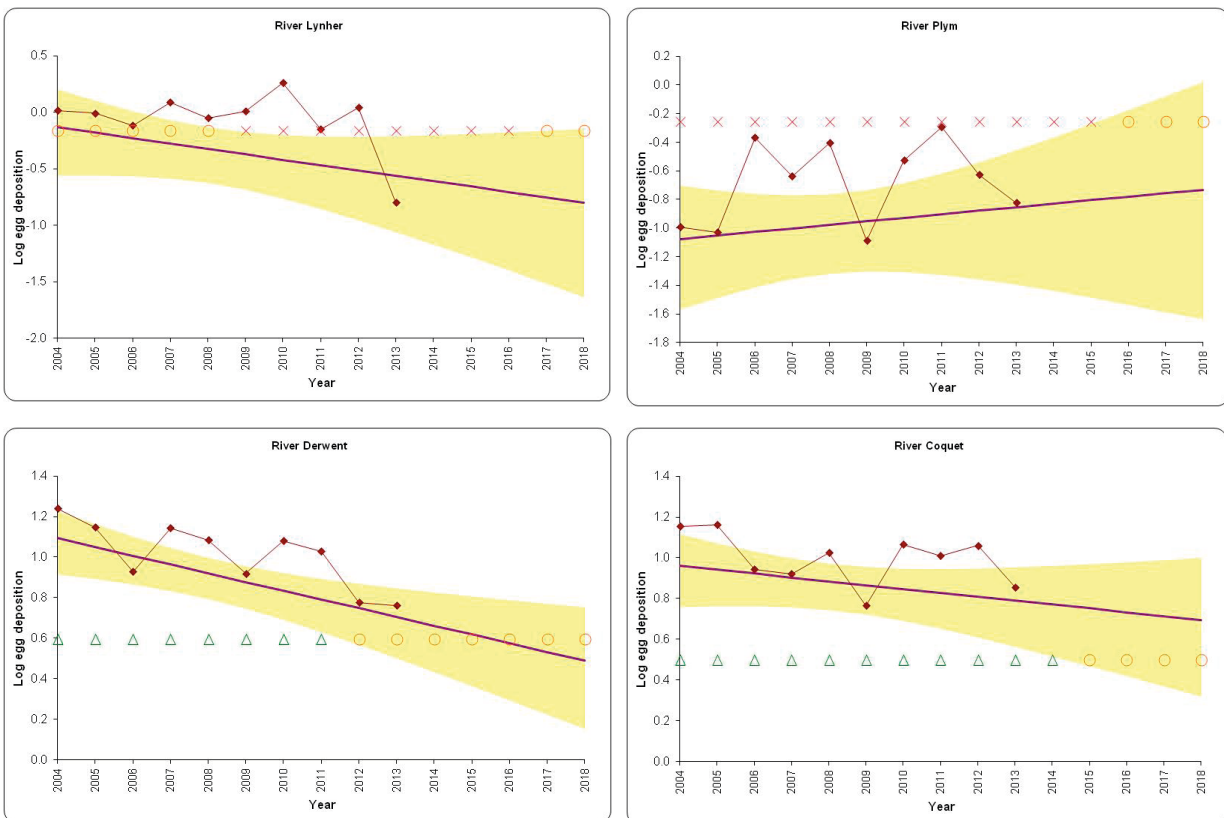

Introducing marine survival rates which are intended to be closer to those currently experienced by UK salmon stocks will reduce the effect of high mortality at sea as a cause of failing CLs. This will help managers focus on other issues over which they have more control (e.g. poor environmental quality in-river, over-exploitation by net and rod fisheries, etc.) when compliance failure occurs. The reduction in CLs means, however, that lower levels of spawning escapement are accepted before the stock is considered to be threatened. The Environment Agency also uses the 'management objective' for each river (e.g. in reviewing management actions and

regulations) that the stock should be meeting or exceeding its CL in at least four years out of five, on average. This management objective is built into statistical procedures for assessing compliance with CLs (below).

