Q21: Where should the UK be looking for points of comparison overseas? Who are the other international exemplars? What best practice is being modelled overseas that we can learn from?

No response.

Thank you for your time in completing your response to our call for evidence.

Any questions, please get in touch with the Geospatial Commission via geospatialcommission@cabinetoffice.gov.uk

Geospatial Commission: Call For Evidence Response Questionnaire

Please submit your completed questionnaire to:

geospatialcommission@cabinetoffice.gov.uk.

Clearly title your email *'Call for evidence response'*.

About you and your organisation

Name	[Text redacted]
Organisation	Individual response
Job title	[Text redacted]
Address	[Text redacted]
E-mail	[Text redacted]
Telephone	[Text redacted]

Please select which of the following best describes you as a respondent:

Respondent	**Please mark with a X**
Academic	
Business representative / trade body	
Central government	
Charity or social enterprise	
Individual	**x**
Legal representative	
Local government	
Large business (over 250 staff)	
Medium business (50 to 250)	
Small business (10 to 49)	
Micro business (up to 9)	

Other - please state	

Call for evidence - three key themes

We have identified three high-level themes that could help our approach to setting a strategy which are as follows:

1. **Supporting innovation in the geospatial sector**, exploring how to secure cutting edge skills, the right access to data, and opportunities from emerging technologies for the geospatial sector itself
2. **Enhancing the UK's geospatial assets,** looking at how best to align interests, avoid duplication, and instill best practice across the whole public sector
3. **Driving investment and productivity in geospatial applications**, asking in which wider sectors the most value lies from better exploitation and use of geospatial data, in the UK and internationally

Our questions

Q1. Is our view of the geospatial data types accurate? If not, what should be included or excluded from this?

The "geospatial data types" require to be expanded to include:

- Real time aerial photographic digital mapping
- GNSS data sets
- Real time remote sensing data capture – all satellite datasets + radar + Shuttle data + specialist satellites – mineral investigations, oil seeps, etc
- Real time Lidar data
- Environmental monitoring real time satellite data – weather, geotechnical events, vegetation, etc

Nothing should be excluded

Q2. In addition to current government policy, what are the areas of geospatial skills where the commission could best focus, to help ensure the necessary capability within the UK for the future?

Skills in topographic survey, geodesy, computer technology- systems, platforms, databases, etc ; micro-electronics, education at all levels, legal responsibilities about “spatial data” land and hydrographic data collection

Geographical information systems in schools

Support organisations providing new data sets – eg remote sensing –DigitalGlobe, NRSC, SPOT, etc

Q3. What are the geospatial skills needs and gaps in your organisations, how can these be most effectively addressed, and how can careers in the sector be best promoted?

Needs
Better promotion of geomatics, geological, remote sensing and geospatial skills
Further developments in schools and universities for courses
Better remuneration packages

Gaps
Geodetic appreciation of topographic and hydrographic data

Q4. Are there any publicly or privately-held geospatial datasets that are currently challenging to access or use or of insufficient quality, but which you or your organisation would find valuable if these issues could be resolved? Please explain why this would be of value, and how access/quality could be improved?

Private datasets : geophysical and bathymetric datasets of oil & gas basins held in archive by data centres –Norway, Ireland, UK , Hungary Spain etc
Public datasets: The Republic of Ireland has large hydrographic data sets that are difficult to access. These have value in confirming oil and gas datasets.
Faster communication systems are required.
Legal and commercial hurdles require to be addressed.

Q5: Do you anticipate that any changes will be needed to the both address data and the wider address ecosystem, to support emerging technologies? Please provide evidence of value to support any proposed changes.

Faster wireless communication systems are required, faster platforms and bespoke databases.
Real knowledge can be gathered by having a multitude of data sets in the one computer environment.

Q6: How should the commission be looking to develop the UK's capability in Earth observation data, both technologically and to support an effective market?

There needs to be a collaborative approach with all the main data providers: Digitalglobe, SPOT, European and British providers of datasets to a centralised database.

Q7. Which new technologies should the commission focus on to provide new opportunities to process and exploit geospatial data for economic growth?

There needs to be a major research workshop with all interested parties to define the best opportunities:

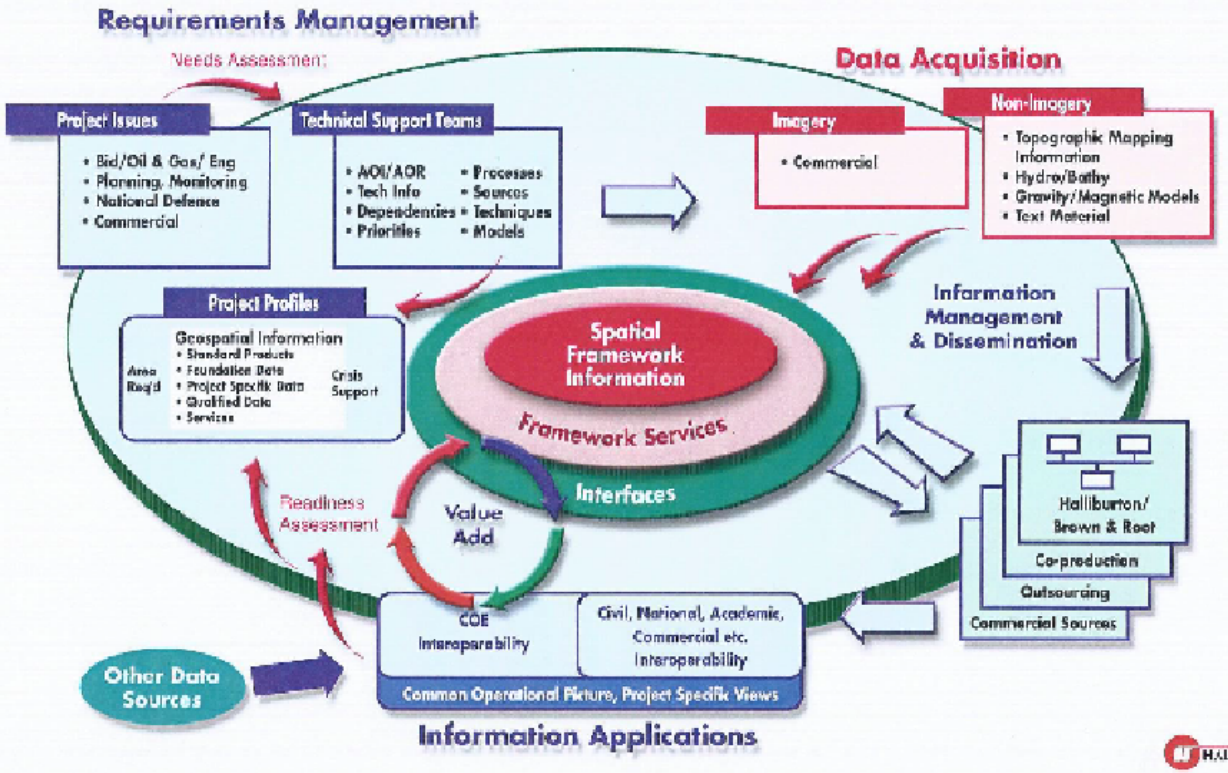
Eg Traffic management – air, sea, railways, roads

Timing mechanisms

Q8. How can geospatial data and applications be used to support enhanced roll-out of future technologies?

See below

Geomatics Process Cycle



Source :NIMA

4575-5

Q9: What are the options for how public sector organisations could continue to invest in maintaining and enhancing our geospatial data assets?

To have a method of recovering costs of data enhancement from other users of the “added value” datasets.

Q10: What areas of the underpinning geospatial infrastructure such as positioning technologies, including GPS and indoor positioning systems, and geodetic networks and frameworks to support them, should we be prioritising the development of, in order to support the emerging requirements for geospatial data?

Join international monitoring GNSS organisations
Generate support aid to countries requiring national digital mapping
Support international mapping organisations
Provide university courses in geomatics, GIS and computer platforms

Q11: What role should the private sector have in both the development and maintenance of the underpinning infrastructure and enhancing the UK’s geospatial data assets?

The private geospatial sector has been decimated in the past thirty years. The next generation requires our support to provide the requisite data at a rewarding cost for its efforts.

Q12. Do you face challenges when working with geospatial data from across the public sector? If so, what are they and how could value be better released? Are there any technical remedies or standards that could be adopted to improve the interoperability of geospatial data? Please provide supporting evidence of what these remedies could help to accomplish.

There are challenges on how the original OS maps were constructed that can lead to inconsistencies.

Is raw GNSS data capture of data points more consistent?

Q13. How can the Geospatial Commission act as a more effective customer for geospatial data on behalf of the public sector?

Becoming a centre of excellence

Q14. Are there any additional geospatial datasets, from the other partner bodies or other sources, that the public sector would derive significant benefit from having access to, that might have novel and valuable use cases? What would that access look like?

Shuttle topographic elevation data for unknown mapped areas

Lidar data for better ground topography –digital ground models.

National archive centres- remote sensing and topographic mapping

Q15: How can we best develop a single UK strategy, ensuring alignment between the individual strategies across the UK while still allwoing for regional variations?

Regular meetings between the interested parties in England, Wales, Scotland and Northern Ireland to determine a coherent way forward.

Q16: How can we best ensure effective local authority coordination and sharing of best practise, using location data to better deliver public services?

Better education and awareness from the national survey authorities in partnership with the best practice operators.

Q17: As a result of this analysis, we are prioritising the exploration of possible initiatives in the high-value categories identified:

- **property and land**
- **infrastructure and construction**
- **mobility**
- **natural resources**
- **sales and marketing**

What are the existing or potential geospatial applications which could be scaled-up or developed in order to capture economic value? (We would particularly welcome responses from industry and other bodies engaged in these sectors.)

GNSS use in engineering and construction for roads, railways and pipelines

Transport management on motorways

Geological and geotechnical investigations/ monitoring of faults, landslips etc

Q18: Are there any other areas that we should look at as a priority?

Generation of databases that can co-exist along side each other trending to a coherent system of data.

Q19: What are the main potential private and public sector innovations that will rely on the use of geospatial data to rollout, and are there corresponding regulatory challenges?

Road and railways planning and construction
New Housing
Planning requirements for councils
Defence usage

Q20: How best can we make the UK's presence in the international geospatial world more visible?

Join international survey and mapping orhanisations – FIG
Equivalent worldwide hydrographic organisations –IMCA, etc

Q21: Where should the UK be looking for points of comparison overseas? Who are the other international exemplars? What best practice is being modelled overseas that we can learn from?

NIMA (USA), IGN (France), Mapping Science Committee (USA), German, Russian (Roskartographia) and Chinese equivalents, Australian, South African and New Zealand equivalents.
Review texts such as :The Future of Spatial Data and Society, Summary of a Workshop produced by National Reseach Council , 1997 ISBN 0-309-05735-3

Q7. Which new technologies should the commission focus on to provide new opportunities to process and exploit geospatial data for economic growth?

Q8. How can geospatial data and applications be used to support enhanced roll-out of future technologies?

Q9: What are the options for how public sector organisations could continue to invest in maintaining and enhancing our geospatial data assets?

Q10: What areas of the underpinning geospatial infrastructure such as positioning technologies, including GPS and indoor positioning systems, and geodetic networks and frameworks to support them, should we be prioritising the development of, in order to support the emerging requirements for geospatial data?

Q11: What role should the private sector have in both the development and maintenance of the underpinning infrastructure and enhancing the UK's geospatial data assets?

Q12. Do you face challenges when working with geospatial data from across the public sector? If so, what are they and how could value be better released? Are there any technical remedies or standards that could be adopted to improve the interoperability of geospatial data? Please provide supporting evidence of what these remedies could help to accomplish.

Q13. How can the Geospatial Commission act as a more effective customer for geospatial data on behalf of the public sector?

Q14. Are there any additional geospatial datasets, from the other partner bodies or other sources, that the public sector would derive significant benefit

from having access to, that might have novel and valuable use cases? What would that access look like?

Q15: How can we best ensure effective local authority coordination and sharing of best practise, using location data to better deliver public services?

Q16: As a result of this analysis, we are prioritising the exploration of possible initiatives in the high-value categories identified:

- **property and land**
- **infrastructure and construction**
- **mobility**
- **natural resources**
- **sales and marketing**

What are the existing or potential geospatial applications which could be scaled-up or developed in order to capture economic value? (We would particularly welcome responses from industry and other bodies engaged in these sectors.)

I refer to the work recently done in Denmark by the Ministry of Taxation and the Danish cadastral organisation to use geospatial data for the purposes of land revalorisation.
I attach a presentation which illustrates how municipal taxation has been overhauled to apply valuation based on geographic non-variables such as plot size, plot location, plot level variance and proximity to amenities (positive such as lakes or negative such as a council rubbish incinerator).

This work enables Denmark to demonstrate compliance with land taxation best practice as defined by the United Nations Economic Commission for Europe:

- Services clearly defined social objectives
- Raises significant revenue
- Exclusive government control
- Administered in a way that the public sees as fair
- Simple and cheap to collect
- Difficult to avoid making payments
- Shares the tax burden equitably
- across the community
- Encourages good use of resources

Property valuation in Denmark .pdf

Q17: Are there any other areas that we should look at as a priority?

Q18: What are the main potential private and public sector innovations that will rely on the use of geospatial data to rollout, and are there corresponding regulatory challenges?

Q19: How best can we make the UK's presence in the international geospatial world more visible?

Q20: Where should the UK be looking for points of comparison overseas? Who are the other international exemplars? What best practice is being modelled overseas that we can learn from?

Call for evidence - three key themes

We have identified three high-level themes that could help our approach to setting a strategy which are as follows:

1. **Supporting innovation in the geospatial sector**, exploring how to secure cutting edge skills, the right access to data, and opportunities from emerging technologies for the geospatial sector itself
2. **Enhancing the UK's geospatial assets,** looking at how best to align interests, avoid duplication, and instill best practice across the whole public sector
3. **Driving investment and productivity in geospatial applications**, asking in which wider sectors the most value lies from better exploitation and use of geospatial data, in the UK and internationally

Our questions

Q1. Is our view of the geospatial data types accurate? If not, what should be included or excluded from this?

Q2. In addition to current government policy, what are the areas of geospatial skills where the commission could best focus, to help ensure the necessary capability within the UK for the future?

It is our opinion that there is a requirement for further collaboration and cross-sharing of skills between domains, of which geospatial skills are one, but data science and computer science should be others. The convergence of these areas will produce innovation – GIScience can progress through coupling with the latest developments in data analytics and technology in general. For example, the areas of artificial intelligence and real time processing are currently at the centre of innovation, and there are a multitude of applications in the GI space.
Similarly it is our opinion that there is a need to introduce awareness of applied geospatial skills in domains that are not always technical by nature – including health, environmental services, utilities and planning. Looking at spatial data through the lenses of a specific domain can unlock new insights that may not necessarily be found by someone with purely geospatial expertise.
In practice, it would therefore be beneficial for the commission to best focus on collaborating with other sectors, in order to introduce GIScience skills into the training and education of professionals in these areas. Similarly, GIScientists should ideally receive a considerable amount of training in programming and general data science in order to further their capability and potential for collaboration with other domains.
We recognise that there is a need across the whole digital and technology industry to close the digital skills gap, and that geospatial skills could also be an aspect of this. Therefore, looking to engage across disciplines rather than silo-ing geospatial skills to geographic training is the way to combat this.

Q3. What are the geospatial skills needs and gaps in your organisations, how can these be most effectively addressed, and how can careers in the sector be best promoted?

Q4. Are there any publicly or privately-held geospatial datasets that are currently challenging to access or use or of insufficient quality, but which you or your organisation would find valuable if these issues could be resolved? Please explain why this would be of value, and how access/quality could be improved?

Q5: Do you anticipate that any changes will be needed to the both address data and the wider address ecosystem, to support emerging technologies? Please provide evidence of value to support any proposed changes.

Q6: How should the commission be looking to develop the UK's capability in Earth observation data, both technologically and to support an effective market?

Q7. Which new technologies should the commission focus on to provide new opportunities to process and exploit geospatial data for economic growth?

It is our opinion that there is a lot of 'untapped' potential in location-enabled smartphones and personal devices in terms of providing locational intelligence. The location-aware capabilities of smartphones are improving rapidly, and their ubiquity can be a great tool to encourage public participation in spatial. Whilst it can be appealing to invest in expensive positioning technologies with high specifications, many common devices are now creating data of a sufficient quality for most purposes. Many other fields are taking advantage of the potential of (automated) data collection from personal devices, and so there are a multitude of ways in which further economic growth can be achieved from the geospatial data already collected. However, with the scale of this data comes the need to invest in technologies to develop the potential for big data and real time processing.
In a similar vein, there would be a lot of value in focusing on the convergence of data coming from the full spectrum of positioning and spatially-enabled technologies – earth observation satellites, high end GPS, smartphones, UAVs, Internet of Things. In particular, gaining rapid access to spatial information to assess a situation, for instance, during natural disasters, could benefit from data pulled from as many sources as possible. Of course, this would need further research into data interoperability between these sources, and perhaps the development of a framework that outlines best practices. Also, this extends the point made in our response to question 2, where we mention how collaboration across sectors is required, to achieve the benefits of the current technology trends in AI and real time processing of data.

Q8. How can geospatial data and applications be used to support enhanced roll-out of future technologies?

Q9: What are the options for how public sector organisations could continue to invest in maintaining and enhancing our geospatial data assets?

Q10: What areas of the underpinning geospatial infrastructure such as positioning technologies, including GPS and indoor positioning systems, and geodetic networks and frameworks to support them, should we be prioritising the development of, in order to support the emerging requirements for geospatial data?

Q11: What role should the private sector have in both the development and maintenance of the underpinning infrastructure and enhancing the UK's geospatial data assets?

The private sector can be considered as large customers of the UK's geospatial data assets, having plenty of experience in using these assets, and therefore have an idea of what works well and what doesn't. They should be able to provide input when decisions are made by the providers of the UK's geospatial data assets on the standards and underpinning infrastructure, e.g. when new version of datasets are released, or assets are migrated to other hosting platforms.
Equally – the potential for the private sector to utilise the UK's geospatial data assets would be increased if their 'user needs' were considered whilst developing the specification of the data standards and ensuring interoperability. Only by considering the requirements of all users (private and public sectors) can we develop data products and platforms that will be beneficial in the long run, and generate opportunities to innovation in the future.
As a D7 country, the UK has a role in pioneering the development of the digital economy, which must include the development of the UK geospatial data assets.

In this spirit of openness and adoption of open standards, we can learn from the work done by the government digital service (GDS) which has paved the way for new interoperable platforms, services, and design practices. All this has been done in collaboration with the private sector, supplying and designing digital services to government – therefore, it cannot be questioned that the private sector have a role to play in continuing this leadership in the digital space.

Q12. Do you face challenges when working with geospatial data from across the public sector? If so, what are they and how could value be better released? Are there any technical remedies or standards that could be adopted to improve the interoperability of geospatial data? Please provide supporting evidence of what these remedies could help to accomplish.

Q13. How can the Geospatial Commission act as a more effective customer for geospatial data on behalf of the public sector?

Q14. Are there any additional geospatial datasets, from the other partner bodies or other sources, that the public sector would derive significant benefit

from having access to, that might have novel and valuable use cases? What would that access look like?

Q15: How can we best develop a single UK strategy, ensuring alignment between the individual strategies across the UK while still allwoing for regional variations?

Q16: How can we best ensure effective local authority coordination and sharing of best practise, using location data to better deliver public services?

Q17: As a result of this analysis, we are prioritising the exploration of possible initiatives in the high-value categories identified:

- **property and land**
- **infrastructure and construction**
- **mobility**
- **natural resources**

- **sales and marketing**

What are the existing or potential geospatial applications which could be scaled-up or developed in order to capture economic value? (We would particularly welcome responses from industry and other bodies engaged in these sectors.)

Q18: Are there any other areas that we should look at as a priority?

Q19: What are the main potential private and public sector innovations that will rely on the use of geospatial data to rollout, and are there corresponding regulatory challenges?

Q20: How best can we make the UK's presence in the international geospatial world more visible?

Q21: Where should the UK be looking for points of comparison overseas? Who are the other international exemplars? What best practice is being modelled overseas that we can learn from?

Thank you for your time in completing your response to our call for evidence.

Call for evidence - three key themes

We have identified three high-level themes that could help our approach to setting a strategy which are as follows:

1. **Supporting innovation in the geospatial sector**, exploring how to secure cutting edge skills, the right access to data, and opportunities from emerging technologies for the geospatial sector itself
2. **Enhancing the UK's geospatial assets,** looking at how best to align interests, avoid duplication, and instill best practice across the whole public sector
3. **Driving investment and productivity in geospatial applications**, asking in which wider sectors the most value lies from better exploitation and use of geospatial data, in the UK and internationally

Our questions

Q1. Is our view of the geospatial data types accurate? If not, what should be included or excluded from this?

Include some reference to points, lines, polygons, raster and vector data. These are the common data types in GIS.

Q2. In addition to current government policy, what are the areas of geospatial skills where the commission could best focus, to help ensure the necessary capability within the UK for the future?

- Geospatial/GIS training could become part of GCSE geography?
- Ensure that government bodies and regulated industries utilise GIS and go digital in their workflows.

Q3. What are the geospatial skills needs and gaps in your organisations, how can these be most effectively addressed, and how can careers in the sector be best promoted?

- Jacobs has a large geospatial team and significant GIS capabilities embedded in parts of other teams. GIS training needs to be cascaded more wider in the other teams.
- GIS could be better covered in undergraduate & postgraduate courses in Civil Engineering/Geology.
- School careers services and STEM activity could promote geospatial careers.

Q4. Are there any publicly or privately-held geospatial datasets that are currently challenging to access or use or of insufficient quality, but which you or your organisation would find valuable if these issues could be resolved? Please explain why this would be of value, and how access/quality could be improved?

- Historical ground investigation (GI) data from government bodies (e.g. Network Rail) & regulated industries (e.g. water, energy).
- This would reduce uncertainty in ground conditions and associated construction delays and overspend.
- Less time would be required digising archive pdf format data.
- Potential for lower spend on future GI work.
- Act of parliament required mandating sharing of GI data with BGS.
- Utility plans often are hard copy or pdf. This causes issues with digitising the locations which is laborious and has potential for inaccuracy with hazardous consequences.

Q5: Do you anticipate that any changes will be needed to the both address data and the wider address ecosystem, to support emerging technologies? Please provide evidence of value to support any proposed changes.

- Post codes may need to be supplemented with Easting and Northing to allow better locational accuracy.
- Data based on postcodes not accurate enough for engineering use e.g. historical petrol tank locations (point data) in Landmark Envirocheck data based on post codes but may be on a large site so not enough accuracy to locate for remediation work.

Q6: How should the commission be looking to develop the UK's capability in Earth observation data, both technologically and to support an effective market?

Commission could fund research or trials of new technology to make UK a world leader in geospatial.

Q7. Which new technologies should the commission focus on to provide new opportunities to process and exploit geospatial data for economic growth?

