PART B: INFORMATION ABOUT THE RELEASE APPLICATION TO BE INCLUDED ON THE PUBLIC REGISTER

B1 The name and address of the applicant

Rothamsted Research,
West Common,
Harpenden
Hertfordshire,
AL5 2JQ
UK

B2 A general description of the genetically modified organisms in relation to which the application is being made

The organism to be released is the oilseed *Camelina sativa* (hereafter referred to as "Camelina") and we have used genetic modification to introduce into this plant the capacity to produce the omega-3 long chain polyunsaturated fatty acids eicosapentaenoic acid (EPA) and docosahexaenoic acid (DHA). The synthesis of these health-beneficial fatty acids has been engineered so as to only occur in the seeds of the GM Camelina. Similarly, GM Camelina plants have been engineered to accumulate the ketocarotenoid compound, astaxanthin. Astaxanthin is considered to be an antioxidant, and also has a distinctive pink pigment which is used in fish-farming diets. Again, the synthesis and accumulation of astaxanthin has been engineered to only occur in the seeds of the GM Camelina. In a third iteration, the EPA and DHA accumulating plants were crossed in the laboratory with the astaxanthin-accumulating plants, to produce progeny which contained both traits.

The GM Camelina plants have been engineered with the novel capability to accumulate the non-native omega-3 long chain polyunsaturated fatty acids EPA (eicosapentaenoic acid) and DHA (docosahexaenoic acid) through the introduction of the biosynthetic genes for these fatty acids. Such genes are normally only found in marine microbes such as microalgae and diatoms and some oomycetes and lower plants. Synthetic genes (meaning that the native DNA sequences have been codon-optimized and chemically synthesized) from EPA- & DHA-accumulating organisms have been integrated into the genome of Camelina, under the control of seed-specific promoters.

Two different constructs are described in this application. In the first example (B7.2), synthetic genes derived from activities present in the picoalgae *Ostreococcus tauri*, the moss *Physcomitrella patens*, the Thraustochytriaceae *Thraustochytrium*, the oomycetes *Phytophora infestans* and *Phytophora sojae* and the diatom *Thalassiosira pseudonana* have each been linked to seed-specific regulatory sequences and introduced into the genome of Camelina to direct the synthesis of both EPA and DHA only in seeds. In a second iteration (DHA2015.1), the activity and associated synthetic gene (that from *Thalassiosira pseudonana)* was replaced with an identical activity (but different synthetic gene), derived from the picoalga *Ostreococcus* RCC809. In other respects, B7.2 and DHA2015.1 are identical. Both constructs direct the synthesis of EPA and DHA levels higher than previously evaluated in the field.

Similarly, construct ASX-A2 contains synthetic genes for the astaxanthin biosynthetic pathway, derived from sequences present in the higher plants *Adonis aestivalis* and *Zea mays.* All sequences were individually been linked to seed-specific regulatory sequences and introduced into the genome of Camelina to direct the synthesis of astaxanthin only in seeds.

Two constructs (B7.2, DHA2015.1) also contain the visual reporter protein DsRed, which allows for the simple identification of GM Camelina seeds. The DsRed protein is derived from the marine coral species *Discosoma* sp and has been codon-optimised for expression in plants. One construct (ASX-A2) contains the selectable marker *bar* which confers resistance to the compound bialaphos, which was used to select GM Camelina plants in the laboratory. Bialaphos (and related compounds which form the active ingredient of specific Class H herbicides) will not be used in the course of this field trial. The genetic cross between ASX-A2 and B7.2 contains all of the genes and associated activities described above.

B3 The location at which the genetically modified organisms are proposed to be released

The location of the field trial is an agricultural area forming part of an experimental farm at Rothamsted Research, Harpenden, UK and at grid reference TL 120130. The area for the proposed field trial, including controls and spacing between GM plots will cover 50mx50m for both years.

B4 The purpose for which the genetically modified organisms are proposed to be released (including any future use to which they are intended to be put).