Compliance assessment

The performance of salmon stocks in England and Wales is assessed using a compliance scheme designed to give an early warning that a river has fallen below its CL. An approach introduced in 2004 provides a way of summarising the performance of a river’s salmon stock over the last 10 years (including the current year), in relation to its CL. Bayesian regression analyses are applied to egg deposition estimates from the last 10 years, on the assumption that there might be an underlying linear trend over the period. The method fits a 20 percentile regression line to the data and calculates the probability that this regression line is above the CL, and thus that the CL will be exceeded four years out of five (the management objective). If there is a low probability (< 5%) that the 20 percentile regression line is above the CL, the river fails to comply (i.e. is regarded ‘at risk’). If the probability is high (> 95%), the river complies in that year (i.e. is ‘not at risk’), whereas between these probability values we cannot be certain of the stock status (the river is assessed as either ‘probably at risk’ (5% < p < 50%) or ‘probably not at risk’ (50% ≤ p < 95%)). The results are in broad agreement with the previous compliance scheme used prior to 2004. The current scheme also allows the 20 percentile regression line to be extrapolated beyond the current year in order to project the likely future performance of the stock relative to its CL, and so assess the likely effect of recent management intervention and the need for additional measures.

The compliance plots for the Rivers Lynher, Plym, Derwent and Coquet for the years 2004-2013 are shown below as examples. These include individual egg deposition estimates (black dots on the graphs) for these years, the 20 percentile regression lines and (shaded) 90% confidence intervals, and the CL lines (represented by up to three symbols: X, O and Δ).

When the upper bound (95 percentile) of the regression line confidence interval is below the CL line the river is judged to be failing its CL (i.e. there is a $\geq 95\%$ probability of failure or the river is 'at risk'). For example, this is the case on the Lynher from 2009 to 2016 and the Plym from 2004 to 2015 and is indicated by the X symbol on the CL line. When the lower bound (5 percentile) of the regression line confidence interval is above the CL line the river is judged to be passing its CL (i.e. there is a $\leq 5\%$ probability of failure and the river is 'not at risk'). This is the case on the Derwent from 2004 to 2011 and the Coquet from 2004 to 2014 and is indicated by the Δ symbol on the CL line. For all other years on these rivers, the shaded confidence interval of the regression line overlaps the CL line and so the status of the river is judged as 'uncertain' (i.e. the probability of failure is $>5\%$ but $<95\%$, and the river is either 'probably at risk' or 'probably not at risk'). This is the case on the Lynher from 2004 to 2008 and in 2017 to 2018, on the Derwent from 2012, the Coquet from 2015 and on the Plym from 2016 and is indicated by the O symbol on the CL line.

Egg deposition estimates for a river may be consistently above the CL but status may still be uncertain. This is the case on the Coquet from 2015 and the Derwent from 2012 (O symbol on the CL line). In part, this reflects the marked year-to-year variation in egg deposition estimates on these rivers, which produces a broad confidence interval around the regression lines, but also arises because of the slope of the trend line and the increasing uncertainty associated with all regressions once extrapolated beyond the data set.

As well as providing an assessment of the status of a river in relation to its CL, the direction of the trend in the 10-year time-series of egg deposition estimates and its statistical significance may also serve as an important indicator of the need to take management action and of the degree of intervention required. Thus, a clear negative trend would give additional cause for concern.

The Management Target (MT) for each river is a spawning stock level for managers to aim at, to ensure that the objective of exceeding the CL is met four years out of five in the long run (i.e. 80% of the time). The value of the MT has been estimated using the standard deviation (SD) of egg deposition estimates for the last 10 years, where: $MT = CL + 0.842 * SD$. The constant 0.842 is taken from probability tables for the standard normal distribution, such that the CL forms the 20 percentile of a distribution, the average (or 50 percentile) of which equates to the MT.