- Improved public wifi and 5G network.
- Drones and remote sensing.
- 3D printing
- Automation

Q8. How can geospatial data and applications be used to support enhanced roll-out of future technologies?

- Deliveries by drones using Easting & Northings.
- Traffic diversions due to accidents on interactive road signs or via public wifi, similar to live sat nav from Google maps.

Q9: What are the options for how public sector organisations could continue to invest in maintaining and enhancing our geospatial data assets?

Training teams to manage/collate geospatial data where none exist and expanding current resources where they do.

Q10: What areas of the underpinning geospatial infrastructure such as positioning technologies, including GPS and indoor positioning systems, and geodetic networks and frameworks to support them, should we be prioritising the development of, in order to support the emerging requirements for geospatial data?

- Improved public wifi/broadband/5G+ internet connections.
- Improved GPS accuracy, more satellites?

Q11: What role should the private sector have in both the development and maintenance of the underpinning infrastructure and enhancing the UK's geospatial data assets?

- Public utility companies could be regulated to provide their geospatial data to the public as Open Data.
- Telecoms companies own & maintain the infrastructure currently. These are public goods that may be better in public hands.

Q12. Do you face challenges when working with geospatial data from across the public sector? If so, what are they and how could value be better released? Are there any technical remedies or standards that could be adopted to improve the interoperability of geospatial data? Please provide supporting evidence of what these remedies could help to accomplish.

- There are isues with ESRI software and certain WMS datasets being in WGS84 grid vs British National Grid.
- Issues with interoperability between Bentley Microstation, Autodesk C3D, & ESRI ArcMap.
- The loss of EA's "what's in my backyard" website has made it harder for those who are not proficient in ArcMap to view the EA's WMS data.
- Utility plans often are hard copy or pdf. This causes issues with digitising the locations which is laborious and has potential for inaccuracy with hazardous consequences. It would be better if these were available digitally direct from the statutory undertakers as Open Data.

Q13. How can the Geospatial Commission act as a more effective customer for geospatial data on behalf of the public sector?

- Demand that public bodies and regulated industries provide their data digitally as Open Data.
- Set standards for data & data exchange.
- Impose penalties for non compliance.

Q14. Are there any additional geospatial datasets, from the other partner bodies or other sources, that the public sector would derive significant benefit from having access to, that might have novel and valuable use cases? What would that access look like?

- BGS 1:10,000 scale maps are a paid for product that have greater detail than 1:50,000 scale (Open Data). The 1:10,000 scale maps could be added to the BGS geoindex and WMS services.
- Access to statutory undertakers utility plans. These are costly to retrieve and the format is not user friendly. Knowing utility locations and clashes would be a benefit in planning future development.

Q15: How can we best develop a single UK strategy, ensuring alignment between the individual strategies across the UK while still allowing for regional variations?

Set the best standards that the regions will want to adapt.

Q16: How can we best ensure effective local authority coordination and sharing of best practise, using location data to better deliver public services?

Increasing resources of local authority geospatial teams. Imposing geospatial standards on them.

Q17: As a result of this analysis, we are prioritising the exploration of possible initiatives in the high-value categories identified:

- **property and land**
- **infrastructure and construction**

- **mobility**
- **natural resources**
- **sales and marketing**

What are the existing or potential geospatial applications which could be scaled-up or developed in order to capture economic value? (We would particularly welcome responses from industry and other bodies engaged in these sectors.)

- Add 1:10,000 scale geology maps to BGS geoindex and WMS services.
- Health & Safety excutive data should have spatial data captured e.g. where are F10 sites, where are accidents happening, where are fatalities. The data could then be interrogated to improve safety.

Q18: Are there any other areas that we should look at as a priority?

Q19: What are the main potential private and public sector innovations that will rely on the use of geospatial data to rollout, and are there corresponding regulatory challenges?

Drones.

Q20: How best can we make the UK's presence in the international geospatial world more visible?

By promoting our expertise and selling it to the world.

Q21: Where should the UK be looking for points of comparison overseas? Who are the other international exemplars? What best practice is being modelled overseas that we can learn from?

From a geotechnical perspective the UK appears to be ahead of the rest of the world in this field. Particularly the BGS, many developed countries e.g. Germany have no equivalent of the geoindex.

Thank you for your time in completing your response to our call for evidence.

Any questions, please get in touch with the Geospatial Commission via geospatialcommission@cabinetoffice.gov.uk

Geospatial Commission: Call For Evidence Response Questionnaire

Please submit your completed questionnaire to:

geospatialcommission@cabinetoffice.gov.uk.

Central government	
Charity or social enterprise	
Individual	
Legal representative	
Local government	
Large business (over 250 staff)	
Medium business (50 to 250)	
Small business (10 to 49)	
Micro business (up to 9)	

Other - please state	Defra sponsored non-executive NDPB

Call for evidence - three key themes

We have identified three high-level themes that could help our approach to setting a strategy which are as follows:

1. **Supporting innovation in the geospatial sector**, exploring how to secure cutting edge skills, the right access to data, and opportunities from emerging technologies for the geospatial sector itself
2. **Enhancing the UK's geospatial assets,** looking at how best to align interests, avoid duplication, and instill best practice across the whole public sector
3. **Driving investment and productivity in geospatial applications**, asking in which wider sectors the most value lies from better exploitation and use of geospatial data, in the UK and internationally

Our questions

About JNCC

JNCC is the public body that advises the UK Government and devolved administrations on UK-wide and international nature conservation. We make extensive use of geospatial data, to provide evidence based advice on biodiversity and natural capital across the UK, in the Overseas Territories and areas beyond national jurisdiction; examples include species observations, habitat extents, soils and geology, vessel monitoring scheme, earth observation and data on pressures from human activities. JNCC published its Open Data Policy this year and aspires to support and maximise re-use of its data.

Q1. Is our view of the geospatial data types accurate? If not, what should be included or excluded from this?

"

1. Geospatial data: Information where place is a key feature of its source and/or purpose for which it is used.
2. Positional data: Groups of individual datasets that usually have location as a secondary purpose, and which describes activity or physical assets grounded in a particular place.
3. Geospatial identifiers: Data that provides the means of anchoring positional data to core geospatial data.
4. Geospatial services: Higher-level insights and products, often involving layers of various types of spatial information."

The above type definitions seem appropriate for both terrestrial and marine applications.

Q2. In addition to current government policy, what are the areas of geospatial skills where the commission could best focus, to help ensure the necessary capability within the UK for the future?

The availability of locaton based data is improving rapidly, along with sophisticated tools for manipulation and analysis, many of which are free and open source. Geospatial skills and concepts are needed to process, analyse and interpret the data and should be core part of geography, computer science and data science curricula. The skills needed overlap geography, computing, coding and earth observation.

Q3. What are the geospatial skills needs and gaps in your organisations, how can these be most effectively addressed, and how can careers in the sector be best promoted?

JNCC provides evidence products which draw on the increasing volumes of geospatial data available about the environment, including positional data such as vessel monitoring system data, positional data available from social media and the rich geospatial observational data available from Earth Observations. To extract value from these sources requires a combination of geospatial, earth observation and data science and computing skills. Our recruitment shows that there are still relatively few undergraduate or postgraduate training activities that concentrate on providing the combination of skills necessary to handle and extract value from the large volumes of different types of data available. Graduate geographer EO specialists have under-developed scripting and programming skills whereas graduate programmers lack sufficient experience working with location based data and data science skills. The Geospatial Commission can help advocate the need for more multi disciplinary training in higher education to provide the skills needed to exploit the new data sources.

ONS have hosted the 'Data Science Accelerator', backed by GDS and the Government Office for Science. The Geospatial Commission could lead in a similar capacity building 'Geospatial Accelerator' to help leverage benefits from large scale geospatial data.

Q4. Are there any publicly or privately-held geospatial datasets that are currently challenging to access or use or of insufficient quality, but which you or your organisation would find valuable if these issues could be resolved? Please explain why this would be of value, and how access/quality could be improved?

Challenges to data access stem from both licensing and availability and the practicalities of handling and analysing very large volumes of data.

Soils data is currently very costly to access and only available under licence. It would provide a key resource for habitat mapping, habitat condition assessment, natural capital and ecosystem service analyses.

The public sector buys high resolution aerial photography for specific purposes but this is siloed within individual organisations. Common access to aerial photography would be an asset to multiple applications.

There is an explosion in drone use in public and private sector – co-ordinating the archiving and sharing of public sector drone coverage would reduce duplication and maximise re-use / value.

Access to environmental data collected by marine industries (e.g. grab samples, seabed videos) and where not commercially sensitive, acoustic datasets (bathymetry, backscatter, and sidescan primarily). This would be of value because of the sparse nature of marine offshore data, and would fill in gaps with high quality information that can be incorporated into composite products with multiple uses for marine planning, management, monitoring and assessment.

Vessel Monitoring System data can aid estimates of the impact of fishing activity, the major human impact on the marine environment. Access is controlled as it is commercially sensitive but access to aggregated/anonymised data is problematic and data quality is affected by the lack of computing resources available to process it.

Earth observation data (both commercial and open) is increasingly available but barriers to use persist from the data volume and complexity. Specialist knowledge and large-scale computing capacity are required to calibrate and process the raw data into an analysis ready form. Co-ordinated provision of standards based EO data and products would be a significant enabler for public sector and commercial exploitation.

Land parcel boundaries are important data inputs to automated land classification and habitat mapping but examples such as the Rural Land Registry (RPA) are problematic as they are themselves derived from OSMM and habitat classifications derived from the RLR have seen limited distribution.

For data products (as opposed to raw data sets) versioning, update cycle and archiving of previous versions should be a consideration.

There is a requirement for public sector capacity for storage and public distribution of large datasets generated by smaller orgainsations who cannot host the data longterm themselves due to storage and egress costs. The Commission could play a role in providing economies of scale through central hosting and procurement.

Q5: Do you anticipate that any changes will be needed to the both address data and the wider address ecosystem, to support emerging technologies? Please provide evidence of value to support any proposed changes.

Address based geospatial identifiers only have terrestrial relevance and limited value outside populated areas. Terrestrially biodiversity data is captured using British National Grid. Beyond the shoreline latitude/longitude with a defined co-ordinate reference system provides consistent terrestrial and marine coverage.

Q6: How should the commission be looking to develop the UK's capability in Earth observation data, both technologically and to support an effective market?

JNCC has played an important role aiding Defra, Scottish Government, Welsh Government and Northern Ireland assembly in identifying where the recent improvements in Earth Observation Data available under open licenses, most notably Sentinel data from the Copernicus Programme, can help deliver environmental policy. JNCC has provided technical and work programme management to the Defra Earth Observation Centre of Excellence and has contributed to the Scottish Government Remote Sensing Group, Wales strategic evidence EO sub group and supported workshops within NIA.

A key lesson learnt from this work is that many applications share common initial EO processing steps. Where a standard can be agreed for these steps, and data to the common standard shared, there is a dramatic improvement in the productivity of resources used to analyse the data. JNCC has worked with the UK Space Applications Catapult, the National Centre for Earth Observations and others to develop UK Analysis Ready Data standards that align with the global standards work in this area.

Whilst there are benefits to JNCC and other public sector environmental bodies in sharing data sets created to the standards, there will be benefits in some other areas of government, and beyond government to SMEs providing analytical services and to voluntary sector bodies also wishing to use EO data to achieve their charitable objectives.

The Geospatial Commission can help achieve wider participation both in the development and revision of standards, and in creating sustainable mechanisms for generating UK standard data sets and providing access to them, building on the start made through the Defra Earth Observation Centre of Excellence and working with UK Space Agency, NCEO, Space Applications Catapult and AGI.

Q7. Which new technologies should the commission focus on to provide new opportunities to process and exploit geospatial data for economic growth?

As technologies and tools evolve, promotion of open standards for data formats and online services are fundamental to maximising uptake and utilisation of spatial data. The Geospatial Commission should engage with open standards organisations (e.g. OGC) to ensure data and services can be used within both open source and proprietary tools.

Q8. How can geospatial data and applications be used to support enhanced roll-out of future technologies?

No specific response.

Q9: What are the options for how public sector organisations could continue to invest in maintaining and enhancing our geospatial data assets?

The technical expertise and domain knowledge to maintain our geospatial dataset reside in the specialist organisations that originated them. The role of the Commission should be to secure that expertise and provide the impetus and infrastructure to make the data as openly available as possible.

Q10: What areas of the underpinning geospatial infrastructure such as positioning technologies, including GPS and indoor positioning systems, and geodetic networks and frameworks to support them, should we be prioritising the development of, in order to support the emerging requirements for geospatial data?

No specific response.

Q11: What role should the private sector have in both the development and maintenance of the underpinning infrastructure and enhancing the UK's geospatial data assets?

The role of the private sector in development and maintenance of inftrastructure is welcome as long as it is predicated on the provision of open standards based data formats and services.

Key data assets should be produced for the public good (OS mapping, soils, geology, habitat mapping, crop mapping, flood risk, aerial imagery, LiDAR, EO ARD). These should be made openly available to enable private sector to innovate in producing new value added products and services.

Q12. Do you face challenges when working with geospatial data from across the public sector? If so, what are they and how could value be better released? Are there any technical remedies or standards that could be adopted to improve the interoperability of geospatial data? Please provide supporting evidence of what these remedies could help to accomplish.

Some public sector datasets have significant value beyond the originating organisation but the originators lack financial or technical resources to effectively manage access (taking into account the work to remove personal information or commercially sensitive detail). VMS data is an example of 'big data' that requires significant processing at scale but due to the large data volumes is currently reliant on subsampling to make the data processing manageable. The remedy is to provide technical/financial resources to unlock their value to others.

JNCC are a member of the PSMA and its successor giving enhanced access to OSMM. Challenges remain in creating usable datasets from it e.g. generating a continous coastline layer for defining coastal extents of protected areas is very time consuming. A library of routinely updated, widely applicable standard products would be highly valuable if they could be used freely without the restrictions of 'derived data'.

JNCC is heavily dependent on partnership agreements and citizen science groups for collection of much our terrestrial data. These bodies don't have easy access to detailed mapping (including land use and ownership) for access and data capture. More open access to this data would improve the quality of collected data.

Q13. How can the Geospatial Commission act as a more effective customer for geospatial data on behalf of the public sector?

The commercial Earth Observation sector is providing an increasing range of observing products, varying from very high resolution, low frequency, high cost but very information rich observations, to daily coverage with lower resolutions and less information collected. JNCC has experience in combining both commercial and open EO data to provide effective environmental evidence and sees an increasing role for commercial data, if its purchasing can be streamlined and the costs and licensing negotiated so that it is within reach of operational public sector budgets. At present the UK Space Agency, through its Space for Smarter Government Programme, is working with public bodies to develop understanding and test use cases for applying commercial EO data sources, but it does not have the remit or function to create the cost effective purchasing mechanisms and licensing, such as exists for aerial photography. Modern collective purchasing agreements also need to look at where they can reduce costs in using the data, through the provision of OGC services, and placing the data sets where they can be used analytically together. The Geospatial commission can help by either creating frameworks for dispersed purchasing of new data sources such as EO or by pulling together the requirements and business cases for collective purchasing.

Q14. Are there any additional geospatial datasets, from the other partner bodies or other sources, that the public sector would derive significant benefit from having access to, that might have novel and valuable use cases? What would that access look like?

Assessing the UK's marine natural capital assets would benefit from open access to the highest quality bathymetric products, and open access to data collected from seabed samples by BGS.

Monitoring and assessing habitat condition would be improved with easy, timely and free access to comprehensive data from Vessel Monitoring Systems (VMS) including increasing the volume of data processed by making additional processing power available.

Q15: How can we best develop a single UK strategy, ensuring alignment between the individual strategies across the UK while still allwoing for regional variations?

The Geospatial Commission should provide clarity over is role and relations with the four countries. Its partner organisatons have a variable footprint with limited coverage in Scotland and particularly Northern Ireland where only UKHO have a remit.

Q16: How can we best ensure effective local authority coordination and sharing of best practise, using location data to better deliver public services?

No specific response.

Q17: As a result of this analysis, we are prioritising the exploration of possible initiatives in the high-value categories identified:

- **property and land**
- **infrastructure and construction**
- **mobility**
- **natural resources**
- **sales and marketing**

What are the existing or potential geospatial applications which could be scaled-up or developed in order to capture economic value? (We would particularly welcome responses from industry and other bodies engaged in these sectors.)

No specific response.

Q18: Are there any other areas that we should look at as a priority?

No specific response.

Q19: What are the main potential private and public sector innovations that will rely on the use of geospatial data to rollout, and are there corresponding regulatory challenges?

No specific response.

Q20: How best can we make the UK's presence in the international geospatial world more visible?

No specific response.

Q21: Where should the UK be looking for points of comparison overseas? Who are the other international exemplars? What best practice is being modelled overseas that we can learn from?

The Copernicus Programme have a free and open data access policy for earth observations data to encourage maximum use by small companies and public sector alike.

EMODnet (European Marine Observation and Data Network) www.emodnet.eu - a network of organisations working together to collect, process and make freely available data from the marine environment, as interoperable data layers and data products. Themes covered: Bathymetry, Geology, Seabed Habitats, Chemistry, Biology, Physics and Human Activities. The target audiences are public sector, civil society, private sector and the research community.

Thank you for your time in completing your response to our call for evidence.

Call for evidence - three key themes

We have identified three high-level themes that could help our approach to setting a strategy which are as follows:

1. **Supporting innovation in the geospatial sector**, exploring how to secure cutting edge skills, the right access to data, and opportunities from emerging technologies for the geospatial sector itself
2. **Enhancing the UK's geospatial assets,** looking at how best to align interests, avoid duplication, and instill best practice across the whole public sector
3. **Driving investment and productivity in geospatial applications**, asking in which wider sectors the most value lies from better exploitation and use of geospatial data, in the UK and internationally

Our questions

Q1. Is our view of the geospatial data types accurate? If not, what should be included or excluded from this?

Definitions 2. and 3. in the call for evidence are sound.

Definition 1. as written may inadvertently limit understanding of the ubiquity of geospatial data.

For example, within the HR database for a large employer, the geographic identifier may not generally be understood as being a **key feature** of either the source or purpose of the database. Nonetheless, within our consultancy practice, the use of client HR databases in GIS has proven invaluable in quantifying how changes to that organisation's property portfolio can impact staff commuting time, enabling better decision making.

Accordingly our recommendation is that the word "key" is dropped, and "or could be used" is appended:

- Any information where place is a feature of its source and/or the purpose for which it is used or could be used.

Definition 4. as written might suggest that only higher level analyses, based only on discrete data inventories, constitute services driving understanding and value from geospatial data.

For example, in our consultancy practice higher-level geospatial output would be a macroeconomic summary like "what homeowners intend to do in the next 5 years, by local authority area", whereas a conceptually basic GIS finding would be "3 of 10 of this developer's candidate sites are bisected by high voltage cables." The

former might be a press piece and the latter might be specific advice to a client, but the latter is clearly crucial information when applied in context.

This highlights the subjectivity of the term “high-level” when defining geospatial services; we would recommend this is not used.

In addition, a definition based around the concept of layers implies the benefit is mainly derived from analysis of discrete data inventories, when information synthesis and further statistical assessment through GIS are equally powerful facets of the technology.

Accordingly we would suggest the explicit reference to layers is dropped.

A possible alternative could be:

- Insights and products, usually articulating spatial characteristics or relationships

Both suggestions above are aimed at promoting the broadest possible recognition of the potential to harness geospatial data.

Q2. In addition to current government policy, what are the areas of geospatial skills where the commission could best focus, to help ensure the necessary capability within the UK for the future?

Three priority skills areas that could be examined to bolster UK geospatial capability are:

1) Programming/Scripting
2) Data Management
3) Professional Impact

Programming & Scripting

The former would help address the skills gap in the technology sector already recognised by coding lessons being provided in schools.

(Related to Q3, how can careers in the sector be best promoted?)
A possibility would be for the Geospatial Commission to look to encourage collaboration between GIS modules taught in Geography and any coding curriculum. Examples include SQL and Python. Whilst programming/scripting is not necessary for a successful career in GIS it does provide more flexibility and opens up career opportunities, particularly as a developer. The job security, flexibility and greater salary offered by having programming skills should encourage careers in the sector.

Data management

GIS skills can sometimes become associated with specific software platforms, whereas the prerequisite bulk data management skills may encompass a number of systems, both spatial and non-spatial. The ability to handle and manipulate large volumes of data should be seen as fundamental to delivering value from geospatial data use.

This skill would be taken for granted across other technical specialisms, such as data warehousing. The disparity could be for a number of reasons e.g. time required to train a user on the GIS element alone, a focus on short-term GIS projects, or *task* as opposed to *outcome* focused work.

A data management skills focus also supports interoperability with BIM development and would facilitate better flow of geospatial data. It should not be the case, for example, that the first time geospatial practitioners and architects try to make sense of each other's digital worlds is out in industry; asset-sharing and joint problem solving needs to be taking place between courses and faculties within universities.

The crossover with BIM improves salary expectations which should make the Geospatial Industry more attractive. Crossover with BIM and related industries will improve job security. Whilst there are plenty of free, online courses these skills gaps could be formally addressed through courses at "Centres of Excellence" proposed by the Geospatial Commission. In addition, industry wide standards for GIS specific / general data management could be created as per BIM PAS 1192 http://bim-level2.org/en/standards/. If these standards are seen as attractive to clients in a similar manner to professional accreditations (e.g. CGeog) then data management practices will be raised across the industry.

Professional Impact

Geospatial practitioners struggle to exert a coherent collective identity, and we have observed this manifesting itself in third party organisations as geospatial capability being overlooked, misunderstood, poorly tasked, wrongly considered as an IT issue, or judged solely on its revenue generating merits.

We have observed procurement decisions made by parts of the public sector that displace and marginalise in-house geospatial capability. We have observed cases where, on our recommendation, public sector organisations have sought to increase their capability but funding is denied, only for greater sums to be spent on consultants offering similar or reduced capability. We have seen representatives from public bodies publicly endorse third party products but privately concede they know such procurement involves overcoming significant interoperability challenges that have been flagged by their in-house geospatial practitioners.

These are confidence issues that must be addressed; confidence from the individual practitioners themselves, and confidence within the organisations as a whole to

deploy skilled people and technology where they can be best utilised.

For individuals, collaboration and collective problem-solving skills must be more of a focus during university. Students of geospatial science must be linked up with courses that address in-depth the pressing needs of society, and they should be encouraged to see past the initial and more superficial stages of analysis and data reconciliation to take ownership of the subject matter.

Too many candidates that we have interviewed have jumped from one GIS role to another, bouncing between industries demonstrating knowledge and experience of the systems and methods, but little commitment to (or passion for) the subject matter. If they fail to fully understand and engage with the subject matter of the organisation their capability supports, they will have limited success in owning and disseminating actionable insight from that capability.

The reach of the Royal Geographical Society's Chartered Geographer programme should be expanded, as it represents a mechanism by which geographers out in industry remain connected and engaged with peers, and potentially, trained. The Commission should take a position on whether some of the skills gaps identified are translated to accreditation requirements.