The purpose of this experimental trial is to determine the performance of these different GM Camelina iterations in the field, with respect to oil composition and oil quantity, seed-specific accumulation of astaxanthin and also to assess any additional phenotypic and agronomic variations, including to any arising as a consequence of the stacking of the two traits in the genetic cross. Specific questions to be examined are:

- Do the GM Camelina plants efficiently accumulate EPA and DHA in seed oil in the field?
- Do the GM Camelina plants efficiently accumulate astaxanthin in their seeds in the field?
- Do the GM Camelina plants efficiently accumulate both EPA/DHA and astaxanthin in their seeds the field?
- Do the GM Camelina plants still accumulate total seed oil to appropriate levels?
- Is there any further alteration to the lipidome of field-grown GM Camelina?
- Is there any difference between lines the different lines (including the genetic cross) in terms of agronomic performance?

- Is there any advantage or disadvantage to the GM Camelina plants in terms of field-based performance?

B5 The intended dates of the release.

The exact timing of sowing of the trial will depend upon weather conditions at the time. The field trial start date will be in April 2016 and the plants will be harvested in Aug or Sept the same year. We intend to repeat the trial with the specified four GM lines in 2017.

B6 The environmental risk assessment.

The four GM Camelina lines are indistinguishable from the non-GM equivalent except for the modified composition of their seeds, in particular by the presence of either omega-3 long chain polyunsaturated fatty acids EPA and DHA and/or astaxanthin. This modified composition is found only in the seeds of the GM Camelina and is absent from all other vegetative tissues (e.g. leaves, roots, stems). The gene donor organisms are not known to be pathogenic or allergenic to humans, and none of the genes under investigation, or the selectable or visual marker genes, are expected to result in the synthesis of products that are harmful to humans, other organisms or the environment. Any unknown hazards arising from the expression and ingestion of foreign proteins will not occur since the Camelina plants will not be consumed by humans.

The probability of GM Camelina seeds escaping from the trial site or the transfer of inserted characteristics to sexually-compatible species outside the trial area is estimated as very low. Camelina seeds are moderate in size and not normally dispersed by wind. Management measures including netting when the Camelina is in flower and the use of gas guns and hawk kites will be employed to mitigate the risk of seed removal by birds. Management procedures to minimize the spread of seeds or pollen (such as insect-excluding netting) will further reduce the probability of these events occurring. There will be no compatible species grown for 1000 meters from the boundary of the site and no sexually-compatible wild relatives of *C. sativa* exist in the vicinity of the Rothamsted farm.

The risk of non-sexual, horizontal gene transfer to other species is extremely low. In the event of horizontal gene transfer to bacteria, neither the trait genes nor the marker genes would be expected to confer a selective advantage in the field environment under consideration. We estimate the likelihood of horizontal gene transfer as low and the consequences, were it to occur, as negligible. The area proposed to be planted with GMOs is small and temporary (lasting between 4 and 5 months).

Bearing in mind its limited scope, overall risk of harm to human health or the environmental arising from this trial is assessed as very low.

B7 The methods and plans for monitoring the genetically modified organisms and for responding to an emergency.

The release site will be visited by trained laboratory personnel who are working on the project at no less than weekly intervals (and at some periods, daily) during the growing season of each year of the trial. Any unexpected

occurrences that could potentially result in adverse environmental effects or the possibility of adverse effects on human health will be notified to the Defra immediately. Should the need arise to terminate the release at any point the emergency plans detailed below will be followed.

At the end of each season, the plot will remain in stubble and monitored for volunteers during the remainder of the year and the following season. Any volunteers identified will be destroyed by appropriate herbicide treatment (e.g. glyphosate) or removed by hand and destroyed.

Following completion of the two-year trial the release site will remain fallow for a further season to enable easy identification of volunteers. The site will be inspected regularly and any volunteers identified will be immediately destroyed either by application of a systematic broad leaf herbicide.

Emergency procedures: In the unlikely event that the integrity of the site is seriously compromised, the trial will be terminated and all plants, (including GM and control Camelina plots, and cereal separator) will be destroyed using a suitable herbicide or harvesting as deemed appropriate. All harvested material will be removed from the site and disposed of by incineration or deep burial at a local authority-approved landfill site using an approved contractor. Transportation of waste materials will be in secure containers. The phone numbers of all key staff will be available to site security and farm.