CLs and MTs form only one part of the assessment of the status of a stock, and management decisions are never based simply on a compliance result alone. Because stocks are naturally variable, the fact that a stock is currently exceeding its CL does not mean that there will be no need for any management action. Similarly, the fact that a stock may fall below its CL for a small proportion of the time may not mean there is a problem. Thus, a range of other factors are taken into account, particularly the structure of the stock and any evidence concerning the status of particular stock components, such as tributary populations or age groups, based for example on patterns of run timing and the production of juveniles in the river sub-catchments. These data are provided by a programme of river catchment monitoring.

The Environment Agency and Natural Resources Wales are continuing to review and revise their procedures for using reference points and other modelling techniques in the assessment and management of salmon stocks. Work is underway to better reflect real exploitation rates, where these are available, in stock assessments, and to review the balance between use of default (generic) and river-specific data. The assessment approach described above is now incorporated into the national decision structure (see below) for guiding decisions on fishery regulations.

The Decision Structure for developing fishing controls in England and Wales

The compliance assessment approach described above for determining the performance of each salmon river is also incorporated into a national decision structure for guiding decisions on the need for fishery regulations. The 'Decision Structure' is applied annually to each salmon river in April following the annual stock assessments. Fishery managers for each river are then advised of these assessments and the outcome of applying the 'Decision Structure'. They then begin the process of deciding what changes in regulation are appropriate as guided by the Decision Structure outputs. Recovering rivers that do not yet have CLs set are deemed to be 'at risk'.

The 'Decision Structure' is shown in the schematic flow chart below, together with explanatory notes for its use.

The Decision Structure – Developing fishing controls for salmon fisheries in England and Wales

Notes to accompany Decision Structure

1. Initial stage - stock assessment (red boxes)

This is the assessment of the probability that the salmon river will be meeting its CL four years out of five (the management objective) in five years' time. The information to answer these questions comes from the annual assessment process outlined in Section 8, with the latest results available in the most recent annual assessment report.

2. Second stage – initial screening for potential options (blue boxes)

This stage screens options appropriate to those rivers that have a **<50% probability of failing the management objective** taking into consideration socio-economic concerns and stakeholder support. Management options that would not be supported by stakeholders can be ruled out. One of the possible options is to 'do nothing'.

For rivers where there is **>50% probability of failing the management objective**, all options must be carried through to the next (evaluation) stage.

3. Third stage - option evaluation (purple boxes)

The purpose of this stage is to set out and evaluate options to realise the required changes in exploitation.

For rivers where $50\% \leq p < 95\%$ (where p = probability of failing the management objective) **and the trend is down** and with an annual catch of >20 salmon and C&R rate $< 90\%$, then voluntary catch and release (C&R) will be promoted for 1 year. If this fails to significantly improve C&R rates, mandatory C&R or closure of the fishery will be considered. Protected rivers such as SACs (Special Areas of Conservation) are given particular emphasis

For rivers where the above criteria apply, except that the annual mean salmon catch is <20 salmon, voluntary measures will be promoted

For rivers where $p > 95\%$ (i.e. the management objective is clearly being failed) and with an annual catch of >20 salmon and a C&R rate $< 90\%$, then voluntary C&R will be promoted for 1 year. If this fails to significantly improve C&R, mandatory C&R or closure of the fishery will be considered.

For rivers where $p \leq 95\%$ for 5 consecutive years (i.e. the management objective is clearly being met), the possibility of relaxing controls including on nets will be considered if stakeholders agree.

Rivers that are recovering from historical degradation that do not yet have CLs set are deemed to have a $>95\%$ probability that they are failing unless there is better information available. Fishers on such rivers are encouraged to practice 100% C&R at the same time as regulators and partner organisations work on the necessary environmental improvements. If the potential for these rivers is greater than an average rod catch of 20 salmon, then mandatory C&R is considered throughout the season as an interim measure. However, controlled development of fisheries may be permitted on these rivers in parallel with the recovery of stocks.

4. Final stage – selection and implementation (green boxes)

The final stage of the Decision Structure is the selection and implementation of the appropriate regulatory action.