Similarly, the Royal Institution of Chartered Surveyors has the accreditation competency "property records and information systems". [Text redacted]

Both accreditations should be adapted to encourage more intra-disciplinary skill transfer, for example by setting minimum number of hours CDP across major heading such as technical skill, communications, formal training etc.

Any broader changes to the curriculum needed to address the above deficiencies should clearly be differentiated by level, but there should be a gradual and continuous increase in the understanding of geography and geographic data using everyday examples like smartphones and apps.

Even at higher levels of education, a greater awareness of the value of geospatial data exploration and insight in non-GIS courses is highly recommended; this would promote a better common understanding of the value of geographic data.

Q3. What are the geospatial skills needs and gaps in your organisations, how can these be most effectively addressed, and how can careers in the sector be best promoted?

Skills and careers for industry more broadly are covered in question 2.

Geospatial needs gaps at Knight Frank mainly relate to public sector data use.

[Text redacted]

In addition to policy layers, we also require planning applications data, including the digital red-line extent and any associated massing data (such as a BIM model or its 3D shell) submitted to a local authority. See question 4 for commentary on public sector data availability.

Q4. Are there any publicly or privately-held geospatial datasets that are currently challenging to access or use or of insufficient quality, but which you or your organisation would find valuable if these issues could be resolved? Please explain why this would be of value, and how access/quality could be improved?

Geospatial data is key national infrastructure, but has not been clearly identified as such across government.

The National Infrastructure Assessment covers the importance of a fully digital economy but does not mention National Spatial Data Infrastructure; for which obligations were transposed into UK law in 2009 through the EU INSPIRE Directive. References to BIM, GIS and geospatial data are also absent in any explicit form.

The National Planning Policy Framework draws no attention to geospatial data as an asset of the public sector in opportunity appraisal, the creation and standardisation of evidence, or plan-making.

Physical Infrastructure Data

One example of how these incongruities manifest themselves is the proposed Oxford-Cambridge Expressway, key physical infrastructure for which £27 million has already been committed. In our most recent request to Highways England for geospatial route options data, we were instead referred to a .pdf which a team member was then required to georeference and digitise.

In the property industry we need to rapidly make sense of new infrastructure proposals and their likely effect on client portfolios, the housing market and the wider socio-economic landscape yet we are interpreting, re-creating and indexing spatial data originating from the public sector.

Knight Frank has the resource to recreate this data but others do not. While the Berks, Bucks & Oxon Wildlife Trust brought environmental concerns about the

Expressway to light in a BBC report in May of this year, their website shows that as of September they are still waiting for detailed GIS data from Highways England to fully assess the impact.

In this instance, the cumulative effect of the obfuscation and lack of timely cross-examination has been characterised as a "democratic malaise", with a particularly serious charge against "megalomaniacs who draw lines on maps" appearing in the Guardian in August.

As an example it shows how GIS data is at once central to, and yet absent from, discussion on sustainable growth and the changing socio-economic landscape.

Part of the Commission's role should be to fully realise the concept of the "Digital Twin" as set out in the National Infrastructure Assessment and mould it around data defining function, form and location. In this case the definition must be sufficiently specific so as to include detailed, accurate and attributed GIS data, released to estate agents and wildlife trusts alike, at the point at which route options are announced.

It is also important that, post-Brexit, the Commission considers in what form the INSPIRE directive will be retained in domestic law.

Policy & Future Land Use Allocations

The Commission's Partner Bodies comprise a spread of organisations focused on physical and cadastral topography; a "what is" view of the UK. One of its early challenges will be to build stronger links with organisations with plan-making powers to flesh out the "what next" view.

There are troves of spatial data on future land allocations spread across the public sector which are urgently needed by industry.

In a portfolio review Knight Frank conducted for [Text redacted], we profiled all industrial land in London and cross-referenced this with London Plan allocations on Strategic Industrial Land (SIL) so [Text redacted] knew which sites could be considered for use in perpetuity. However the Greater London Authority (GLA) could not provide us with a GIS file defining the outlines of London's protected industrial sites, stating the data was a borough resource and was only available through the individual local authorities. None of the authorities in question provided readily available GIS data, and again Knight Frank were again left to examine .pdf documents of varying scales and standards. The quality of advice that Knight Frank was able to offer [Text redacted] was affected by the lack of availability of this strategic geospatial data.

In this case the lack of centralisation of SIL data was particularly surprising given the GLA's role in ensuring SIL consistency with cross-boundary OAPFs (London Plan Policy E5 B3. 3). The procedure for SIL release also heavily involves the GLA,

whose oversight is required in ensuring a London-wide balance between housing and industrial land use (London Plan Policy E5 D.). SIL is essentially a GLA policy mechanism disavowed as a borough data asset.

The GLA included a map of SIL across Greater London in the London Plan, but it was the output of a graphic designer. We would strongly recommend that plan-making bodies are made responsible for the collation and centralisation of strategic land allocation data. [Text redacted].

There are clear precedents for doing this, for example the Town Centres hierarchy in fulfilment of EU Commission / Eurostat Urban Audit requirements. The resulting single London-wide town centres layer has existed in a consolidated form as part of the London Datastore from at least 2008.

Again, like the INSPIRE directive, the implication is that the public sector is willing and capable of compiling and publishing strategic geospatial data where there is an explicit legal duty to do so. While this suggests some changes might only be achieved through legislation, these changes would be low cost and high gain.

Planning policy allocations are deliberated on through a diligent and fastidious process at great expense to the public sector. However, the culmination of these efforts - the adoption of a local plan - is not accompanied by a corresponding release of spatial data guiding the efforts of land agents and developers in realising the vision articulated by the local authority. This is a missed economic opportunity and should be a matter of considerable focus for the Commission.

Changes to Existing Dissemination Mechanisms

The above examples illustrate cases where organisational and operational changes are needed before access mechanisms need to be considered. However there are a significant number of public sector organisations that have already made great strides towards opening up geospatial data.

Two examples of note are the Coal Authority and the London Borough of Tower Hamlets. Both have substantial spatial data resources and have built web systems where the data can be accessed as a WMS.

The Coal Authority, however, has introduced a scale threshold on its WMS feed, meaning the data feed cuts out below 1:25,000. This is assumed to be to protect the organisation against the use or interpretation of data at larger scales, when it was never intended to be so accurate. However, the by-product of this is that it is not possible to send a spatial relationship query to this WMS feed. For a development portfolio of 1000 sites, we cannot tell a developer how many might be affected by historic coal-mining. In building complex site appraisal models that run as scripts and report on multiple criteria, we are forced to omit any layers that cannot be queried in GIS.

It raises the question of why the Coal Authority, in building such capability, has not passed on detailed caveats to industry about how the data was created, and why it is subject to interpretation or caveats beyond certain scales, instead of simply denying end-users the ability to query it.

It is certainly possible to manage such data responsibly. In dealing with [Text redacted] Council, we previously took local plan data themes as raw data, even though [Text redacted] Council advised us that the boundaries had only been created for use at 1:10,000. We were able to use them at larger scales but with appropriate checks and techniques to manage and caveat findings accordingly.

Similar to the Coal Authority, the London Borough of Tower Hamlets provides local plan policy data as a WMS feed, in what could certainly be seen as a standard for discussion with the Local Government Association. Consumers of this WMS feed can view the data at any scale, but again are denied download and query capability on this data.

These organisations have already taken considerable initiative in organising spatial data and systems that communicate opportunities and constraints to the property sector. They simply need better direction on how to embed scale and usage caveats into metadata so that information can be opened up in its more useable form.

Q5: Do you anticipate that any changes will be needed to the both address data and the wider address ecosystem, to support emerging technologies? Please provide evidence of value to support any proposed changes.

For Knight Frank, the ability to establish links from address data across other government point and polygon data is key, and we are largely able to achieve this using Ordnance Survey AddressBase.

Limitations of this database are exposed for apartment buildings, where multiple address points will appear on the same building centroid. These points are also not differentiated by floor.

This causes issues during [Text redacted] assessment, where a building might contain 20 addresses, 5 of which have been classified as commercial and the remainder residential. It is not possible to estimate the volume or percentage of commercial use within that building using the floorplate in OS MasterMap because a database user cannot tell if a commercial unit is ground floor only or is occupying multiple floors. If it was known that residential addressing began at floor 3 for example, then an accurate determination of the retail component could be made. Additionally, if all residential addresses contained a link to floor number, much better density figures and ceiling height estimates could be determined. A conceivable mechanism for gathering this information would be through the voter registration teams in individual local authorities.

Addressing using gazetteer products such as Ordnance Survey AddressBase suffers from the lack of general visibility of the UPRN unique identifier in the data. In attempting to propagate the use of the UPRN, Ordnance Survey licencing permits subscribers who have fallen out-of-licence to retain it against any proprietary address data, in theory allowing further cross-referencing.

However, to the general public or for organisations along a physical supply chain, the UPRN remains highly abstract and is not used. The postcode remains the go-to address identifier but in its current form cannot function as a UPRN.

In addition to better differentiated 3D addressing, future developments must include the convergence of the concept and use of the UPRN with the ubiquity of the postcode. The Irish system incorporates a postcode that is unique to the individual property, ostensibly to facilitate more reliable deliveries and routing, and should be evaluated technically.

Q6: How should the commission be looking to develop the UK's capability in Earth observation data, both technologically and to support an effective market?

The frequency of provision of earth observation data, and its granularity, has significant potential to drive benefit. Pixel recognition technology means that changes in land use could be detected much closer to real-time, for example monitoring where there is a cumulative risk to urban habitats, biodiversity, or surface water run-off from households paving over gardens.

Thermal insulation imaging has the potential for significant economic benefit in reduced fuel bills, but this also requires highly granular infrared imagery captured more regularly.

Q7. Which new technologies should the commission focus on to provide new opportunities to process and exploit geospatial data for economic growth?

New technologies that would support the property industry would include mechanisms for better provision of station-to-station travel data through TfL and other transport providers, movement sensors routinely monitoring and democratising footfall figures, and AI feature classification tools for both aerial and street level (i.e. Google StreetView) imagery.

Technology or methodologies accurately determining (or cross-referencing) building stock age would be hugely beneficial within property and planning.

Q8. How can geospatial data and applications be used to support enhanced roll-out of future technologies?

/

Q9: What are the options for how public sector organisations could continue to invest in maintaining and enhancing our geospatial data assets?

As touched on under Question 2, this is largely a function of the confidence and profile of individual geospatial practitioners, the technical understanding and leadership of those above them, and the level of integration of procurement practices across that organisation.

A significant risk to the relevance of the geospatial industry in the UK is the excruciatingly slow move to 3D across the public sector. As referenced, we have observed cases where public sector GIS teams were denied funding to embed 3D capability, only for greater sums to be spent on external consultants offering 3D in platforms that are not interoperable with GIS.

We know of one external consultant excluding potential customers' in-house GIS teams from discussions on systems and standardisation to end-run interoperability concerns. The end result is that the local authorities who procure this system:

- Cannot create and visualise their own massing models in a 3D environment
- Cannot cross-reference insight derived from these 3D models with the vast catalogues of spatial data held within that local authority
- Must continue to engage the external consultant in question to add new 3D massing and development proposal models into the visualisation system (this increasingly complete future skyline model is then used to sell the capability into other local authorities.)

The local authorities in question never own and can never democratise the component data. Despite furnishing the third party provider with detailed planning applications and proposals data, their only tangible return is a rolling year-on-year subscription to the software.

New procurement mechanisms for systems handling spatial data are urgently required across the public sector in order to protect years of investment in systems and skill that have delivered considerable gains for industry. This would also protect the ability of these authorities to work collaboratively with a range of stakeholders across industry.

This mechanism might include a mandatory evaluation question such as “Does the proposed external capability analyse or visualise geospatial data?”, in which case the affirmative would require the sign-off of the Head of IT to ensure obvious opportunities to bolster in-house capability are not missed.

Q10: What areas of the underpinning geospatial infrastructure such as positioning technologies, including GPS and indoor positioning systems, and geodetic networks and frameworks to support them, should we be prioritising the development of, in order to support the emerging requirements for geospatial data?

The evidence base for larger mixed use development proposals will almost always include estimates of footfall and movement data, and indeed there are consultants who specialise in either modelling this data (spatial attraction models) or providing actual counts based on aggregated mobile phone data.

The problem here is that the modelled data can be subjective, while mobile phone data is incredibly expensive to deploy. There is a danger that this important aspect of urban planning is not evidenced in any universally queryable way.

Going forward, essential infrastructure must include footfall sensors routinely monitoring and democratising movement data. This could unlock benefits from urban grain permeability assessment to determining optimum planning use mix in revitalised high streets.

Q11: What role should the private sector have in both the development and maintenance of the underpinning infrastructure and enhancing the UK’s geospatial data assets?

We believe that the private sector should have a leading role in the development of the UK's geospatial capability. The private sector must be able to provide pertinent insight and expertise to Government on the use of geospatial data in addressing pressing questions of industry, removing uncertainty, and driving growth.

Rather than just initial input, this would be an ongoing consultation where the private sector is used to identify new datasets and enhancements and giving a sense of how the data will be utilised outside of the public realm.

Conceivably, additional private sector reporting responsibilities could drive the identification of new opportunities. For example, [Text redacted]

More broadly, it is the role of firms like Knight Frank to enable data-driven decisions and develop analytic insights, partnerships, and products for clients. These partnerships develop and endure over a number of years, and only through this long-term collaboration do we get the full sense of the client's operational and land requirements, which in turn informs our understanding of industry spatial data needs.

We do have a concern that there is an implicit focus on SMEs and start-up enterprises as the primary means of driving innovation and creating new opportunities from within the geospatial industry.

Unlike the National Infrastructure Assessment and National Planning Policy Framework examples in Question 2, the National Industrial Strategy White Paper singles out the potential of the UK's world class geospatial data.

It states the following government policies:

- "We are committed to making this data available to innovators"
- "We want the UK to be the best place to start and run a digital business."
- "We will explore means of identifying businesses with scale up potential"
- "We will […] open up freely OS MasterMap data to UK-based small businesses in particular"

There is an implicit conceptual link here between innovation and SMEs, and while clearly there are many examples supporting such a premise, Government cannot afford to miss the enormous economic potential of working with larger and more established businesses.

Engagement beyond the Call for Evidence and subsequent strategy must reflect the data needs of larger established players, where there is:

- Broad existing client base and potential reach, with a proven ability to match land acquisition and development opportunities with client financial and operational models

- Substantial existing investment in technology, infrastructure and analytical capability
- Specialists who interpret findings for specific geographic and thematic submarkets
- A greater willingness to be transparent about methodology and interoperability (assumed to be because it is taking similarly sized competitors longer to recreate comparable bespoke geospatial research)

By approaching each client problem differently, we spot similarities and differences between submarket data requirements that bolster our understanding of needs of industry more broadly.

Our recent industry accolades include the 2018 Innovation Award from the British Property Federation, where there were several start-ups in our category. We would ask that the Commission accordingly recognises the key role of larger established business in driving innovation and new value for industry using geospatial data.

Q12. Do you face challenges when working with geospatial data from across the public sector? If so, what are they and how could value be better released? Are there any technical remedies or standards that could be adopted to improve the interoperability of geospatial data? Please provide supporting evidence of what these remedies could help to accomplish.

See question 4.

Q13. How can the Geospatial Commission act as a more effective customer for geospatial data on behalf of the public sector?

The Commission needs be very visibly seen to act for both geospatial capability as a technical and analytical disciple, and, as explained in a number of examples above, for the profession and its practitioners.

Q14. Are there any additional geospatial datasets, from the other partner bodies or other sources, that the public sector would derive significant benefit from having access to, that might have novel and valuable use cases? What would that access look like?

A thorough understanding of business and employee numbers and composition within custom geographic areas is currently lacking within property, planning and development.

The ONS inter-departmental business register (IDBR) has enormous untapped potential in this regard, but is subject to stringent controls and is typically only used within local authorities. The rationale is that the data is disclosive, but that is to ignore the possibility that minimum thresholds could be set on the number of records used to compile a response via a WMS analysis server.

For example, we would like to be able to say "what is the % of the workforce employed in manufacturing within a 15 minute drive of Oxford". The result to this query would not be disclosive, if the ONS provided an analysis server that could accept the incoming 15 minute isochrone polygon and query it against raw data. The data could be checked before it leaves the ONS server to verify that it describes either a minimum number of businesses or a minimum number of employees.

Additionally, there is insufficient data available to us to advise developer clients on subsurface hazards, and part of the Commission's work could be to flesh out or co-ordinate minimum standards and access requirements for such information. We have been asked by clients for contextual geospatial data on electricity, gas and sewerage systems as well as unstable bedrock / sinkhole risks and areas potentially still at risk through historic mining.

Q15: How can we best develop a single UK strategy, ensuring alignment between the individual strategies across the UK while still allwoing for regional variations?

Scotland and Northern Ireland have become "terra incognito" for developer site and opportunity finding using digital cadastral data in GIS. Both administrations should be encouraged to greatly accelerate efforts to devolve cadastral data, even with minimal attribution, to enable site searches to take place.

Knight Frank advises clients with large national portfolios, such as [Text redacted], but much of our insight is limited to England and Wales because we lack the ability to readily tie ownership extents to other data sources for Scotland and Northern Ireland.

Q16: How can we best ensure effective local authority coordination and sharing of best practise, using location data to better deliver public services?

The Commission is advised to snapshot local authority capability nationally through the Local Government Association.

This “census” should be addressed to Chief Executives, and should be seen as an opportunity to:

- Restate broadly that geospatial information should be seen as national infrastructure and that local authorities have a special responsibility for protecting and resourcing this asset accordingly
- Determine the number of people in that authority who are geospatial practitioners, GIS operators, gazetteer custodians or geographers (relative to the size of the local authority’s staff base and its area population)
- Capture current job titles, number of years experience, and levels of seniority
- Capture any impediments to the widespread deployment of the technology or the further upskilling of staff
- Aim to determine why there is such divergence in approach between individual local authorities e.g. local plans published to a variety of technical standards and scales
- Capture key successes for benchmarking

Q17: As a result of this analysis, we are prioritising the exploration of possible initiatives in the high-value categories identified:

- **property and land**
- **infrastructure and construction**
- **mobility**
- **natural resources**
- **sales and marketing**

What are the existing or potential geospatial applications which could be scaled-up or developed in order to capture economic value? (We would particularly welcome responses from industry and other bodies engaged in these sectors.)

IDOX must be incentivised to pool and democratise geospatial data relating to planning applications for the c. 200 local authorities it provides planning portals for. This single joined up picture of planning applications, including those rejected and lapsed, and the exact spatial extents they relate to, have been described as “vital” information by a number of our developer clients.

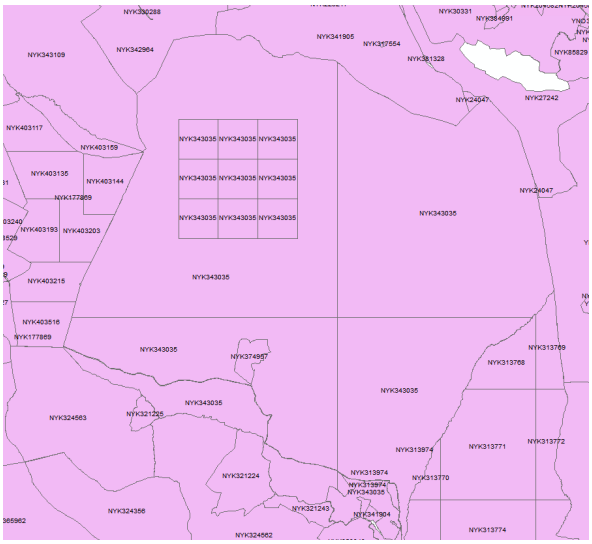
Q18: Are there any other areas that we should look at as a priority?

Ownership of data themes: a number of local authorities have dismissed data access requests on the sometimes opaque grounds of “data ownership” – usually on the basis that a data subcomponent, or some element of the base data, has come from another entity (even when any objective bystander would associate the synthesized or completed data solely with the body we have requested it from).

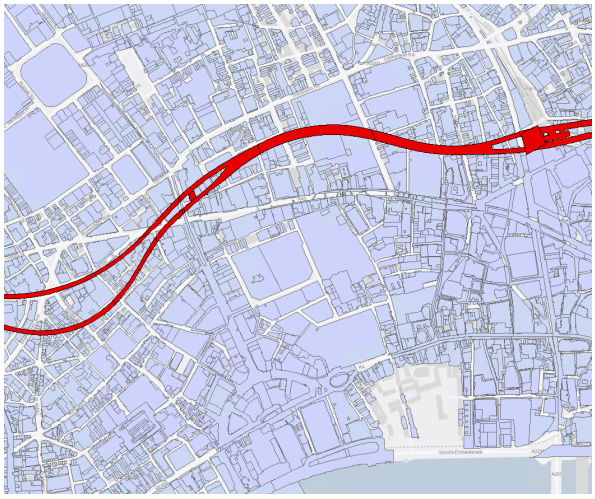
There needs to be clearer distinction between different tiers and hierarchies within public planning as to what data can and can’t be shared, given we have seen differing approaches across a number of authorities.

Another issue that needs to be addressed as a priority is the structure of the Land Registry National Polygon Dataset

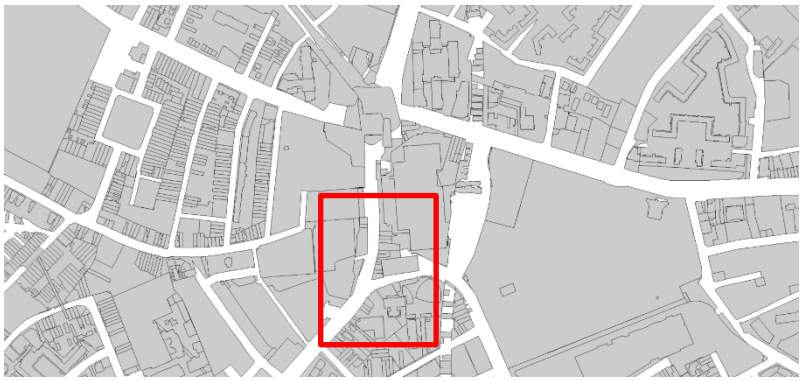
Large titles sometimes show as a grid. This is problematic when joining datasets and calculating area or extent of ownership:

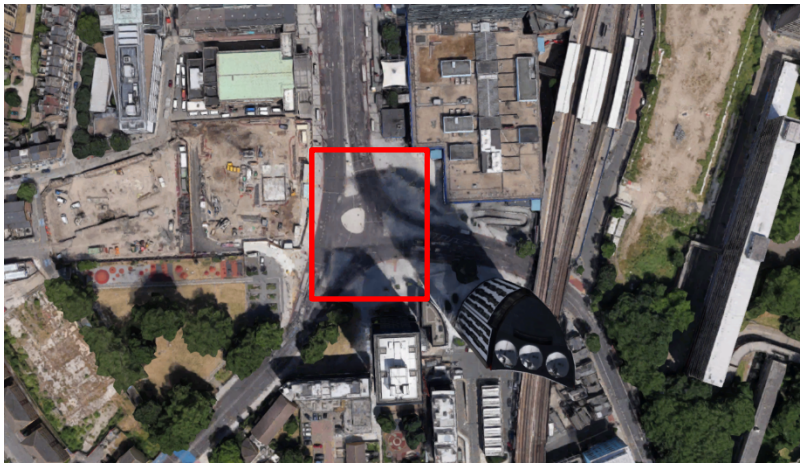


Subterranean parcels are visible but without an identifying attribute to suggest they are subterranean. It would be useful to have an attribute to identify these to filter titles:



Historic parcels have not been removed following redevelopment:





Q19: What are the main potential private and public sector innovations that will rely on the use of geospatial data to rollout, and are there corresponding regulatory challenges?

/

Q20: How best can we make the UK's presence in the international geospatial world more visible?

Co-ordination and engagement with bodies such as FIG (International Federation of Surveyors) and other international agencies with strong links to the UK geospatial community (MapAction, MSF etc.)

Q21: Where should the UK be looking for points of comparison overseas? Who are the other international exemplars? What best practice is being modelled overseas that we can learn from?

Centralised 3D planning and massing models:

Geospatial Commission: Call For Evidence Response Questionnaire

Please submit your completed questionnaire to:

geospatialcommission@cabinetoffice.gov.uk.

Clearly title your email *'Call for evidence response'*.

About you and your organisation

Name	[Text redacted]
Organisation	Lancaster City Council
Job title	[Text redacted]
Address	[Text redacted]
E-mail	[Text redacted]
Telephone	[Text redacted]

Please select which of the following best describes you as a respondent:

Respondent	**Please mark with a X**
Academic	
Business representative / trade body	
Central government	
Charity or social enterprise	
Individual	
Legal representative	
Local government	**X**
Large business (over 250 staff)	
Medium business (50 to 250)	
Small business (10 to 49)	
Micro business (up to 9)	

Other - please state	

Call for evidence - three key themes

We have identified three high-level themes that could help our approach to setting a strategy which are as follows:

1. **Supporting innovation in the geospatial sector**, exploring how to secure cutting edge skills, the right access to data, and opportunities from emerging technologies for the geospatial sector itself
2. **Enhancing the UK's geospatial assets,** looking at how best to align interests, avoid duplication, and instill best practice across the whole public sector
3. **Driving investment and productivity in geospatial applications**, asking in which wider sectors the most value lies from better exploitation and use of geospatial data, in the UK and internationally

Our questions

Q1. Is our view of the geospatial data types accurate? If not, what should be included or excluded from this?

In my view the word "place" in the definition of geospatial data is a little too vague and should be replaced by "location".

Q2. In addition to current government policy, what are the areas of geospatial skills where the commission could best focus, to help ensure the necessary capability within the UK for the future?

Promote understanding of the importance of data, data quality and data management.

Improving awareness of the importance of geospatial skills amongst those responsible for managing organisations that create, maintain and consume geospatial data.

Q3. What are the geospatial skills needs and gaps in your organisations, how can these be most effectively addressed, and how can careers in the sector be best promoted?

Awareness amongst senior managers of the benefits of geospatial technologies to improving efficiency and service quality. Provide senior managers with info on case studies and best practice by all available means.

Facilitating GIS Apprenticeships (for newcomers to the profession of ALL ages!) would be very helpful and bring geospatial skill development into line with other skill streams.

Q4. Are there any publicly or privately-held geospatial datasets that are currently challenging to access or use or of insufficient quality, but which you or your organisation would find valuable if these issues could be resolved? Please explain why this would be of value, and how access/quality could be improved?

Access to Land Registry title ownership data would be mutually beneficial in identifying and registering council-owned land holdings and also improving service delivery for cases of fly-tipping and graffiti removal etc.

Q5: Do you anticipate that any changes will be needed to the both address data and the wider address ecosystem, to support emerging technologies? Please provide evidence of value to support any proposed changes.

As an address creating authority and PSMA member our address data needs are currently well met, largely thanks to the PAF Public Sector Licence. I suspect private sector developers of new geospatial technologies may take a different view!

Q6: How should the commission be looking to develop the UK's capability in Earth observation data, both technologically and to support an effective market?

No comment

Q7. Which new technologies should the commission focus on to provide new opportunities to process and exploit geospatial data for economic growth?

No comment

Q8. How can geospatial data and applications be used to support enhanced roll-out of future technologies?

No comment

Q9: What are the options for how public sector organisations could continue to invest in maintaining and enhancing our geospatial data assets?

Ten years of cuts to council funding have greatly reduced the resources available for creating and maintaining address data. Given the importance of accurate address data to geospatial technologies, both current, emerging and as yet unknown in the future, this cannot continue. Ways must be found to fund this work adequately otherwise address data quality will decline to a point at which it is not fit for purpose. Options include enabling councils to receive revenue from those who sell address data and/or charging for the creation and distribution of new addresses by Street Naming and Numbering Officers. A consistent, nationwide approach is needed to this issue.

Q10: What areas of the underpinning geospatial infrastructure such as positioning technologies, including GPS and indoor positioning systems, and geodetic networks and frameworks to support them, should we be prioritising the development of, in order to support the emerging requirements for geospatial data?

No comment

Q11: What role should the private sector have in both the development and maintenance of the underpinning infrastructure and enhancing the UK's geospatial data assets?

The private sector has a considerable role to play both as a provider of leading-edge infrastructure technology (satellites etc) and as a provider of technology and services to the Commission's Partner Bodies and other customers.

Q12. Do you face challenges when working with geospatial data from across the public sector? If so, what are they and how could value be better released? Are there any technical remedies or standards that could be adopted to improve the interoperability of geospatial data? Please provide supporting evidence of what these remedies could help to accomplish.

Use of the AddressBase Premium UPRN/USRN in ALL public sector geospatial datasets would greatly facilitate information sharing leading to improved efficiency, service delivery and reduced losses due to undercollection and fraud. Eg the UPRN in VOA data would greatly aid the identification of untaxed commercial premises.

Q13. How can the Geospatial Commission act as a more effective customer for geospatial data on behalf of the public sector?

Maintain the PSMA and PAF PSL.

Q14. Are there any additional geospatial datasets, from the other partner bodies or other sources, that the public sector would derive significant benefit from having access to, that might have novel and valuable use cases? What would that access look like?

Access to Land Registry title ownership data would be mutually beneficial in identifying and registering council-owned land holdings and also improving service delivery for cases of fly-tipping and graffiti removal etc.

Q15: How can we best develop a single UK strategy, ensuring alignment between the individual strategies across the UK while still allowing for regional variations?

No comment

Q16: How can we best ensure effective local authority coordination and sharing of best practise, using location data to better deliver public services?

Do everything possible to make senior managers and elected members aware of the benefits of geospatial technologies to their organisations and their customers. Facilitate and encourage investment in the resources required. Warn against the consequences of continued cuts to local authority funding in this area.

Maintain and promote the KHub. Regional events to promote/share best practice.

Q17: As a result of this analysis, we are prioritising the exploration of possible initiatives in the high-value categories identified:

- **property and land**
- **infrastructure and construction**

- **mobility**
- **natural resources**
- **sales and marketing**

What are the existing or potential geospatial applications which could be scaled-up or developed in order to capture economic value? (We would particularly welcome responses from industry and other bodies engaged in these sectors.)

No comment

Q18: Are there any other areas that we should look at as a priority?

No comment

Q19: What are the main potential private and public sector innovations that will rely on the use of geospatial data to rollout, and are there corresponding regulatory challenges?

Smart Cities/Districts, Autonomous Vehicles, drones etc. Many regulatory challenges around safety, responsibility for issues arising from poor data quality etc.

Q20: How best can we make the UK's presence in the international geospatial world more visible?

No comment

Q21: Where should the UK be looking for points of comparison overseas? Who are the other international exemplars? What best practice is being modelled overseas that we can learn from?

No comment

Thank you for your time in completing your response to our call for evidence.

Call for evidence - three key themes

We have identified three high-level themes that could help our approach to setting a strategy which are as follows:

1. **Supporting innovation in the geospatial sector**, exploring how to secure cutting edge skills, the right access to data, and opportunities from emerging technologies for the geospatial sector itself
2. **Enhancing the UK's geospatial assets,** looking at how best to align interests, avoid duplication, and instill best practice across the whole public sector
3. **Driving investment and productivity in geospatial applications**, asking in which wider sectors the most value lies from better exploitation and use of geospatial data, in the UK and internationally

Our questions

Q1. Is our view of the geospatial data types accurate? If not, what should be included or excluded from this?

Yes

Q2. In addition to current government policy, what are the areas of geospatial skills where the commission could best focus, to help ensure the necessary capability within the UK for the future?

Processing of earth observation data – there is an increasing wealth of data, but limited skills to process it effectively.

Automating use of GIS (so not just point and click) via use of command line.

Skills beyond GIS being just software commands notably understanding CRS

Q3. What are the geospatial skills needs and gaps in your organisations, how can these be most effectively addressed, and how can careers in the sector be best promoted?

Not answered

Q4. Are there any publicly or privately-held geospatial datasets that are currently challenging to access or use or of insufficient quality, but which you or your organisation would find valuable if these issues could be resolved? Please explain why this would be of value, and how access/quality could be improved?

Biggest issue is:
Large scale mapping – ie Mastermap. A good map is the starting point for any land based project. It enables us to understand what is there, and put all the data generated for the project in the best context – helping make better decisions.

In my field we also need largest scale geological data available (1:50K is useful, but 1:10K would be better). We can WMS 1:50K, but getting 1:10K is a visit to BGS for a paper map, which you probably aren't allowed to put in your GIS

Coal Authority data can currently be accessed via interactive map, but would be more useful as open data to go into GIS.

Aquifer data and Source Protection Zones are currently available via MAGIC, but need to be downloadable OGL

Price is a barrier and so are licence conditions.

Data needs to be able to flow freely through professionals, so we can build on each others work and not have to repeat part of it. At the moment, for every project we do, we see multiple professioinals working on maps, plotting proposed buildings, borehole locations, contamination results, archaeological features etc. And then printing the resuits in reports as pdfs. The next person in the chain then has to import the pdf, and georegister it (slow, inaccurate). They should just be able to import the required data layer.

Paying for the underlying mapping, means you have to sign a licence agreement and that often means you cannot get / provide the data from those before / after you in the chain.

The licence needs to be OGL

And if an acknowledgement is needed, this should automatically appear – ie be attached to the data in some way. Otherwise someone has to check what the acknowledgement is, add a text box etc.

Q5: Do you anticipate that any changes will be needed to the both address data and the wider address ecosystem, to support emerging technologies? Please provide evidence of value to support any proposed changes.

Not answered

Q6: How should the commission be looking to develop the UK's capability in Earth observation data, both technologically and to support an effective market?

At the moment searching for useful EO data is so time consuming and often unrewarding. Yet we all know it has potential

First step is portal to quickly access EO data. High quality search and filter techniques. Quick method to screen out clouds. Choose wavelength. Clear indication of resolution. Ability to snip area for download eg shapefiles, drawline.

One option to develop capability is to provide tutorial on demonstrably useful datasets accessible from the portal

Q7. Which new technologies should the commission focus on to provide new opportunities to process and exploit geospatial data for economic growth?

Not answered

Q8. How can geospatial data and applications be used to support enhanced roll-out of future technologies?

Not answered

Q9: What are the options for how public sector organisations could continue to invest in maintaining and enhancing our geospatial data assets?

Not answered

Q10: What areas of the underpinning geospatial infrastructure such as positioning technologies, including GPS and indoor positioning systems, and geodetic networks and frameworks to support them, should we be prioritising the development of, in order to support the emerging requirements for geospatial data?

LoraWan eg Things network. This has capability to offer geolocation without GPS (based on triangulation with 3 things network gateways).

EG every council could put up one things network gateway in their county town as a starting point, from which other organisations and individuals could build.

Q11: What role should the private sector have in both the development and maintenance of the underpinning infrastructure and enhancing the UK's geospatial data assets?

Not answered

Q12. Do you face challenges when working with geospatial data from across the public sector? If so, what are they and how could value be better released?

Are there any technical remedies or standards that could be adopted to improve the interoperability of geospatial data? Please provide supporting evidence of what these remedies could help to accomplish.

Biggest problem is accessing data from data.gov.uk is time consuming and a bit of a lottery. For a start the search is not very sophisticated, so there can be too many datasets. Needs advanced search with AND OR NOT etc.

Much worse, is that SO MUCH data is unavailable so if you are searching on spec, you can spend a lot of time to no benefit. This should be able to be filtered out on the front page. I have particularly struggled accessing LIDAR and Digital elevation models. I believe they are there, but I cant easily find them – I often end up with a promising looking file being unavailable.

Also some datasets are done by local authority; this may be how the are collected, but you will struggle to find the local authority you want, due to the poor search facility. A filter by local authority is essential.

Sometimes you have to register – eg historic England. If that is really necessary – there should be one registration via data.gov.uk that gets transmitted to the other organisations

Multiple different licences eg EA Conditional Licence – it takes time to decide what you can/cant do – this needs to be simplified as much as possible to be useful. The result of complex licencing is that some will use it and ignore it/ others will take lots of time (ie productivity loss) trying to comply /others will not bother to use the data as compliance is too complex – especially if you need to be able to pass the data onto others eg for planning/development..

Spatial data catalogue is very useful
https://environment.data.gov.uk/ds/catalogue/index.jsp#/catalogue
But redesign to allow multiple downloads eg all flooding datasets, would save so much clicking

If the data was easier and less time consuming to sift through, it would be more likely to be included in a GIS and used to analyse the problem at hand.

Q13. How can the Geospatial Commission act as a more effective customer for geospatial data on behalf of the public sector?

Not answered

Q14. Are there any additional geospatial datasets, from the other partner bodies or other sources, that the public sector would derive significant benefit from having access to, that might have novel and valuable use cases? What would that access look like?

Slightly concerned that this question implies that the public sector will have access to data, that will not be open.

Currently, when working for the public sector, if they have data, that they would like us to use to assist with the problem at hand, we often get stuck at the licencing issue described above; this delays things (productivity again).

Q15: How can we best develop a single UK strategy, ensuring alignment between the individual strategies across the UK while still allwoing for regional variations?

Where data clearly crosses boundaries, it makes sense to have a single UK approach – eg air quality, wind speed, water flows (all fluids). Many physical features would benefit from UK approach – topography, rivers. Where data is collected on an administration boundaries, this can be more flexible, allowing for creativity and learning from each other.

Q16: How can we best ensure effective local authority coordination and sharing of best practise, using location data to better deliver public services?

Not answered

Q17: As a result of this analysis, we are prioritising the exploration of possible initiatives in the high-value categories identified:

- **property and land**
- **infrastructure and construction**
- **mobility**
- **natural resources**
- **sales and marketing**

What are the existing or potential geospatial applications which could be scaled-up or developed in order to capture economic value? (We would particularly welcome responses from industry and other bodies engaged in these sectors.)

Brownfield redevelopment, geotechnical assessment, environmental assessment, archaeological assessment

Q18: Are there any other areas that we should look at as a priority?

Air Quality
Water Quality
Hazard Management

Q19: What are the main potential private and public sector innovations that will rely on the use of geospatial data to rollout, and are there corresponding regulatory challenges?

Everything to do with assessing land – including redevelopment, energy, minerals, conservation.

Regulatory challenge is clarity and easy technological solution to what data you can/cant pass to others.

Transport – potential for revolutionising public transport by providing better information. Eg what bus could I get from near where I am. This can be done via google maps, but it is a frustrating experience.

Q20: How best can we make the UK's presence in the international geospatial world more visible?

Not sure about 'best', but some suggestions are:

Geospatial commission youtube channel show casing new datasets, and what has been done with them

Futurelearn (since that is our own Open University) MOOC on using open data

Q21: Where should the UK be looking for points of comparison overseas? Who are the other international exemplars? What best practice is being modelled overseas that we can learn from?

Google maps – at the moment this is the go to place for mapping; many use the google api for mapping applications. As we have Mastermap which is much much better, we should aim for mastermap to be the go to data /app /api for UK mapping.

Thank you for your time in completing your response to our call for evidence.

Any questions, please get in touch with the Geospatial Commission via geospatialcommission@cabinetoffice.gov.uk

Call for evidence - three key themes

We have identified three high-level themes that could help our approach to setting a strategy which are as follows:

1. **Supporting innovation in the geospatial sector**, exploring how to secure cutting edge skills, the right access to data, and opportunities from emerging technologies for the geospatial sector itself
2. **Enhancing the UK's geospatial assets,** looking at how best to align interests, avoid duplication, and instill best practice across the whole public sector
3. **Driving investment and productivity in geospatial applications**, asking in which wider sectors the most value lies from better exploitation and use of geospatial data, in the UK and internationally

Our questions

Q1. Is our view of the geospatial data types accurate? If not, what should be included or excluded from this?

The referred geospatial data types appear accurate at a high level, however as with all data it is not only important to consider the type of data but where it is sourced and the intended use. Without considering the intended use it is almost impossible to deliver value. An additional concern is that when presenting descriptors at a high level there is a risk of ambiguity as to what category a dataset may fall into, more detailed descriptors or current examples may be useful in this case.

Based on some of the considerations above, a "metadata" data type could be included. This data type facilitates better understanding of a dataset, providing context on the collection method, maintenance, currency and its limitations. Enabling data users access to this information is crucial for delivering reliable and accurate products and services to every industry.

Q2. In addition to current government policy, what are the areas of geospatial skills where the commission could best focus, to help ensure the necessary capability within the UK for the future?

There are several areas that the Commission should target to improve capability within the UK, the first of these is visibility of the sector and perceived benefits outside of traditional use cases. The Commission should work with existing and emerging technology companies to highlight the benefits of employing geospatial professionals. This could be completed by marketing high profile case studies and how value was delivered through geospatial data and techniques.

Landmark host a GIS Day event annually which gains high engagement, the Commission could support days such as this to promote GIS nationally.

Another area of focus should be around education and accreditation. The Commission should establish or promote the provision of professional qualifications to maintain talent with the sector and in turn drive the sector forward. Promoting geospatial content within schools and universities and in particular courses such as Information or Data Science will provide talent to the sector from less traditional routes.

Alignment of practices and consistency across central and local government in respect to the data that is produced and made available to support innovation is important. However, capital investment in information systems may also be necessarily to ensure the necessary system capabilities exist.

Q3. What are the geospatial skills needs and gaps in your organisations, how can these be most effectively addressed, and how can careers in the sector be best promoted?

The largest requirement is in relation to experience and domain knowledge. An appreciation of the increasing capabilities of GI technologies and base data domain knowledge is rare but both are crucial skills for enabling innovation.

Highlighting that this sector is not only for traditional geospatial careers but supports a wide variety of modern job roles will address existing views of the sector. It is important to work with public and private organisations to effectively market and distribute job opportunities.

The Commission should promote the sector early and improve access to GIS and geospatial skills in the early curriculum.

Q4. Are there any publicly or privately-held geospatial datasets that are currently challenging to access or use or of insufficient quality, but which you or your organisation would find valuable if these issues could be resolved?

Please explain why this would be of value, and how access/quality could be improved?

When considering which geospatial datasets to prioritise the following factors should be reviewed: “reference” datasets, blockers to market, public cost of creation, benefits to real world users and existing services and commercial markets.

Key “reference” datasets should be targeted under a flexible and transparent licencing regime that is easy to understand. Reference datasets such as addresses, commercial ownership and ratings will unlock derived data and varied opportunities.

Research into blockers should be undertaken, but it is important to understand what is constraining innovation, i.e. whether it is a question of absolute cost, or whether the licensing regime is too complex, or whether the quality and consistency of the data is insufficient. The Commission should not always look to improve access by making data free, indeed in many cases it will make sense to continue to charge for the data (e.g. a cost recovery basis) to ensure quality is not impaired.

“Raw” data collected as part of a public or statutory duty should be made available at nil or minimal cost, an example of this is the flood maps generated by local authorities as part of the NPPF. This will in turn empower private organisations to innovate and deliver value to real world users.

The public and dataset users should be consulted to prioritise the roadmap for updates. The ability for the public to submit requests for datasets to be published and the additional ability for people to vote for specific request would provide highly insightful information. Alternatively consider value based on the number of downloads from data.gov.uk and prioritise accordingly, the results of which should be available to the public sector to drive innovation.

The final consideration for prioritisation should be around what existing services and markets already exist around datasets. If the private sector has created a solution that provides value to the market, the Commission should strive to unlock new value and opportunities as opposed to replicating what is available.

The Commission could improve the quality of datasets where content and availability varies between government organisations, e.g. content and availability of planning application data from local authorities, or consistent release of flood map data in the UK (EA, NRW release as open data, whereas SEPA do not). Standardising datasets would ensure equal benefits across the UK.

Further quality improvements could be made through training, investment in infrastructure, clear national policies on data collection and maintenance, consistent content, transparent metadata, feedback mechanisms.

Q5: Do you anticipate that any changes will be needed to the both address data and the wider address ecosystem, to support emerging technologies? Please provide evidence of value to support any proposed changes.

This data needs a flexible and transparent licence, the current model can act as a blocker to innovation and increases development costs due to the need to record transactions for royalty purposes. This applies to both the address and its associated coordinates.

Standardising the market for non-addressable features is important. A uniform approach to how to categorise non-addressable features will support land and property transactions and ensuring emerging technologies are developed in a long-lasting capacity.

Q6: How should the commission be looking to develop the UK's capability in Earth observation data, both technologically and to support an effective market?

The Commission should support this capability in a number of ways: data collection, removing technology blockers, supporting access and supporting the diversification of collection methods.

The Commission should aim to give greater priority to the capture of high-resolution aerial imagery within the UK via policies which encourage Air Traffic Control to better accommodate these types of flight.

In the past earth observation data has been very expensive and not very accurate. The promotion of new technologies and improved data accuracies need to be promoted, also the high commercial barrier to entry could be reduced through subsidies or support. However, it is still imperative to highlight the data that is available and the restriction on use.

Access could be improved through the development of image/data repositories with easy freely available access to these image libraries, e.g. portals or API. The repositories should offer standard image processing, e.g. estimation of cloud cover so that users can select suitable images/data for their requirements, NDVI, True Colour, analytical image downloads. The Commission should support the private sector in delivering innovative and appropriate solutions to market.

The Commission should develop the collaboration of data collectors to improve overall coverage and increase update frequency.

Q7. Which new technologies should the commission focus on to provide new opportunities to process and exploit geospatial data for economic growth?

Develop or make available higher resolution satellite imagery, more frequent high-resolution imagery ensures that it can be regularly relied upon and valuable services can be built upon it.

Supporting the roll out of 5G will provide reliable connections to utilise geospatial data anywhere. The opportunities to stream and utilise large datasets in the field will provide crucial benefit to the land and property sector.

Q8. How can geospatial data and applications be used to support enhanced roll-out of future technologies?

Geospatial data and applications support the identification, visualisation and analysis of opportunities with the biggest potential value. However, it is imperative that the following should be in place to enable this:

- Data that is accessible with flexible and transparent licensing
- Data that is not held in proprietary formats and the format is easily accessible
- Information on what the data is, its limitations and where it came from is available in the metadata

Q9: What are the options for how public sector organisations could continue to invest in maintaining and enhancing our geospatial data assets?

The public sector should consider the following when investing in geospatial data: consolidation, private sector involvement, historical value, charging and technology.

It is imperative to limit the repetition or over-collection of data and to consider the value the data delivers when collecting. A focus should be made to maximise utilisation and avoid duplication when creating data. The public sector (and end users) would benefit from the creation of common standards regarding data collection and attribution, this would reduce complexity of utilising national scale data.

The public sector should continue their focus on core duties and create a model for outsourcing tasks to the private sector. This would improve data feedback loops, improve innovation in the market and reduced competition between the public and private sector.

Digitisation of historic paper records where a demand or need exists represents an opportunity to deliver unique and highly valuable data to the market.

Where cost prevents the collection and improvement of data required within the public duties of the sector then funding from central government should be made available. Where costs are incurred outside their public duties these could be passed onto the data purchaser on a cost recovery basis, in certain situations it may be appropriate for government subsidies if the product costs are high.

Investment within emerging AI technologies for quality assurance and data capture offer opportunities to save significant costs and provide valuable reassurance for the quality of data.

Q10: What areas of the underpinning geospatial infrastructure such as positioning technologies, including GPS and indoor positioning systems, and geodetic networks and frameworks to support them, should we be prioritising the development of, in order to support the emerging requirements for geospatial data?

The support of existing infrastructure and technologies such as OS Net and national transformation (e.g. OSTN) should drive the way in accelerating the UK's position in this space.

The Commission should prioritise the creation and development for national standards across addressing, indoor and outdoor positioning. National standards will promote efficiency in the creation of market wide solution and support innovation in the sector.

It is important to consider appropriate data privacy oversight, to ensure emerging technologies and solutions are not blocked by uncertainty.

Q11: What role should the private sector have in both the development and maintenance of the underpinning infrastructure and enhancing the UK's geospatial data assets?

The private sector should provide the back-bone for development and delivery of the UK's geospatial assets. Commercial models to support the costs required to maintain, deliver and improve the highest quality geospatial assets are imperative to ensure the UK retains a leading position in delivering geospatial excellence.

Working with the private sector to increase accessibility of data drives innovation for delivery and provides increased value to market.

Landmark has added significant value to the geospatial market for over 20 years, there are numerous projects that highlight the value of the involvement of the private sector. Examples of these include:

- Landmark's delivery of the EPC, Magic and DEFRA portals. These contracts were awarded by government agencies for the provision of services and resource to support the public.
- Significant improvements to change detection techniques have been developed through partnerships. For example, the Landmark / OS Historical Mapping Joint Venture.
- Finally, Landmark's value-added reseller model has provided significant revenue to government agencies through the payment of royalties. e.g. OS, BGS and the EA.

Q12. Do you face challenges when working with geospatial data from across the public sector? If so, what are they and how could value be better released? Are there any technical remedies or standards that could be adopted to improve the interoperability of geospatial data? Please provide supporting evidence of what these remedies could help to accomplish.

Inconsistencies of working practices across departments present a challenge as this often results in different levels of detail being supplied by different authorities for the same dataset.

Inconsistent policies on the release of data, including that held by both central government and local authorities, cause difficulties in managing effective, reliable and up to date data.

The devolution of responsibility causes fragmentation of supply of datasets causing data to be sourced from multiple locations.

Q13. How can the Geospatial Commission act as a more effective customer for geospatial data on behalf of the public sector?

By procuring geospatial data on behalf of the public sector, the Commission can negotiate improved, more transparent and uniform terms.

The Commission should look to define standards and specifications for geospatial data, and this should include attribution, collection and maintenance, which would improve support to economies of scale. Standards could also include recording of what has been captured, created and purchased.

By acting on behalf of the public sector the Commission would be able to lead the sharing of geospatial knowledge across the sector, this would also support the rollout of market standards.

Q14. Are there any additional geospatial datasets, from the other partner bodies or other sources, that the public sector would derive significant benefit from having access to, that might have novel and valuable use cases? What would that access look like?

Datasets that would be useful to improve access to include:

- Access to key local authority geospatial datasets that relate to e-conveyancing and the Ministry of Housing, Communities and Local Government's policy paper 'Fixing our Broken Housing Market'
    - Planning Applications
    - Building Regulation
    - Planning Appeals
    - Local Development Frameworks & Plans
    - TPOs
- Access to underground assets, e.g. potable water and sewerage networks etc
- Access to national infrastructure datasets, e.g. Cross Rail 2, Thames Tideway
- Access to high resolution datasets which are prevented by licencing issues, e.g. postcode level broadband information
- Access to archaeological datasets held at a local and unitary authority level
- Access to historical aerial imagery held by local and unitary authorities
- Access to the National Street Gazetteer
- Petroleum tanks licensing
- Residential and commercial ratings information
- Access to environment datasets published by SEPA
- National and Local Flood models produced by the various environment agencies
- Rural Payments Agency datasets – e.g. Single Business Identifier and land parcel reference number etc

Q15: How can we best develop a single UK strategy, ensuring alignment between the individual strategies across the UK while still allwoing for regional variations?

Quality standards will support the alignment of individual strategies across the UK. There needs to be coordination for all parts of the UK, the public sector and the private sector.

We recommend that the Commission review similar agreements, for example:

- One Scotland Mapping Agreement
- Joint Emergency Services Group in Wales

Q16: How can we best ensure effective local authority coordination and sharing of best practise, using location data to better deliver public services?

The creation of a regulated Geospatial code and standards would ensure uniform data and process between different local authorities. Adequate funding and commercial benefits for authorities who implement such standards would ensure that these are upheld.

Q17: As a result of this analysis, we are prioritising the exploration of possible initiatives in the high-value categories identified:

- **property and land**
- **infrastructure and construction**
- **mobility**
- **natural resources**
- **sales and marketing**

What are the existing or potential geospatial applications which could be scaled-up or developed in order to capture economic value? (We would particularly welcome responses from industry and other bodies engaged in these sectors.)

It is our opinion that the Commission should target the blockers to enabling innovation and the creation of geospatial applications by the private sector as opposed the delivery of such. For example, while Ownership data is licensable, local development plans are difficult to manage, varied and not readily available. Additionally, local authorities often hold valuable historical data within hardcopy and archived records. The Commission should evaluate how to unlock this value, through either public sector engagement or private sector contracts.

Q18: Are there any other areas that we should look at as a priority?

- Environmental
- Historical
- Navigation

Q19: What are the main potential private and public sector innovations that will rely on the use of geospatial data to rollout, and are there corresponding regulatory challenges?

Landmark continue to add value to geospatial data, and we welcome the opportunity to work with the Geospatial Commission and Geo-6 on methods of delivery innovation to the industries. For example, delivering on the requirements for highlighting available land for development alongside improvements to the planning process are crucial innovations. These are currently limited by the lack of standardised data and alignment within local development planning.

Landmark has a history of delivering innovations built upon geospatial data. Promap, Envirocheck, RiskView Residential and SearchFlow are all leading innovations that expand the reach and use case of geospatial data within their respective markets. Not only this but Landmark have also directly assisted government in improving the accessibility of data, for example MAGIC & DEFRA portal.

Q20: How best can we make the UK's presence in the international geospatial world more visible?

It is crucial to represent the best of the UK's geospatial presence with high profile case studies, these should highlight both technological innovations or projects that exhibit best practice.

The Commission should look to create centres of excellence within the UK industry that enable collaboration, innovation and investment within the geospatial industry.

Q21: Where should the UK be looking for points of comparison overseas? Who are the other international exemplars? What best practice is being modelled overseas that we can learn from?

Singapore have created a Geospatial Master Plan, this presents a baseline assessment of Geospatial of Policy, Data and Institutions, Capacity and Adoption and Platforms and Technology. Within this is also clearly presents the requirement to support both start-ups and established corporations to drive the innovation and opportunities.

Thank you for your time in completing your response to our call for evidence.

Any questions, please get in touch with the Geospatial Commission via geospatialcommission@cabinetoffice.gov.uk

Geospatial Commission: Call For Evidence Response Questionnaire

Please submit your completed questionnaire to:

Telephone	[Text redacted]

Please select which of the following best describes you as a respondent:

Respondent	**Please mark with a X**
Academic	
Business representative / trade body	
Central government	
Charity or social enterprise	
Individual	
Legal representative	
Local government	
Large business (over 250 staff)	
Medium business (50 to 250)	
Small business (10 to 49)	**x**
Micro business (up to 9)	

Other - please state	

Call for evidence - three key themes

We have identified three high-level themes that could help our approach to setting a strategy which are as follows:

1. **Supporting innovation in the geospatial sector**, exploring how to secure cutting edge skills, the right access to data, and opportunities from emerging technologies for the geospatial sector itself
2. **Enhancing the UK's geospatial assets,** looking at how best to align interests, avoid duplication, and instill best practice across the whole public sector
3. **Driving investment and productivity in geospatial applications**, asking in which wider sectors the most value lies from better exploitation and use of geospatial data, in the UK and internationally

Our questions

Q1. Is our view of the geospatial data types accurate? If not, what should be included or excluded from this?

I would only add that many of these forms may also have a temporal aspect but this doesn't detract from the spatial interactions defined.

Q2. In addition to current government policy, what are the areas of geospatial skills where the commission could best focus, to help ensure the necessary capability within the UK for the future?

As a part of the land and building survey sector and a member of “The Survey Association”, it is troubling that courses in geomatics appear to be closing down. I believe Mike Skicko at Leica is also pressing this point. There are some issues even recognising this as a profession for example even down to CSCS cards for site access.

I think additional education of creating API services might also benefit many in the community who could release powerful tools as easily consumable functions.

Q3. What are the geospatial skills needs and gaps in your organisations, how can these be most effectively addressed, and how can careers in the sector be best promoted?

It seems many organisations have little time for their staff to focus on learning as they have to get the day job done. It’s often the case that we hear of companies who only managed to introduce new techniques be personnel taking the initiative and working out of hours on their own projects. I’m not sure that this isn’t just a cultural failing in certain industries.

We supported a colleague through an MSc recently but it is a significant commitment on their part and it would be good to see more private sector orientated one-two day courses. I do see a number of companies running public sector orientated versions.

Q4. Are there any publicly or privately-held geospatial datasets that are currently challenging to access or use or of insufficient quality, but which you or your organisation would find valuable if these issues could be resolved? Please explain why this would be of value, and how access/quality could be improved?

Land Registry currently require 20k annually to take their national polygons dataset (admittedly they allow free access for development) and offer no margin on things like deeds information. This works in particular for conveyancing software where there is significant value in the software and in tying users in. For developing bespoke applications it is more challenging and has certainly led us to developing other solutions first where we think we could have done more had a transactional model been in place and ideally allowing some margin to cover the costs of introducing beneficial customer functionality.

Planning information and in particular designated areas from the likes of local plans should be much more simply accessible as there is considerable waste in competiting organisations scraping this information.

Q5: Do you anticipate that any changes will be needed to the both address data and the wider address ecosystem, to support emerging technologies? Please provide evidence of value to support any proposed changes.

Given that the UK addressing system is so well established, it is sad to see the need for the likes of WhatThreeWords for location. The latter allows no understanding of relative location in the way that postcode area, sectors and districts does.
Some sort of linking of addressing to highly accurate locations will presumably also be needed for autonomous delivery or even vehicle parking.

Q6: How should the commission be looking to develop the UK's capability in Earth observation data, both technologically and to support an effective market?

A key concern would be that any joint investment through the EU is not lost due to restrictions in data access through Brexit.
We are beginning to see products appear relating to subsidence monitoring and flooding extents which show promise for meaningful solution accessible by users and industry.

Q7. Which new technologies should the commission focus on to provide new opportunities to process and exploit geospatial data for economic growth?

I'm personally excited by the work of Gaist. Their capture of road condition (from vehicle mounted cameras) looks to be a fantastic means to reduce wasted public funds which are often patching problems inefficiently leaving less money for actually improving the situation. It is one of the few technologies I have seen recently which I truly believe could fundamentally improve outcomes for all.

I appreciate this might not be considered earth observation data but it is significant national level capture of big data with benefits recognised through machine learning.

Q8. How can geospatial data and applications be used to support enhanced roll-out of future technologies?

Q9: What are the options for how public sector organisations could continue to invest in maintaining and enhancing our geospatial data assets?

I have some concerns that removing costs to end users for large scale information such as that of Ordnance Survey could ultimately devalue it's worth and lead to the funding and upkeep of it's quality becoming a politically influences decision. One of the true signs that it retains it's value to so many is that people are still willing to pay for the data.

Q10: What areas of the underpinning geospatial infrastructure such as positioning technologies, including GPS and indoor positioning systems, and geodetic networks and frameworks to support them, should we be prioritising the development of, in order to support the emerging requirements for geospatial data?

Q11: What role should the private sector have in both the development and maintenance of the underpinning infrastructure and enhancing the UK's geospatial data assets?

I think it is crucial that the private sectors value should not be overlooked, particular where work is already being done which can benefit all. Particularly, it is concerning where government department begin attempting to serve requirements for which private companies have an established market.

Disappointingly, some of those organisations who are seen as making their information freely available such as Google do not actually enable use of the data except through their own systems.

Q12. Do you face challenges when working with geospatial data from across the public sector? If so, what are they and how could value be better released? Are there any technical remedies or standards that could be adopted to improve the interoperability of geospatial data? Please provide supporting evidence of what these remedies could help to accomplish.

Our main concern is simply that there is consistency in how data is delivered to accelerate visibility and consumption. It is also important that the data is updated and that it is clear that this happening to the user who may not know whether a dataset has not been updated due to it being unsupported vs it simply being midway to the next delivery cycle.

There can also be some confusion where datasets have significant overlap. A potential issue is forthcoming with the planning open data OS is required to offer relating to property polygons. There will be confusion for users in understanding the difference between these (not legally based), the Land Registy and the versions held within Local Authorities. A lack in clarity of the purpose of such data will inevitably lead to questions concerning the reliability of the source agency.

Q13. How can the Geospatial Commission act as a more effective customer for geospatial data on behalf of the public sector?

Q14. Are there any additional geospatial datasets, from the other partner bodies or other sources, that the public sector would derive significant benefit from having access to, that might have novel and valuable use cases? What would that access look like?

I think some caution may be needed in this area to ensure the use of a single private source leading to that provider being seen as de facto in the industry as a result. OS for example is just releasing speed data for it's OS Highways. Whilst I recognise and intend to utilise the benefits, I do have some concern that the commercial partner will as a result become market dominant. It might be better to highlight private entities who have been shown to offer a viable dataset in combination with the public data. This would drive others to ensure their data was equally as compliant.

Q15: How can we best develop a single UK strategy, ensuring alignment between the individual strategies across the UK while still allwoing for regional variations?

Q16: How can we best ensure effective local authority coordination and sharing of best practise, using location data to better deliver public services?

Q17: As a result of this analysis, we are prioritising the exploration of possible initiatives in the high-value categories identified:

- **property and land**
- **infrastructure and construction**

- **mobility**
- **natural resources**
- **sales and marketing**

What are the existing or potential geospatial applications which could be scaled-up or developed in order to capture economic value? (We would particularly welcome responses from industry and other bodies engaged in these sectors.)

Whilst Open MasterMap appears to have been identified as a requirement to open greater property/land development it is generally the higher level consideration of both restricted and supported zones of development which are considered in identifying areas in which to try and realise opportunities.The physical geometry of a site often comes much later and at lower cost in the development chain.

Q18: Are there any other areas that we should look at as a priority?

Q19: What are the main potential private and public sector innovations that will rely on the use of geospatial data to rollout, and are there corresponding regulatory challenges?

Understanding user's position absolutely in things like addressing for autonomous delivery and vehicles and also in marketing will require close consideration of impacting user privacy.

Q20: How best can we make the UK's presence in the international geospatial world more visible?

From my experience the OS and BGS have respect internationally although seemingly even qualified civil engineers in Great Britain are unaware of the availability of the BGS services and data to the extent that non geologists create 3D geological models for projects.

If the open data and solutions around that can be made viable as internationally applied formats then many countries will appreciate the benefits of having a template to adopt.

Q21: Where should the UK be looking for points of comparison overseas? Who are the other international exemplars? What best practice is being modelled overseas that we can learn from?

I am always impressed by the Swiss mapping agency and look at their implementations as offering inspiration.

I'm also surprised how good Norwegian building data is in capturing roof structures. Admittedly there are less buildings to maintain but there are clear benefits for instance in understanding solar energy options or liability to snow loading.

Thank you for your time in completing your response to our call for evidence.

Any questions, please get in touch with the Geospatial Commission via geospatialcommission@cabinetoffice.gov.uk

Geospatial Commission: Call For Evidence Response Questionnaire

Please submit your completed questionnaire to:

geospatialcommission@cabinetoffice.gov.uk.

Clearly title your email *'Call for evidence response'*.

About you and your organisation

Name	[Text redacted]
Organisation	Leeds City Council
Job title	[Text redacted]
Address	[Text redacted]
E-mail	[Text redacted]
Telephone	[Text redacted]

Please select which of the following best describes you as a respondent:

Respondent	**Please mark with a X**
Academic	
Business representative / trade body	
Central government	
Charity or social enterprise	
Individual	
Legal representative	
Local government	**X**
Large business (over 250 staff)	
Medium business (50 to 250)	
Small business (10 to 49)	
Micro business (up to 9)	

Other - please state	

Call for evidence - three key themes

We have identified three high-level themes that could help our approach to setting a strategy which are as follows:

1. **Supporting innovation in the geospatial sector**, exploring how to secure cutting edge skills, the right access to data, and opportunities from emerging technologies for the geospatial sector itself
2. **Enhancing the UK's geospatial assets,** looking at how best to align interests, avoid duplication, and instill best practice across the whole public sector
3. **Driving investment and productivity in geospatial applications**, asking in which wider sectors the most value lies from better exploitation and use of geospatial data, in the UK and internationally

Our questions

Q1. Is our view of the geospatial data types accurate? If not, what should be included or excluded from this?

The view appears to be a tiered approach but descriptions are abstract in definition. Could practical examples for each geospatial datatype be provided to aid understanding? We feel that would help make the explanations much clearer.

Q2. In addition to current government policy, what are the areas of geospatial skills where the commission could best focus, to help ensure the necessary capability within the UK for the future?

Introduce concepts of geospatial data at earlier stages in schools, make GIS applications more widely available to schools and ensure that schools have the resources available to be able to teach the subject.

In addition to this could the GC provide/devise a training programme which ties into the current apprenticeship levy within local authorities? Could include the following key areas:

- Basic, transferable skills: data provenance and trustworthiness, data quality (complete, consistent, accurate, etc.); basic database theory (RDBMS, SQL); web services and standards (WMS, etc.).

- Basic geospatial skills: geocoding, spatial analysis, map presentation. Focus on data and process rather than the software.

Another key aspect is having skilled resources in areas of geospatial databases/data warehouses management. A lot of attention is paid to 'what can we do with our data' but the 'how do we acquire/manage our data in the first place' often seems to be the poor relation in terms of organisational focus.

Q3. What are the geospatial skills needs and gaps in your organisations, how can these be most effectively addressed, and how can careers in the sector be best promoted?

Leeds City Council doesnt necessarily have a skills gaps but more resource gaps, in both data management/governance issues and in 'front-line' GIS users. This was covered extensively in a recently commissioned SOCITM report.

One area unexplored/unexploited is what can be done with widely available online mapping tools such as Google maps and how it could enhance the internal GIS ecosystem.

Careers in GIS – start teaching geospatial subject matter earlier and with higher profile in schools, signpost to interesting/exciting/critical examples of geospatial implementations to inspire/motivate.

Q4. Are there any publicly or privately-held geospatial datasets that are currently challenging to access or use or of insufficient quality, but which you or your organisation would find valuable if these issues could be resolved?

Please explain why this would be of value, and how access/quality could be improved?

This answer is made up of multiple suggestions from different areas

- A catalog of regional aerial photography would be useful. LCC holds some aerial data but there is a huge gap spanning a number of years. Having a more complete dataset could be used for educational purposes, planning enforcement cases, monitoring green space and so forth.
- 3D Models are available but vary in their detail, accuracy and coverage. These models could be used for a variety of uses from attracting inward investment from abroad to helping make informed decisions on planning applications. A standard needs to be agreed so models could be built by sharing information from various suppliers.
- Thermal mapping would be useful to target heat poverty, identify illegal dwellings, identify ageing housing stock and degradation of home insulation etc
- Air pollution/air quality data could be used to regulate pollutant emmissions by delineating effects of dust, harmful air pollutants and tackle hot spots.
- Companies such as Experian collect and create substantial amounts of data which would help with profiling, for example identifying areas of financial exclusion and so forth. A free-to-use profiling and segmentation data would be very useful.
- OS Open data and the PSMA has transformed access to spatial data for the better. However, it is time consuming to download and process this data. Time could be saved if the data was delivered differently, for example as a base map web service, or a simplified ready to use address service.
- Land Registry – there are barriers to many processes, particularly in land use planning sector in local government. Land ownership details are valuable knowledge for use in all sorts of situations e.g. promoting housing growth by assisting developers/owners on difficult sites – the whole process is much easier if ownership details are readily available. The best case scenario would be for all title information (ownership info and extent) to be made free and straightforward to access. Full titles documents are not necessarily needed so some scope for Land Reg. to continue to exploit the value of those. A good starting point would be free access to the LR Title Deed polygons, preferably as a web service, such as WFS.
- BGS – again, lots of data is made freely available but only at poor resolution, the best data is licensed and use is restricted – restrictive to many areas of LA work – Contaminated Land, GeoEnvironmental engineering, Ecology, Environment
- Coal Authority – As per BGS

- Google – more work needs to be done to see how far Google resources can be exploited.
- ONS – hold significant geospatial data, could the commission join forces?
- There should be a freely available national address database that is definitive and free to all. Addresses need to include height / floor level data for flood risk management purposes & for the emergency services response teams

Q5: Do you anticipate that any changes will be needed to the both address data and the wider address ecosystem, to support emerging technologies? Please provide evidence of value to support any proposed changes.

It is essential that the key aspects of NAG (UPRN, address, postcode, coordinates, classification) are enabled as open data to promote consistent use of addressing, allow better spatial links to individual addresses and compete with PAF. Making the postcode open will be dependent on agreement from Royal Mail.

Whilst AddressBase is a good product it could be improved by having a one to many relationship between an address and different Organisation names (one limited company with a number of brands, or the growing trend for virtual offices where a company uses an address without having a physical presence in that building). Also a one to many relationship with PAF as one property can often be shown on PAF with two different addresses and postcodes (through terraces with two 'front' doors).

Good progress has been made with the use of the UPRN however the Valuation Office need to be forced to use the UPRN and link data to NAG to improve consistency and joined up working.

Q6: How should the commission be looking to develop the UK's capability in Earth observation data, both technologically and to support an effective market?

Q7. Which new technologies should the commission focus on to provide new opportunities to process and exploit geospatial data for economic growth?

Open data is now embedded in public and private sector organisations. At present the government provides a data sharing platform via data.gov.uk. There are also other platforms such as our own local resource Data Mill North. These contain many and varied datasets. A platform specifically for open geospatial data could be created to host or signpost a range of information. For instance it might notify users when changes to national OS data and aerial photography are made, or aid the discovery of local data. If organised efficiently and updated regularly it could become a central point for obtaining data routinely required.

The advent of web-based mapping platforms has been transformative in the way that we present spatial information and provide location intelligence across a wider range of council services. One of the most interesting applications has been presenting spatially-enabled statistical dashboards allowing data and relevant statistics to be presented and interrogated/filtered by spatial extents. This ties in with other dashboard style applications such as Power BI, and we think that the point at which traditional text/numeral based BI tools meet spatial BI is going to be an interesting one. We should be looking closely at this.

3D mapping is another new technology for Leeds City Council. How best to develop a 3D model for Leeds and what use it can be put to is been investigated currently. We are focusing on town planning, asset management, regeneration, and investment – but could this could be expanded to other areas, for example heritage, conservation, neighbourhood management, etc. A high-resolution LIDAR (or similar) dataset of the UK, that is freely available to public bodies, would be of great use to develop 3D models.

Q8. How can geospatial data and applications be used to support enhanced roll-out of future technologies?

The council already supports multiple small and monolithic systems. Many do not incorporate geospatial technology but could potentially be adapted to do so to great effect. Areas for consideration could be:

- Democracy and participation.
- Emergency planning.
- Service planning.
- Public consultations, citizen involvement.
- Event management, building management.
- Vehicle tracking – we believe some councils do this already.

Q9: What are the options for how public sector organisations could continue to invest in maintaining and enhancing our geospatial data assets?

Having core principals within the authority which lend themselves to supporting and promoting the entire organisation's spatial needs.

Dedicated funding assigned to a medium term vision is the ideal. An initial capital injection to enhance services and establish good practice. Once adopted this forms part of the business overall operating model.

Q10: What areas of the underpinning geospatial infrastructure such as positioning technologies, including GPS and indoor positioning systems, and geodetic networks and frameworks to support them, should we be prioritising the development of, in order to support the emerging requirements for geospatial data?

Q11: What role should the private sector have in both the development and maintenance of the underpinning infrastructure and enhancing the UK's geospatial data assets?

Q12. Do you face challenges when working with geospatial data from across the public sector? If so, what are they and how could value be better released? Are there any technical remedies or standards that could be adopted to improve the interoperability of geospatial data? Please provide supporting evidence of what these remedies could help to accomplish.

Too many local government datasets still don't include the UPRN. It's inclusion would enable the spatial properties within the data and allow for better integration. Many local authorties are restricted by legacy systems that they don't have the funds to update. Legacy systems do not have appropriate fields or capabilities to automate integration with the LLPG. Making funding available to update such software for this purpose would be beneficial.

Projections/transformations can also be an issue, particularly when working with web-based systems. While tools are available to convert from one co-ordinate reference system to another, internal knowledge around this area is limited.

Downloading, processing and maintaining OS base map and address data from OS Open data and PSMA is time consuming and resource hungry. Publicly-available web services for base mapping, and for simplified addressing, would allow geospatial skills to be used more productively elsewhere. OS Zoom stack might be a good solution for easy access to base mapping.

Open data standards for 3D mapping would enable 3D models to be created more easily, and allow models to be used more collaboratively. For example, an open standards-based model for Leeds could be created by the authority, added to by developers, and viewed by stakeholders.

Q13. How can the Geospatial Commission act as a more effective customer for geospatial data on behalf of the public sector?

A few of the cuff suggesstions :

- Centralised purchasing
- Recommend 3rd party suppliers
- Discounted purchasing
- Provide GIS services from a central point
- Facilitate collaboration

Q14. Are there any additional geospatial datasets, from the other partner bodies or other sources, that the public sector would derive significant benefit from having access to, that might have novel and valuable use cases? What would that access look like?

The Valuation Office holds data for commercial premises on floor space (area in square meters) and sells the data commercially as part of the full extract of Business Rates records. The data is really useful for numerous purposes (planning monitoring, assessing flood alleviation schemes, estimating employment data) but is only available as a one off extract, is quite expensive, and does not include change only updates so new full extracts are required everytime. Making this data available within the public sector (similar to PSMA terms) would be really useful.

Making aerial photo data available via the APGB contract makes sense, and it is hugely beneficial that local authorities have access to the most current imagery available. This should continue and would also promote the flying of frequent updates from suppliers.

Segmentation data created by companies such as CACI, Call Credit and Experian would help the Local Authority understand its client base and better meet their needs. Inhouse profiling is curently used but the analysis could be improved with more intelligent data from these external sources.

As mentioned previously, 3D mapping is rapidly developing as a key application and the provision of hi-res DTM/LIDAR data to give full authority wide coverage would aid in this considerably. Having this data freely available will allow the authority to develop and maintain it's own 3D city model at relatively low cost and with a high degree of flexibility, rather than have to follow more expensive alternative routes that involve buying a 3D model externally as a maintained service and the restrictions on IPR etc that go along with that.

Free access to Land Registry records for the public sector. For example LR Title Deed polygon data to help ascertain ownership of flood risk related assets (under section 21 of the 'The Flood and Water Management Act 2010'), and access to the Land Registry's 'e-services' portal to create mailing lists. There can be

hundreds of land owners involved when organising a stretch of river bank maintenance (removal of invasive species / litter picking / flood alleviation schemes) – currently it is an onerous task to identify individual owners to request permission.

As legislated (Flood & Water Management Act 2010, section 21), LCC are required to keep a flood risk asset register of all relevant assets and make this available (i.e. publish on the web, using web mapping). This register includes lots of drainage assets, watercourses, etc. LIDAR data is currently available via the government portal but this tends to follow the main river corridors – fuller coverage would be more useful.

Q15: How can we best ensure effective local authority coordination and sharing of best practise, using location data to better deliver public services?

Leeds City Council has begun to explore wider working possibilities within the region. This has included connecting with Bradford, Wakefield, York, Harrogate, Selby and others and discussing potential for collaboration. The following areas have been tabled:

- Joint technology licensing
- Knowledge and skills sharing
- Project inception and support
- Cost savings & efficiencies

It is early days and there is a lot of enthusiasm to explore how this may best develop. There is a lot of potential in this area which need not be limited to the Yorkshire region alone. Ways forward are still being explored but so far Leeds has committed to lead on a regional forum of interested parties. Leeds can easily provide an online platform for the hosting of related information. As usual resource factors are the limiting factor.

Q16: As a result of this analysis, we are prioritising the exploration of possible initiatives in the high-value categories identified:

- **property and land**
- **infrastructure and construction**
- **mobility**
- **natural resources**
- **sales and marketing**

What are the existing or potential geospatial applications which could be scaled-up or developed in order to capture economic value? (We would particularly welcome responses from industry and other bodies engaged in these sectors.)

As a public sector body, our focus is less on commercial opportunities afforded by geospatial applications, and more on the positive impact they have on the intelligent use and information and data in better decision-making, which ultimately improves service delivery, reduces costs and generates efficiency savings.

The primary ways these benefits can be achieved are:

- improved sharing of data and services in a place-based approach where multiple services/partners collaborate in the spatial analysis of data;
- more intelligent use of location-based data e.g. customer insights and engagement, route optimisation and asset and estate management;
- facilitating the access and use of open data with the ultimate aim to improve better customer services and to promote a self-service approach by citizen and business.

Q17: Are there any other areas that we should look at as a priority?

Q18: What are the main potential private and public sector innovations that will rely on the use of geospatial data to rollout, and are there corresponding regulatory challenges?

Q19: How best can we make the UK's presence in the international geospatial world more visible?

Q20: Where should the UK be looking for points of comparison overseas? Who are the other international exemplars? What best practice is being modelled overseas that we can learn from?

The most comprehensive datasets on the geography of Britain are held by its public mapping service, the Ordnance Survey (OS). In the USA they do not have the same stringent rules that govern mapping data in the UK. In the USA mapping data is made available more freely to commerce. This mapping data has many uses ranging from recreation to scientific analysis to emergency response. Please look at the National Map, The United States Geological Survey (USGS) for more information.

Thank you for your time in completing your response to our call for evidence.

Any questions, please get in touch with the Geospatial Commission via geospatialcommission@cabinetoffice.gov.uk

Geospatial Commission: Call For Evidence Response Questionnaire

Please submit your completed questionnaire to:

geospatialcommission@cabinetoffice.gov.uk.

Clearly title your email *'Call for evidence response'*.

Micro business (up to 9)	

Other - please state	

Call for evidence - three key themes

We have identified three high-level themes that could help our approach to setting a strategy which are as follows:

1. **Supporting innovation in the geospatial sector**, exploring how to secure cutting edge skills, the right access to data, and opportunities from emerging technologies for the geospatial sector itself
2. **Enhancing the UK's geospatial assets,** looking at how best to align interests, avoid duplication, and instill best practice across the whole public sector
3. **Driving investment and productivity in geospatial applications**, asking in which wider sectors the most value lies from better exploitation and use of geospatial data, in the UK and internationally

Our questions

Q1. Is our view of the geospatial data types accurate? If not, what should be included or excluded from this?

We agree with your view.

Q2. In addition to current government policy, what are the areas of geospatial skills where the commission could best focus, to help ensure the necessary capability within the UK for the future?

This is not an area we are qualified to comment on.

Q3. What are the geospatial skills needs and gaps in your organisations, how can these be most effectively addressed, and how can careers in the sector be best promoted?

We partnered with PelicanCorp, an Australian firm in 2012/13 as they were supplying similar services (in our niche area of the industry) to several international regions. We assessed what was available across the World and partnered with the firm to be able to learn from international best practice.

Q4. Are there any publicly or privately-held geospatial datasets that are currently challenging to access or use or of insufficient quality, but which you or your organisation would find valuable if these issues could be resolved? Please explain why this would be of value, and how access/quality could be improved?

We read with interest the 'Data for the Public Good' document as this premise is the foundation for the service that we have run since 2003. In that time, we have helped millions (in excess of 2.5 million searches per annum) of users access the data they need from our 70+ utility Members to help ensure works can take place safely and efficiently. This has helped improve their productivity, supporting economic growth and improving the delivery of public services. Providing that facility whilst satisfying the potential security concerns of our Members (who are responsible for critical national infrastructure) is a foundation to the success of the service.

The assets are often buried in the ground, and in certain cases date back to the Victorian period and earlier. Accordingly, the data can be limited and is varied across organisations. All the previous failed attempts to share this for the public good failed to align the desires of those using the data to the restrictions of those that own that data in the format that it exists in.

We understand the limitations of the UK's buried asset data. We also acknowledge the need to improve it on an on-going basis, and the inherent complexity of doing so. The key area for improvement with this data, however, is behavioural; making the best of the data as it stands and ensuring its accessibility. It is essential data that people rely on to stay safe thousands of times every day, so sharing the 'best available data' as well as possible is every bit as important as improving the data – and an area that is and can be improved now.

The asset owners that have worked collaboratively have found that by joining LSBUD, they have been able to share their data with more third parties than ever before, which provides significant benefits from a reduction in strike damages perspective as well as reduced costs and heightened industry awareness. This has come from creating a model where the user can access data free of charge whilst enabling the utility companies to share such information in a much more cost-effective manner than they could otherwise. It is a business model that benefits everyone involved and is therefore truly collaborative. Not having to charge users and therefore not putting a potential cost barrier to safety has been critical to its success in reducing damages; the key objective. Other countries have pushed a 'user pays' model that generates significant income but leads to a higher risk of significant costs elsewhere as users do not use the service every time they need to, which results in a higher risk of damages.

In terms of data, it has been achieved and developed without having to spend millions and spend years in the quest to have a common data format before any benefits are enjoyed. It is based on maximising the opportunities for interoperability for multiple stakeholders simply and effectively.

To build on this, improvements to data quality would allow better use of the data through further coordination and consistency, such as technological advances and innovation. This should be driven by the industry through a balanced representation of those that own the data and those that require it- something that has always been a challenge to achieve in industry groups that are predominantly made up of those organisations that require the data. The Geospatial Commission should, in our opinion, help facilitate that industry discussion and build on what has been successfully achieved so far.

Q5: Do you anticipate that any changes will be needed to the both address data and the wider address ecosystem, to support emerging technologies? Please provide evidence of value to support any proposed changes.

This is not an area we are qualified to comment on.

Q6: How should the commission be looking to develop the UK's capability in Earth observation data, both technologically and to support an effective market?

This is not an area we are qualified to comment on.

Q7. Which new technologies should the commission focus on to provide new opportunities to process and exploit geospatial data for economic growth?

Our feeling is that the most important challenge to solve is the improvement of data. Take care of that and the technology should take care of itself through private enterprise and competition.

Q8. How can geospatial data and applications be used to support enhanced roll-out of future technologies?

This is not an area we are qualified to comment on.

Q9: What are the options for how public sector organisations could continue to invest in maintaining and enhancing our geospatial data assets?

Our experience suggests that the public sector organisations (particularly local authorities) have been least interested in investing in their data to share it for the common good.

We would recommend that local authorities are supported to realise the data improvement benefits that private sector organisations have enjoyed.

Perhaps being encouraged to understand and follow best practice in how to manage their underground assets and evaluate how this could help those working in their areas on a day to day basis to increase productivity, drive economic growth and improve the delivery of public services (in particular utilities).

Q10: What areas of the underpinning geospatial infrastructure such as positioning technologies, including GPS and indoor positioning systems, and geodetic networks and frameworks to support them, should we be prioritising the development of, in order to support the emerging requirements for geospatial data?

This is not an area we are qualified to comment on.

Q11: What role should the private sector have in both the development and maintenance of the underpinning infrastructure and enhancing the UK's geospatial data assets?

For the last 15 years, we have provided a critical public service as a private organisation for the benefit of UK PLC. We believe as a private sector enterprise, we are well placed to understand the requirements of the market, are flexible enough to adapt to change and remain conscious of the responsibility of what we do.

We have been proud to help enhance the use of GB's utility infrastructure and geospatial information, used by private and public sector in relatively equal measure.

In providing 2.5 million searches every year, we know who wants buried asset data and how and when to communicate with them. Business flow lines are already established and safety critical work is well protected. We have established the infrastructure that underpins safe ground working in the UK and this mature and effective process will only be enhanced by the introduction of more and better underground asset data.

Q12. Do you face challenges when working with geospatial data from across the public sector? If so, what are they and how could value be better released? Are there any technical remedies or standards that could be adopted to improve the interoperability of geospatial data? Please provide supporting evidence of what these remedies could help to accomplish.

Our experience suggests that the public sector organisations (particularly local authorities) have been least interested in investing in their data to share it for the common good.

We would recommend that local authorities are better supported to realise the benefits that private sector organisations have enjoyed. Perhaps being encouraged to understand and follow best practice in how to manage their underground assets and evaluate how this could help those working in their areas on a day to day basis.

The data produced from the Utility Strike Avoidance Group's annual survey has consistently shown that the highest volume of strikes was on street lighting cables for every year from 2013 to 2016 which is linked to the lack of available data of their location.

Providing assistance to local authorities to accurately capture and digitise new assets (in accordance with PAS256) and existing assets would help reduce the risk of strikes and associated implications of human injury and other costly factors such as repairs and delays etc.

Q13. How can the Geospatial Commission act as a more effective customer for geospatial data on behalf of the public sector?

Our belief is that the Geospatial Commission's role is to provide an organisational view of the benefits available of using geospatial data most effectively. This should entail providing a high-level voice and opportunity to share best practice across the key public sector organisations.

Q14. Are there any additional geospatial datasets, from the other partner bodies or other sources, that the public sector would derive significant benefit from having access to, that might have novel and valuable use cases? What would that access look like?

As stated above, our service is available to all and is already well used by a wide range of private and public sector organisations. The assets registered are, however, predominantly private sector assets and adding key public sector asset data, such as local authority cables, pipes, culverts and any other relevant underground (or overhead) assets to the service would benefit all stakeholders to increase productivity, drive economic growth and improve the delivery of public services (in particular those utilities that we help protect).

Q15: How can we best develop a single UK strategy, ensuring alignment between the individual strategies across the UK while still allwoing for regional variations?

We operate across Great Britain and receive significant search volumes across all areas. This co-ordinated, cross boundary approach means that more people use our service, even in areas such as Scotland, where the Scottish Government's Roadworks Commissioner established a service that was meant to do what we do.

Through a bespoke and adaptable approach (rather than enforced and prescribed), our Members and Users use the service because it provides them both with tangible benefits and is therefore a concept that we would recommend for UK strategy. The industry needs to avoid Government driven projects that do not deliver what the industry needs; we suggest that the Geospatial Commission's strategy is best placed to truly understand industry and support successful initiatives rather than develop replacements that may be driven by a particular stakeholder's requirements.

Q16: How can we best ensure effective local authority coordination and sharing of best practise, using location data to better deliver public services?

As stated above, our service is available to all and is already well used by a wide range of large and small private and public sector organisations. The assets registered are, however, predominantly private sector assets and adding key public sector asset data, such as local authority cables, pipes, culverts and any other relevant underground (or overhead) assets to the service would benefit all stakeholders to increase productivity, drive economic growth and improve the delivery of public services (in particular the utilities that the service helps protect).

Q17: As a result of this analysis, we are prioritising the exploration of possible initiatives in the high-value categories identified:

- **property and land**
- **infrastructure and construction**
- **mobility**
- **natural resources**
- **sales and marketing**

What are the existing or potential geospatial applications which could be scaled-up or developed in order to capture economic value? (We would particularly welcome responses from industry and other bodies engaged in these sectors.)

As detailed above, the LSBUD service already provides significant value to those undertaking works. The key benefit and value creator is the avoidance of damage from utility strikes although at present there is not enough data to accurately measure the impact across all sectors.

The most measurable impact is the time saved by our users. In 2018, we will process over 2.5 million searches. For every search, each of our 72 Members is checked instantly. If LSBUD did not exist, the user would need to contact each Member individually which would take an average of 5 minutes per interaction. Accordingly, a single search would take 360 minutes or 6 hours which means that we provide a service that saves the UK 15 million man hours per annum. Furthermore, every new Member that joins the service provides approximately a saving of circa 200,000 man hours per annum.

It clearly shows the benefits for UK PLC, without any tax payer funding or support, whilst also saving the asset owners' time and cost.

The three categories that are particularly relevant are:

1. Property and land

Our service is used by landowners, residential occupiers and the legal profession for anything from erecting a new fence to completing legal deeds.

2. Infrastructure and construction

Our service registers pipeline and utility route information and is used daily to support its maintenance as well as the optimal route locations for new infrastructure to reduce planning times and maximise return on investment.

3. Mobility

The service is used to plan and inform roadworks, minimising disruption and reducing the impact of roadworks on the road users, therefore improving the area's productivity.

Q18: Are there any other areas that we should look at as a priority?

This is not an area we are qualified to comment on.

Q19: What are the main potential private and public sector innovations that will rely on the use of geospatial data to rollout, and are there corresponding regulatory challenges?

This is not an area we are qualified to comment on.

Q20: How best can we make the UK's presence in the international geospatial world more visible?

As stated above, we partnered with PelicanCorp, an Australian firm, in 2012/13 as they were supplying similar services (in our niche area of the industry) to several international regions. We assessed what was available across the World and partnered with the firm to be able to learn from international best practice.

We are developing our service on the back of this technology and can share how we have used it to the best possible outcome. We are the biggest single operator of such a service which means that we have more data than any other operator across the World. This means that we can develop opportunities such as predictive analytics quicker and more effectively than anywhere else in the World and lead the research as a result.

The Geospatial Commission could help by working with the regulators, including OFGEM, OFWAT, OFCOM, HSE and USAG, to support and encourage that better data is collected when damage incidents happen so that we all have better understanding of the causes why things have happened.

Q21: Where should the UK be looking for points of comparison overseas? Who are the other international exemplars? What best practice is being modelled overseas that we can learn from?

In accordance with the answer provided to Q20, with better damages data, we are able to benchmark our performance internationally, as part of a collective approach that has already started with organisations in the US, Canada, Australia and New Zealand. All the countries have elements of exemplary practice, whether it be cross sector industry compliance, membership or damage reporting. We would be happy to share our knowledge of international practices, following presence at international damage prevention conferences across the World, notably in the US and Australia where we discussed systems and models as well as regulator input and legislation.

Thank you for your time in completing your response to our call for evidence.

Any questions, please get in touch with the Geospatial Commission via geospatialcommission@cabinetoffice.gov.uk

Call for evidence - three key themes

We have identified three high-level themes that could help our approach to setting a strategy which are as follows:

1. **Supporting innovation in the geospatial sector**, exploring how to secure cutting edge skills, the right access to data, and opportunities from emerging technologies for the geospatial sector itself
2. **Enhancing the UK's geospatial assets,** looking at how best to align interests, avoid duplication, and instill best practice across the whole public sector
3. **Driving investment and productivity in geospatial applications**, asking in which wider sectors the most value lies from better exploitation and use of geospatial data, in the UK and internationally

Our questions

Q1. Is our view of the geospatial data types accurate? If not, what should be included or excluded from this?

There are a lot of datasets which include information on the natural environment which should also be included. These include but are not limited to
Wind speed
Rainfall amounts
River locations
Soil moisture defecit
SYNOP's
Location of historic landslides and other go-hazards

Q2. In addition to current government policy, what are the areas of geospatial skills where the commission could best focus, to help ensure the necessary capability within the UK for the future?

The creation of a standard file format for all geo-spatial data would be a welcome addition. This file format should be capable of being opened on freely available software (e.g. R or QGIS). In addition all data should be made freely available for use under a commercial licence. Although the government has taken steps in this direction by the introduction of the open government licence However, many datasets are still not available in an easy to use format.

e.g. The BGS location of historic landslides.

Q3. What are the geospatial skills needs and gaps in your organisations, how can these be most effectively addressed, and how can careers in the sector be best promoted?

Keeping up with what is and what is not available is a challenge. The creation of a database which only shows datasets that are currently available would be a welcome addition. Data.gov.uk often contains data sets which are not openly available.

Q4. Are there any publicly or privately-held geospatial datasets that are currently challenging to access or use or of insufficient quality, but which you or your organisation would find valuable if these issues could be resolved? Please explain why this would be of value, and how access/quality could be improved?

The source data contained within the BGS Geo-index. These are often presented as layers which can be downloaded for ARCGIS or Map info which are both proprietory pieces of software.Being able to accurately locate the position of landslides and the nearest postcode unit is of interest to us from an underwriting perspective.

A large number of datasets which are held by the Met Office require you to pay a large fee in order to access them. E.g. SYNOP data is only released in chunks based on a limited number of years and a limited number of stations. This makes it difficult to access, even though it is covered by the open overnment licence.

Weather data is extremely valuable to us in Underwriting both for evaluating the output from catastrophe risk models and for creating new models in order to challenge the assumptions of those produce by proprietory vedors.

Q5: Do you anticipate that any changes will be needed to the both address data and the wider address ecosystem, to support emerging technologies? Please provide evidence of value to support any proposed changes.

A standardised format to store all data types would release a large number of man hours expended in formatting each individual file format. This would also decrease the amount of time it would take to teach somebody to use such data.

Q6: How should the commission be looking to develop the UK's capability in Earth observation data, both technologically and to support an effective market?

Training needs to be provided at school level in how to access and open these data types. Including training in the practical application and the benefits that can be derived from these products would also be useful.

Q7. Which new technologies should the commission focus on to provide new opportunities to process and exploit geospatial data for economic growth?

Many datasets are not used in the insurance industry due to the high cost of licensing these. For example the BGS produce data sets relating to soil types and the risk derived from landslips.

It would be advantageous to the Underwriting team if the BGS were required to licence these data sets for just a temporary period in order for underwriters to prove that they are useful. This means that the BGS data set could be compared and contrasted against other data providers before purchase. This would, in my opinion, lead to a much better market for these datasets where the quality of the data set could be directly linked to the price charged.

Q8. How can geospatial data and applications be used to support enhanced roll-out of future technologies?

Currently the catastrophe risk market is dominated by a few large companies. These models are not validated in any academic journals which leads to a both insurers and reinsurers having to rely on the same model in order to price policies and contracts.

Allowing academics and smaller companies access to high resolution geo-spatial data sets will allow the independent development of catastrophe risk models which can be validated in the open academic literature. An unprecendented degree of competition will then flow into the market as this leads to the models becoming better and more robust.

Q9: What are the options for how public sector organisations could continue to invest in maintaining and enhancing our geospatial data assets?

Public sector organisations need to get together and agree on a standard data format for all of their geo-spatial datasets. When doing so they need to consider how each data set can be accessed by the widest number of possible users.

Q10: What areas of the underpinning geospatial infrastructure such as positioning technologies, including GPS and indoor positioning systems, and geodetic networks and frameworks to support them, should we be prioritising the development of, in order to support the emerging requirements for geospatial data?

The use of drone technology to provide increased resolution and detail on the spatial positioning of individual buildings would make a welcome addition. Information on the roof shapes would be particularly useful to catastrophe risk modellers.

Q11: What role should the private sector have in both the development and maintenance of the underpinning infrastructure and enhancing the UK's geospatial data assets?

The private sector will only co-operate if a clear profit can be realised from such technologies. By controlling any of the infra structure, private companies will be disincentivised to allow access to other members of the community. It needs to be the UK government which invests in the underlying infrastructure whilst allowing the private companies to profit thus increasing the GDP of the country.

Q12. Do you face challenges when working with geospatial data from across the public sector? If so, what are they and how could value be better released? Are there any technical remedies or standards that could be adopted to improve the interoperability of geospatial data? Please provide supporting evidence of what these remedies could help to accomplish.

N/A

Q13. How can the Geospatial Commission act as a more effective customer for geospatial data on behalf of the public sector?

Unknown.

Q14. Are there any additional geospatial datasets, from the other partner bodies or other sources, that the public sector would derive significant benefit from having access to, that might have novel and valuable use cases? What would that access look like?

Unknown

Q15: How can we best develop a single UK strategy, ensuring alignment between the individual strategies across the UK while still allwoing for regional variations?

A single UK body should be set up responsible for storing and configuring geo-sptial data into appropriate formats. Standardising not only the datasets but also the documentation that supports them is an important task so that the value from each dataset can be realesed with ease.

Q16: How can we best ensure effective local authority coordination and sharing of best practise, using location data to better deliver public services?

Again having a body set up to oversee the collation and standardisation of all uk geo spatial datasets would be helpful in standardising the way in which data is stored and shared.

Q17: As a result of this analysis, we are prioritising the exploration of possible initiatives in the high-value categories identified:

- **property and land**
- **infrastructure and construction**
- **mobility**
- **natural resources**
- **sales and marketing**

What are the existing or potential geospatial applications which could be scaled-up or developed in order to capture economic value? (We would particularly welcome responses from industry and other bodies engaged in these sectors.)

The development of catastrophe models is an important example of how geo spatial information can be used to good effect in the insurance industry.

Q18: Are there any other areas that we should look at as a priority?

Unknown

Q19: What are the main potential private and public sector innovations that will rely on the use of geospatial data to rollout, and are there corresponding regulatory challenges?

Unknown

Q20: How best can we make the UK's presence in the international geospatial world more visible?

By learning how to utilise geo-spatial data sets and create commercial products from them the UK will gain a technological advantage which it can then export to the rest of the world. As with all technologies it is a race to become the best, be known to produce the best products and have the ability to price them competatively.

Q21: Where should the UK be looking for points of comparison overseas? Who are the other international exemplars? What best practice is being modelled overseas that we can learn from?

The US NOAA catalogue is a good example of how weather modelling data can be accessed for free. ECMWF also provide a good service. For example if I want to download weather obsrvations I have to download these from a US government website. The same information would be likely to cost me quite a bit after paying the Met Office's processing fee.

The situation has got better in the UK over the last few years with the innovation of data.gov.uk but it is still too hard to track down relevant data sets.

Geospatial Commission: Call For Evidence Response Questionnaire

Please submit your completed questionnaire to:

geospatialcommission@cabinetoffice.gov.uk.

Clearly title your email *'Call for evidence response'*.

About you and your organisation

Name	[Text redacted]

Call for evidence - three key themes

We have identified three high-level themes that could help our approach to setting a strategy which are as follows:

1. **Supporting innovation in the geospatial sector**, exploring how to secure cutting edge skills, the right access to data, and opportunities from emerging technologies for the geospatial sector itself
2. **Enhancing the UK's geospatial assets,** looking at how best to align interests, avoid duplication, and instill best practice across the whole public sector
3. **Driving investment and productivity in geospatial applications**, asking in which wider sectors the most value lies from better exploitation and use of geospatial data, in the UK and internationally

Our questions

Q1. Is our view of the geospatial data types accurate? If not, what should be included or excluded from this?

From a Lloyd's market perspective, we suggest the following digital trends need to be included into the broader categories outlined in the call for evidence.

- Internet Of Things and 'Smart Cities' sensor data
- Mobile tracking / telematics
- Automated Identification System (AIS) ship tracking
- Earth observation (including hyper-spectral, high-resolution optical and high resolution Synthetic Aperture Radar (SAR)

These all have wider implications in the use of geospatial data for underwriting, pricing, disaster mitigationand catastrophe (natural or man-made) event response.

The introduction and further use of geo-temporal data is also a key future driver of value. For example, in the Marine and Energy classes of insurance business, where the majority of risks are in transit, or whose insured values can vary over time.

Further to this we believe that additional steps to open access to data further and to make data more interoperable will foster additional use of geospatial data within the UK insurance industry.

Furthermore, the certainty of the source e.g. definitive addressing / geocoding information) and versioning of data is key to that data being moved around the insurance markets in a more efficient, transparent and fluid manner.

Q2. In addition to current government policy, what are the areas of geospatial skills where the commission could best focus, to help ensure the necessary capability within the UK for the future?

Lloyd's is the world's leading specialty insurance and reinsurance marketplace, which insures risks across a wide range of classes, including property, marine and energy, speciality and liability. The majority of these risks have a spatial context of some kind, either through location of assets being insured, or through being exposed to geographically explicit perils or 'shocks' such as natural catastrophe, geo-political, economic, or environmental disasters.

The LMA's members, who represent the Lloyd's community of managing agents, consume geospatial data in many formats, both in raw forms, but also in derived analytical outputs. This cuts across every activity and function supporting insurance business, including underwriting, pricing, exposure management, claims management, capital provision and regulatory oversight. Increasingly, geospatial data underpins critical analytical functions, especially within the fields of risk management, catastrophe modelling and event response.

Greater knowledge transfer and understanding of data is a key requirement for the Lloyd's market. This is required to ensure that exposure data and supporting information supplied to insurance companies is both appropriate and timely. This would focus not just on technical specialists but also (and more critically) on decision makers on how they use, interpret geospatial data and derived information.

The UK geospatial community could provide greater input to the professional qualifications required by insurers, for example the Chartered Insurance Institute, but also via market-specific career development programmes such as the LMA Academy (https://www.lmalloyds.com/academy). This should be tailored to each level of required technical understanding, and to the needs of each functional discipline, such as claims management. Equally, the Lloyd's market can provide reciprocal insight into the types of products and services which are most relevant to insurers.

In particular, the growth in the use of remotely sensed data, whether via satellite, drone or ground collection, is an area where greater knowledge transfer is required, between technical experts and providers, and the insurance community. For example, the recent LMA / Lloyd's initiative to provide centralised post-disaster Impact assessments via remotely sensed earth observation data has enabled all LMA members to access not only raw earth observation data, but also interpreted damage assessment reports and data via specialist image interpreters.

In addition, skills and services related to the Internet of Things, geo-temporal data (for example marine shipping and cargo), plus demographic and other population and Market data into Artificial Intelligence or other high performance analytics will be a key area for the Lloyd's marketplace in the near future.

While this is a UK focussed request for evidence, our business is worldwide, and we believe that this is a great opportunity to develop UK-based geospatial skills and knowledge which can be applied to global risk issues, and benefit the UK's leading position in an increasingly competitive global insurance market.

Q3. What are the geospatial skills needs and gaps in your organisations, how can these be most effectively addressed, and how can careers in the sector be best promoted?

We see the following skills needs and gaps from a Lloyd's market perspective:

- Contextualised / application-based training that is fit for purpose
- Interpretation of Earth Observation (Remote Sensing) imagery, full understanding of limitations and uncertainties by sensor.
- GIS is widely used in its simple form, e.g. Google Earth, simple overlays, map creation, and there are some companies who have invested in more sophisticated geospatial capabilities, for example setting up GIS teams and in R&D capability, but the industry does not consistently apply spatial analysis and inference techniques on a day-to-day basis.
- General use of GIS for spatial analysis, mapping, information products etc. And GIS systems often available in companies to some extent, e.g. MapInfo, ESRI, QGIS, SQL but lack of skills and understanding result in it hardly being used beyond simple operations
- Raise awareness of open geospatial datasets to complement commercially available datasets
- GIS needs to be more integrated in the day to day operations of modellers and underwriters, and to understand how spatial data can support decision making etc.

There should also be a focus on the positive impact that GI/Earth Observation can make to the Lloyd's market. This should be independent of the means required to deliver it – focus on "what" geospatial / Earth Observation can do for different insurance processes and the "how" can then follow.

Greater integration of geospatial capability into risk models, particularly catastrophe models, would also be of particular benefit, especially in relation to open source models such as the OASIS Loss Modelling Framework (https://oasislmf.org/), to improve calibration and validation of model outputs.

Q4. Are there any publicly or privately-held geospatial datasets that are currently challenging to access or use or of insufficient quality, but which you or your organisation would find valuable if these issues could be resolved? Please explain why this would be of value, and how access/quality could be improved?

From a Lloyd's market perspective, this is a global challenge, and the quality of available data can provide a significant limitation to the confidence which may be placed in the information and analytics applied to assess risk. In particular, the quality of location references, including geocoding and property databases, can be poor or incomplete. Improved access to 'authoritative' cadastre, asset registers, or other higher resolution data to locate risks more accurately, will improve the granularity and confidence in model outputs.

Access to public asset data, including infrastructure, would also be of great benefit in improving risk assessment confidence.

With respect to access to data, there are moves in the Disaster Risk Reduction/Insurance world to build portals providing access to free/commercial data e.g. Oasis Hub (https://oasishub.com/). It would be beneficial to see government interacting more with these entities to collaborate and provide input into them sharing best practice around usable open standards for geospatial data access. In particular, the Insurance Development Forum (IDF)'s current work on developing exposure data standards is one where there is the potential for government interaction.

Specifically, around property information there is a need for high resolution data needed, from a variety of sources including census, valuation office, all linked via unique address identifiers, ideally open access for use in commercial activities. Use cases include exposure enrichment, exposure development, insurance risk pricing, automated insurance placements etc.

As part of government and the engineering sectors thinking about Smart Cities and Building Information Modelling, there is a need to consider the geospatial assets behind these themes and how insurance can play a role in the life-cycle

management of buildings. Purely from a geospatial data point of view there is a need for more accurate 3D building data and underground assets data

Further, the Insurance Development Forum (IDF) is actively discussing open standards around exposure data schemas, which are essentially underpinned by geographical data. There is potential for geospatial data standards (e.g Open Geospatial Consortium) to feed into creation of exposure data standards.

Q5: Do you anticipate that any changes will be needed to the both address data and the wider address ecosystem, to support emerging technologies? Please provide evidence of value to support any proposed changes.

We feel there is benefit to incorporate the FinTech/InsurTech communities and how they are using address information to build faster and more efficient processes. There are many themes to consider:

- Links to other thematic data, e.g. census, to enable data enrichment processes, data accuracy assessment (e.g. for catastrophe modelling primary characteristics such as occupancy, building height, age and construction and other building information modifiers)
- Managing customer data, identifying customer behaviours, interactions and preferences, segmentation, customer support, personalised marketing, customer lifetime value, i.e. how much value will a business derive from their entire relationship with a customer, recommendation engines – this is applicable across many private sectors, also thinking automated insurance risk placing etc.
- Effective risk modelling, through improved accuracy and more information, and therefore better data-driven decisions. We can see this flowing through many areas of re/insurance business, not just natural catastrophe, but underwriting risks in general
- Real-time and predictive analytics, e.g. responding to risk event, e.g. natural catastrophes, cyber events, etc.
- Internet of Things and the subject of connectedness – with implications for cyber security but also to buildings and other physical assets.

Q6: How should the commission be looking to develop the UK's capability in Earth observation data, both technologically and to support an effective market?

The Lloyd's market is making increasing use of earth observation data across a range of activities. For example, the recent Lloyd's and LMA initiative to provide centralised post-event data and intelligence services, primarily for claims management, has been well-received in the marketplace. Specifically, the ability to quickly obtain this data, enabling an early assessment and immediate claims settlement post an event, which is a target of Lloyd's and the individual Managing Agents. Recent LMA events have highlighted the growing, but largely latent, value of earth observation data to support insurance risk assessment. In particular: more focus is needed on information which the insurance sector will use rather than raw data outputs which need further interpretation by experts (who may not be employed by an insurer).

Insurers would be more willing to subscribe to these information services which are targeted to specific problem spaces. Work has been done by independent bodies such as PERILS (https://www.perils.org/) to allow access to exposure and loss information across the UK and Europe. This could be expanded to common access to geospatial information products with the backing of governments as a data source/aggregator.

Other examples can be found from the development world, World Bank, United Nations and the Sendai Framework. For example, the Group on Earth Information (GEO) is working to improve availability, access & use of EO data (with 105 members world-wide), e.g. Geo Darma provides data access for Risk Management. The focus is on sustained end-to-end solutions.

Added to this, there is a need to raise awareness of professional accreditation, again, via bespoke career development activities.

Q7. Which new technologies should the commission focus on to provide new opportunities to process and exploit geospatial data for economic growth?

From an earth observation perspective, micro-satellite SAR constellations with multi-band and polarity would be a priority allowing very high temporal revisit frequencies, especially to capture rapidly developing events, such as flood. These have applications as far reaching as event response, claims analysis and parametric insurance for agriculture.

A focus on insurance technology (Insurtech) would be useful – to learn what small start-ups are doing in this space with many using geospatial techniques and accessing geographic datasets. Many start-ups are also developing exposure datasets on a global basis. There is a need for knowledge transfer between the start-ups and geospatial commission to look at best practice, standards, training and education around the use of geospatial in insurtech.

There is also the need to bridge the gap to geospatial non-experts who may use spreadsheets, databases and data visualisation tools but not have a much-needed awareness of the spatial components to data and information.

Q8. How can geospatial data and applications be used to support enhanced roll-out of future technologies?

The Lloyd's market is a leading supporter of innovative data and analytics products for insurance. The first cohort of Lloyd's Lab startups and InsurTech entrepreneurs will, in many cases, make use of spatially reference data to drive their products and services. This is very likely to be the case for those which follow. An increased awareness of the types of data being made available is therefore key, and improved understanding of the geospatial community to the specific needs of insurers for data and tools to support disruptive technologies and products would also be of great benefit.

Greater collaboration, mutual understanding and identification of opportunities, will only benefit both the UK insurance and geospatial sectors.

Q9: What are the options for how public sector organisations could continue to invest in maintaining and enhancing our geospatial data assets?

By supporting sectors such as insurance with a consolidated set of geospatial assets this would lead to efficiency gains and an increase in the use of geospatial data. Through public sector investment there are a wealth of reciprocal benefits which can come back to public sector from private industry. For example, though value added data, additional insights etc., as well as societal benefits in the form of better and cheaper access to insurance products, and in relation to contract certainty, which aims to better protect insurance customers.

Q10: What areas of the underpinning geospatial infrastructure such as positioning technologies, including GPS and indoor positioning systems, and geodetic networks and frameworks to support them, should we be prioritising

the development of, in order to support the emerging requirements for geospatial data?

Access to high resolution GPS is increasingly critical across all areas of geospatial data provision in our industry. We need to retain -UK's access to high precision and guaranteed GPS, and to monitor at how future higher precision GPS location data could be used to develop new and innovative insurance products. We also need to exploit as much as possible, smart IoT data, and human sensor capabilities. There is a link to disaster risk reduction and humanitarian response and how data collected on the ground in a disaster-prone or affected area can be used to help calibrate, augment and improve assumptions relating to risk modelling and resilience.

The Lloyd's market is a key supporter of Disaster Risk Financing (DRF) insurance, and can provide a valuable source of knowledge and insight to geospatial data providers when they are developing products and tools to support these activities around the world.

There should be more awareness of social media and individual people-sensors and how to engage and integrate personally collected data to improve for instance, catastrophe model vulnerability / exposure assumptions. The effective utilisation of social media and other 'real time' data sources will become increasingly important, particularly in respect to parametric insurance products where accurate data is required to validate the 'trigger' mechanisms which can initiate payout against particular types of events, but requires careful assessment and product design to ensure it is appropriate and be beneficial to insurance risk assessment.

Q11: What role should the private sector have in both the development and maintenance of the underpinning infrastructure and enhancing the UK's geospatial data assets?

The LMA is a collaborative organisation, and we would suggest that there should be a wider alignment of the geospatial community, and Lloyd's market members via LMA activities and groups. This could work on a range of issues and opportunities, including knowledge transfer, data standards, product and systems design and development, and product innovation. In addition, the role of Lloyd's Lab and InsurTech groups will be critical going forwards.

Q12. Do you face challenges when working with geospatial data from across the public sector? If so, what are they and how could value be better released? Are there any technical remedies or standards that could be adopted to improve the interoperability of geospatial data? Please provide supporting evidence of what these remedies could help to accomplish.

The main challenge is being able to identify and assess use of the data which may be available. The lack of centralised repositories or portals, to enable easy and controlled accessibility to data and other products, limits the use of these data by the market. Again, data standards are increasingly important in the insurance marketplace – recent initiatives to develop improved exposure data standards would benefit from greater input from the geospatial community. Increased interaction / collaboration between the geospatial community and the insurance market, via existing, or potentially, new forums, would be of great value.

In addition, costs of data can also be a barrier to use, especially in respect to detailed data, which can have prohibitive licencing costs, or restricted access. In terms of interoperability, the Lloyd's market is a major promoter of the OASIS Loss Modelling Framework, and this should be considered as a potential collaborative resource for improving the integration of geospatial data into insurance risk functionality.

Q13. How can the Geospatial Commission act as a more effective customer for geospatial data on behalf of the public sector?

From a private sector perspective, making sure it represents the needs of the end user communities and provides that central, proactive, centralised source whilst engaging with learned societies and organisations that try to help bridge the gaps e.g. UK innovate, Satellite catapults, Natural Environment Research Council etc.

The Geospatial Commission could act as a 'stamp of approval' for data sets, ensuring fitness for purpose and adequacy for the specific tasks required.In addition, as a promoter of the use of geospatial data within the insurance and reinsurance industries, in collaboration with the professional bodies, and potentially helping to lower barriers to entry, cost and expertise.

Q14. Are there any additional geospatial datasets, from the other partner bodies or other sources, that the public sector would derive significant benefit from having access to, that might have novel and valuable use cases? What would that access look like?

As previously noted, the Lloyd's market is an active and growing user of geospatial data and derived products, across many areas. The continually evolving, and diverse universe of risks which the market insures, means that is almost impossible to define what sort of datasets might be more or less useful into the future. However, the trend for increased risk assessment granularity, 'near real time' event monitoring, and understanding of complex and inter-dependent risk systems, means that the market's demand for data will undoubtably increase, and rapidly.

We would however, highlight the following as key areas for access to geospatial data:

- Geocoding and address location data
- Detailed population and geodemographic data
- High resolution (both spatial and temporal) earth observation data, especially SAR, which can improve event assessment
- Property valuation data
- Greater access to government data including infrastructure, crime, traffic accident and other incident data
- Telematics data, port inventories and other time varying data

.

Q15: How can we best develop a single UK strategy, ensuring alignment between the individual strategies across the UK while still allwoing for regional variations?

There should be greater alignment between the strategic direction of the Lloyd's market, and its members, and the overall strategy for geospatial data, both in terms of data acquisition as well as data products. The Commission may be a forum for developing these links.

Q16: How can we best ensure effective local authority coordination and sharing of best practise, using location data to better deliver public services?

The LMA would not see this is a major concern, but more generally, data standards and the need for collaborative data sharing continues to critical to improved application of geospatial data in our industry.

Q17: As a result of this analysis, we are prioritising the exploration of possible initiatives in the high-value categories identified:

- **property and land**
- **infrastructure and construction**
- **mobility**
- **natural resources**
- **sales and marketing**

What are the existing or potential geospatial applications which could be scaled-up or developed in order to capture economic value? (We would particularly welcome responses from industry and other bodies engaged in these sectors.)

The insurance industry and Lloyd's market in particular, will have interest in all the above. Some evidence use cases would be helpful. The call for evidence document has listed insurance pricing and the Geospatial Commission should also consider disaster response, claims management, customer-centric insurance solutions, new insurance products through smart home technology to lower premiums and insurance costs, risk management and transfer of solutions, data and analytics to identify new solution to bridge capital with new & emerging risks. The insurance sector body could be the liaison between the commission and the insurance industry to look at collaborative efforts to build partnerships.

Q18: Are there any other areas that we should look at as a priority?

As noted above, the insurance industry makes use of geospatial data across many functional areas, including underwriting, claims, modelling and analytics. There should be a focus on the use of geospatial within insurance and the work done from within the insurance industry to contribute to resilience in the face of climate change. Work done by the IDF (theidf.org) and others in the industry has a large geospatial component and should be investigated by the Geospatial Commission.

Q19: What are the main potential private and public sector innovations that will rely on the use of geospatial data to rollout, and are there corresponding regulatory challenges?

Insurtech should be the focus plus rapid response EO / sensor data. There are potential challenges from financial and insurance regulators, especially when relating to capital management, new insurance products etc. where the use of geospatial data and technologies underpin the modelling behind the solutions.

Another policy issue to consider is GDPR in terms of how data is used, shared and individuals knowing about this. Data privacy is a concern.

Q20: How best can we make the UK's presence in the international geospatial world more visible?

As noted, the LMA represents an industry sector which operates across global insurance markets. The role of UK geospatial expertise in the provision of the acquisition systems, platforms, tools and data products is significant, and this aligns well with the world leading position of the UK insurance industry. In particular we highlight the following areas where a relationship between the insurance industry, including in the Lloyd's market, and the geospatial community, could further develop influence and visibility:

- Investing in high resolution spatial and temporal EO, especially SAR and hyperspectral capabilities.
- Developing capabilities for insurtech exploitation of spatial data, which can be used both in the UK and internationally
- Developing human sensor capabilities to improve risk assessments and

claims analysis

- Leading centralised data services for multi-sector use
- Leading in applied research, and journals and publications
- Leading in product innovation
- Leading in data access, best practices
- Focussing on public relations: sharing of success stories, visibility to the public, launch a campaign to raise public awareness, link with themes that are important to the common person (how is this relevant to someone you stop on the street?)
- Promoting and making available more open (free) data which will drive wider innovation and commercial use
- Investing in engaging with the industry to gain a sense of the possible and what is needed to get there

Q21: Where should the UK be looking for points of comparison overseas? Who are the other international exemplars? What best practice is being modelled overseas that we can learn from?

We believe the following international organisations could be looked upon to provide exemplars of best practice:

- World Bank, UN, Red Cross – all innovators in the use of geospatial data.
- ESA and Copernicus and the Disaster Charter
- Open Geospatial Consortium
- US Government data sourcing
- JRC and EU-wide, cross country initiatives such as EFAS (European Flood Awareness System)

The use of geospatial data in the insurance sector could also be discussed in forums such as UN-GGIM to discuss overlaps with disaster risk reduction and climate change initiatives.

Thank you for your time in completing your response to our call for evidence.

Any questions, please get in touch with the Geospatial Commission via geospatialcommission@cabinetoffice.gov.uk

About Location International Ltd

Location International Ltd provides strategic advice and full operational capacity globally, to the public and private sector, as to how to gain from improving their own use of location information to enhance their decision-making and to meet the ever-changing needs of their customers and stakeholders.

Call for evidence - three key themes

We have identified three high-level themes that could help our approach to setting a strategy which are as follows:

1. **Supporting innovation in the geospatial sector**, exploring how to secure cutting edge skills, the right access to data, and opportunities from emerging technologies for the geospatial sector itself
2. **Enhancing the UK's geospatial assets,** looking at how best to align interests, avoid duplication, and instill best practice across the whole public sector
3. **Driving investment and productivity in geospatial applications**, asking in which wider sectors the most value lies from better exploitation and use of geospatial data, in the UK and internationally

Our questions

Q1. Is our view of the geospatial data types accurate? If not, what should be included or excluded from this?

The definition of geospatial data given would not be instantly recognisable globally.

The collection of 1-4 could be renamed as 'geospatial information' and 1 and 3 could remain as written. Globally the term 'positional data' used in 2, normally refers to data collected by GNSS or to GPS data. It is clear that is not what is termed here and so perhaps the definition should be renamed to avoid confusion with the global norm. This has been named in the past as 'geospatial exhaust data' or 'secondary geospatial data'. The term Geospatial Services used in 4 should perhaps be more reflective of the industry and could be "geospatial intelligence products and services".

A broader definition for geospatial might be agreed by the Commission. One of the major issues holding back the global geospatial community is a lack of understanding by everyone else, of the term 'geospatial'! For a written piece for a Global South audience in June 2018 I defined it as follows:

"The term Geospatial encompasses both earth observation using satellites and other remote vehicles and those activities in data analytics using statistical and geographical frameworks, embracing all the new ways of analysis of the associated data, including those undertaken by machine learning and deep learning.

The resulting geospatial information outputs enable improved decision-making in both the public and private sectors and in both the developed world and the global

south, leading to better performance and improved use of resources. Good examples can be found in all economic sectors, including health provision, government, transport, financial services, agriculture, construction and in innovative new services; all of which contribute to both improvements in operational efficiency and wealth creation."

Q2. In addition to current government policy, what are the areas of geospatial skills where the commission could best focus, to help ensure the necessary capability within the UK for the future?

The Commision should focus on capacity building. There is an ever increasing demand for 'capacity building' globally following the rapid global growth of the use of geospatial information. The lack of well-trained professional and technical people in the area is one of the major factors limiting the growth of the sector world-wide.

There is a requirement for training that is not focused simply on the 'buttonology' of vendor courses where the emphasis is specifically aligned to operating specific items of hardware and software; but instead on developing a greater understanding of the subject areas.

Outside of this training, geospatial skills development currently takes place in three areas in the UK:

1. Masters courses in GIS; feedback shows that many of these courses do not give the modern grounding needed by the majority of employers as they are not focussed on the computer development software skills but more on the computer vendor package operator skills. As more users move to open source software useage this grounding is inadequate.

2. Geospatial apprenticeships: These have commenced https://www.tsa-uk.org.uk/government-gives-go-ahead-geospatial-apprenticeships/ but little publicity has been given to them and once again early feedback shows people are more likely to accept an apprenticeship in a mainstream subject such as Engineering rather than geospatial as it is thought the future job opportunities are greater.

3. On the job training: The majority of this is taking place in the public or third sector. Due to the skills shortage, it is being reported that as soon as someone is trained, they move onto a better paid role in the private sector.

Geospatial analysis is used in many subjects at University (e.g. Engineering, Geography, Planning, Health Care, Archaelogy to name a few) as can be evidenced by the huge useage of geospatial data supplied by the JISC contract. Geospatial skills need to be taught today as a basic skill to all those entering

Higher Education but it is necessary for Data Scientists and general Computer Scientists to have geospatial modules built into their curriculum as they are in other countries. This will promote a reduction in the level of expensive, difficult to recruit specialist skills and expertise needed in the end-user community which is currently preventing geospatial becoming universally adopted as it will mainstream the subject area into IT.

It is pleasing to see that 'Geography' is now a profession within Government and this will give those involved a platform to improve the awareness of the importance of geospatial in their departments and agencies.

Q3. What are the geospatial skills needs and gaps in your organisations, how can these be most effectively addressed, and how can careers in the sector be best promoted?

Careers in the sector can be better promoted by better communication skills being available within the industry, modern supporting material being available about the use of geospatial and a better understanding that 'everything happens somewhere'.

Most organisations wishing to use geospatial effectively in a professional production environment require software engineers with geospatial data analysis skills and relevant domain knowledge as described in Q2.

Key skill requirements include:

- Geospatial strategists – very few exist and hence too many times discussions involving geospatial work is reduced to technical, non-strategic discussions
- Experts in big data analytics and the application of machine learning and artificial intelligence to geospatial data and in particular earth observation data.
- Developers and software architects with geospatial data processing and applications development expertise
- Geospatial project managers

Q4. Are there any publicly or privately-held geospatial datasets that are currently challenging to access or use or of insufficient quality, but which you or your organisation would find valuable if these issues could be resolved? Please explain why this would be of value, and how access/quality could be improved?

It would be helpful to have a freely available cross-reference table between all the common identifiers that relate to 'place' used in government e.g. UPRN, USRN, TOID etc.

It would be helpful for the UK to decide upon the national geospatial data stack

and ensure that each of those datasets are fully able to be maintained to the desired quality, to be licensed in a uniform way and accessed by both the public and the private sector for reuse. This is the norm in many countries and is known to drive economic efficiencies for both the public and the private sectors.

It would also be helpful if there was a national geoportal; this also is the norm in many countries and facilitates data being collected once by the public sector (and their contractors) and reused many times. This does require though a more mandated use of Open Standards based on the published ISO geographic standards and the published OGC standards.

Finally, much emphasis to date by the Commission has been given to making OS MasterMap an open dataset. This is an unusual choice by global norms as most countries have no equivalent. As most users now look for global exemplars when making investment choices, the current emphasis is surprising as it will be very complicated to manipulate and most users who are innovating new applications will not have the capacity to deal with the complexity of the data structure.

In most countries, the key reference geography that people wish to have 'open' as it gives greatest commercial and public good value is:
a. a regularly updated stream of earth observation data derived from satellites, HAPS or aerial collection
b. a comprehensive and maintained address dataset if it exists or a proxy for this dataset
c. a hazards dataset to assist universal use and awareness by the nation in preparation and during hazard events e.g. flood events

Q5: Do you anticipate that any changes will be needed to both address data and the wider address ecosystem, to support emerging technologies? Please provide evidence of value to support any proposed changes.

A revision of the Address Standard BS 766 would be timely with reference to work being undertaken in ISO TC 211 to support emerging technologies and also to take feeds from third parties.

Q6: How should the commission be looking to develop the UK's capability in Earth observation data, both technologically and to support an effective market?

The UK is already known globally as a leader in Earth Observation and has been for the last 40 years. We must ensure we embrace all the new technologies ensuring we develop suitable government policies with industry for the use of not only Satellite data but also HAPS, drones and aerial imagery. Over the last 10 years, the Daily Mail newspaper has run stories about 'spies in the sky' and has created negative public reaction to these new technologies being used by government. Most countries have a definitive published policy and to date this has never been in place in the UK. Today one cannot stop anyone or any country looking at anything and it is important that with this knowledge, the policy is developed and published.

A key role for the Commission would be to organise and coordinate the UK government's needs for geospatial information – essentially acting as 'intelligent customer' for geospatial information services on behalf of the UK public sector and extending this agreement, if possible, to the third sector. This is already enabled for some key datasets but it should be extended so that the Commission is the 'central procurement hub' that can articulate clearly their needs.

It is well known that Great Britain is a leader in the production of geospatial data from the six named agencies mentioned in the Consultation. Interestingly, we have many national and non-national suppliers of aerial imagery and no national suppliers for satellite earth observation imagery. This situation is globally unusual. There is normally much more 'national control' over aerial imagery companies either by ensuring they are nationally owned or by ensuring that certain national personnel must be on board in the planes when imagery is being collected.

With the development of HAPs, the exponential increase in the collection of high-resolution satellite data, these 'national controls' are becoming worthless. However, many nations are now choosing to invest in their own national capacity for HAPs and Earth Observation satellites so they can control their output both over their own nation[1] and what they choose to view over other nations. This is something the Commission should consider co-ordinating for the UK.

Q7. Which new technologies should the commission focus on to provide new opportunities to process and exploit geospatial data for economic growth?

Artificial Intelligence and Machine learning are becoming central to the

[1] Due to cloud cover only radar earth observation satellites will be of use over the UK

exploitation of geospatial data in the most advanced economies. Currently in the UK, a few SME companies have been working to develop training datasets for Machine Learning but as Geospatial is not seen as a priority of the nation, unlike nations in the Far East, we are not growing as rapidly in this arena - despite as a country being one of the leaders in this technology via DeepMind and others in this sector.

The relationship between 5G, smart places and geospatial should not be overlooked and hence a focus being given by the Commission to artificial intelligence, machine learning and 5G in the sector would be most helpful and will accelerate the use of geospatial in many areas. It is also likely to unlock certain industries that in this country have not yet entirely embraced geospatial data analytics such as the financial services sector.

Q8. How can geospatial data and applications be used to support enhanced roll-out of future technologies?

To support enhanced roll-out of future technologies, it is essential to improve the awareness of the power of the use of geospatial and how it is an underpinning co-ordinating infrastructure (sometimes illustrated as the backbone) of any new data driven technological environment.

It is currently deployed in 'silos' in the UK unlike some other countries and so one can see excellent use of it being made in transport, agriculture, health, energy etc. but its use is not universal mainly due to the lack of awareness and the human capacity issues already mentioned.

Having improved awareness, accessibility to geospatial data is a vital component and hence a national portal is vital. This should not be a repository of 'all data' but just a light touch wrapper that connects to Departments and Agencies to return to the customer either the service or product they require instantaneously.

All data collected in the future needs to be:

- Fully interoperable and hence mandating the use of international Standards in each future procurement of geospatial data by the public sector will improve the ability for data to be reused and repurposed to support future technologies.
- At the same time, the intellectual property rights management in the acquisition of geospatial data is a vital skill that must be understood by those in the public sector geospatial community whose duty it is to acquire datasets for the public sector.

Universal national usage of geospatial is something many countries are achieving or plan to achieve within the next 36 months. It is surprising that the UK is the home of some of the best data in the world but yet due to historical reasons, geospatial data has never managed to be viewed as being an essential

part of the UK infrastructure. Hopefully the work of the Commission will now achieve this and hence geospatial data and applications will assist the adoption of future technologies.

Q9: What are the options for how public sector organisations could continue to invest in maintaining and enhancing our geospatial data assets?

Many public sector organisations collect data; some undertake the collection as their main task and for others it is a by-product of another aspect of their work.

It would be helpful if the Commission could relook at the national need for geospatial data so that the nation has like other countries a comprehensive underpinning geospatial infrastructure framework. Hence instead of these datasets being 'producer led', they become 'customer led'. This would then assist the Commission to:

1. Define what are the essential datasets for the nation that must conform to international standards for interoperability and accessibility
2. Define the specification of the geospatial portal and which datasets are within it and those that are not
3. Define the future maintenance regime for each dataset and be clear as to the acceptable quality standard for each dataset.
4. Define the annual financial investment needed for each dataset which can either be invested by the organisation in return for a revenue opportunity or invested by government so that it can be free of charge at point of use. The key aspect that must be considered is 'someone has to define the specification and then financially pay to maintain currency and maintain quality'. Unmaintained data quickly reduces in value to everyone.

Many public sector organisations in the UK invest in maintaining their own geospatial data sets. This is a rare business model around the world; many equivalent organisation now act more like a regulator as they only:
1. create the conditions for data to be collected
2. define the acceptable quality of a dataset for the nation
3. monitor a private sector contractor to collect the data using ISO 19157 that establishes the principles for describing the quality of geographic data. It

- defines components for describing data quality;
- specifies components and content structure of a register for data quality measures;
- describes general procedures for evaluating the quality of geographic data;

- establishes principles for reporting data quality.
- defines a set of data quality measures for use in evaluating and reporting data quality.

Q10: What areas of the underpinning geospatial infrastructure such as positioning technologies, including GPS and indoor positioning systems, and geodetic networks and frameworks to support them, should we be prioritising the development of, in order to support the emerging requirements for geospatial data?

Access to high integrity and high precision GPS/GNSS signals is an essential part of a modern economy and can be seen to take considerable cost out of many essential industries of nations.

Ordnance Survey like many other similar organisations around the globe has developed a well-maintained geodetic network called OS Net. Unlike many others though they have managed to run it as a 'managed service' for many years so ensuring that the investment in the equipment can be maintained. However, despite OS Net being an essential backbone for its own activities and also the activities of the emergency services, it is under utilised by other sectors. It is a national asset and should be invested in further to increase its cyber resilience and general capacity and promoted as an essential part of the national infrastructure that should be reused universally by the construction industry and others needing accurate positioning in their daily occupations.

Indoor positioning technologies is becoming the norm in many countries but I cannot think of any that have been 'government sponsored'. This work tends to be led by private sector companies who wish to 'sell services and augmented reality experiences' once inside a building.

The other aspect that should be considered is the role of the Commission in the buried services/underground assets community. This is an area that most governments intervene and it is very much normally a government-led area to ensure that overtime the underground assets become better organised than over previous decades. In the UK, the work has been led by NJUG http://streetworks.org.uk but as a Trade Association they perhaps should have an affiliation with the Commission in the future.

Q11: What role should the private sector have in both the development and maintenance of the underpinning infrastructure and enhancing the UK's geospatial data assets?

The private sector clearly often articulates that they would like to provide more services to the public sector; but with that comes the added responsibility for maintaining the nation's infrastructure or providing services to it.

To date there has been insufficient investment by the UK owned private sector geospatial companies for them to actually be significantly large companies to take on such a responsibility and hence the overseas private sector companies often benefit.

Naturally the argument can be made that procuring from the private sector would encourage further private sector investment for the benefit of all but to date lenders have been reticent to invest as once again the lack of awareness of the power of geospatial has meant they are more likely to invest in more mainstream technology companies; hence most UK-owned geospatial companies have turnovers of less than £10M per annum.

Many nations think about creating such entities from their own public sector companies and making them Government Owned companies with a plan to eventually grow other business outside their own nation's responsibilities.

To date though there are no example success stories globally for countries that have tried this to date. Failure has occurred as the entity that becomes a GovCo, which is outstanding at creating, and maintaining the nation's geospatial data does not have the culture in the operational staff to become agile enough to attract other substantial business. In the cases that have tried this business model, management have been keen but it has been the operational staff who are the 'heart and lungs of the organisation' that have been unable to make the transition.

Q12. Do you face challenges when working with geospatial data from across the public sector? If so, what are they and how could value be better released? Are there any technical remedies or standards that could be adopted to improve the interoperability of geospatial data? Please provide supporting evidence of what these remedies could help to accomplish.

Geospatial data from across the public sector should comply to the EU INSPIRE guidelines. Even though the UK is leaving the EU, it would be a most unusual decision for the UK to abandon these guidelines as nearly 90 countries around the globe have adopted them as 'best practice' even though they are only mandatory via the EU Directive to the EU nations. By complying to INSPIRE guidelines, one authomatically is adopting 'best practice' for:

- the interoperability of datasets
- the accessibility of datasets
- the use of international standards (ISO, International Hydrographic Organisation (IHO) and OGC standards)

A single accessible 'light touch' portal for UK government geospatial data as mentioned earlier with e-licensing in place would increase the useage of the data and reduce the burden on all users from the public and private sector to access the geospatial data.

Q13. How can the Geospatial Commission act as a more effective customer for geospatial data on behalf of the public sector?

The Geospatial Commission can act as a more effective customer for geospatial data on behalf of the public sector by:

- identifying areas of duplication or overlap, so that relevant geospatial data can be acquired once by government and used multiple times. This is a problem for all governments until they look at their geospatial data in a holistic way – a recent example being one country with 14 different government departments collecting the coastline of their country to 14 different sets of guidelines; resulting in 14 different versions being in existence, 14 teams of people duplicating work and 14 IT infrastructures being maintained.
- being the procurement hub for geospatial for the pubic sector and possibly the third sector
- helping to frame the final requirement for certain datasets e.g. for height data, what is required - is it the height of land, average height of building, height of roof line etc.
- improving the understanding of the use of geospatial in the public sector and the private sector too
- differentiating the geospatial sector from the 'big data economy' but ensuring it is seen as an essential element of this economy
- being transparent to industry, such that industry can work with government to plan its own development and associated investment
- ensuring there is sufficient diversity in the requirements that both medium and large companies can tender rather than the medium sized companies always having to work through a large company which can jeopardise their growth

Q14. Are there any additional geospatial datasets, from the other partner bodies or other sources, that the public sector would derive significant

benefit from having access to, that might have novel and valuable use cases? What would that access look like?

This is a tough question to answer unless one has thought through the need and also how government in future wishes to use data.

Geospatial data in the UK comes in many forms often today created from 'exhaust data' from other applications e.g. from mobile phone data, from company account data, from repurposed public sector data.

The quality is variable but is used extensively by the private sector for predictive analytics to 'consider potential behaviours'. The Commision might care to assist government to think through how much it chooses to 'itself' undertake this locationally based analysis on the citizen to hone public services and reduce public sector costs.

An alternative which reduces the reputational risk to government is to buy the answer from the private sector as a service or to encourage the private sector to publish the data outcomes onto which the public sector can build policy-based initiatives.

Q15: How can we best develop a single UK strategy, ensuring alignment between the individual strategies across the UK while still allowing for national variations?

The Geosptail Commision can really make a difference if it stays at a high level but ensures it measures and monitors those aspects that it strategically gives guidance upon.

It must work with the relevant stakeholder organisations both within the devloved adminstrations, the national organisations and with the representatives of the private sector. It is likely to cover aspects of:

- Organisational governance
- Standards to be adopted
- Capacity building
- The nationally needed geospatial data stack
- The portal by which it should be accessed

The Strategy should aim to maximise exploitation and benefit to everyone from geospatial information and to provide a framework to guide national, regional and local geographical initiatives.

Currently too few government owned datasets that incorporate location can be easily assembled and analysed with reliability from across local and central

government bodies. There remains:

- too much duplication,
- too little reuse
- too few linkages across datasets

The Strategy should ensure that:

1. we know as a nation and as citizens, what essential data we have access to, and avoid duplicating it
2. we use common reference data so we know we are talking about the same places
3. we can share location-related information easily through a common infrastructure of standards, technology and business relationships
4. we have the appropriate skills, both among geographic professionals and among other professional groups who use location information or support its use
5. we have strong leadership and governance to drive through change including the implementation of the Strategy

Q16: How can we best ensure effective local authority coordination and sharing of best practise, using location data to better deliver public services?

Local Authority co-ordination could be assisted by senior leaders in SOLACE and in COSLA. It also would be possible to improve effectiveness by using at the grass routes operational level, those that work in local government to provide GeoPlace with the local government inputs to the national addressing products.

Clearly, financial burdens must not be imposed on Local Government by the introduction of the Strategy but there are many incentives for them to use geospatial as many of their shared service centres already strategically use geospatial in everything they do. There are great individuals who are advocates for cost reduction by the use of geospatial in Local Government and they should be used to spread the word both to the CEO level and to the more operational staff.

The national Strategy priorities will easily translate to Local Government and hence including senior representatives in the major initial discussions on the following priorities will be essential:

- Organisational governance
- Standards to be adopted
- Capacity building
- The nationally needed data stack
- The portal by which it should be accessed

Q17: As a result of this analysis, we are prioritising the exploration of possible initiatives in the high-value categories identified:

- **property and land**
- **infrastructure and construction**
- **mobility**
- **natural resources**
- **sales and marketing**

What are the existing or potential geospatial applications which could be scaled-up or developed in order to capture economic value? (We would particularly welcome responses from industry and other bodies engaged in these sectors.)

This list seems a little constraining as geospatial could be used in so many different economically stimulating examples. I also would have thought it is for the market to develop suitable applications as opposed to government.

However, taking mobility and being very involved with encouraging disabled people to meet their full potential, I am very pleased to see that the National Rail system will have a new geolocationally enabled app https://www.bbc.co.uk/news/uk-england-45656560 and I would also encourage greater investment in this website which is underfunded but would assist greatly if further investment could be found https://accessadvisr.net. For the record I have no financial or personal investment in either [text redacted].

Q18: Are there any other areas that we should look at as a priority?

The Geospatial Commission should perhaps lead on international engagement in geospatial matters. Currently the UK involvement is fragmented with UK representatives attending multiple international fora as the 'UK government representative' but it is not clear if a knowledge of all aspects of developing international policy is being fed back and utilised by the UK government.

Q19: What are the main potential private and public sector innovations that will rely on the use of geospatial data to rollout, and are there corresponding regulatory challenges?

There are many potential public and private sector innovations that will rely on geospatial data and many that have not been invented yet. Five years ago we would not have thought the commodity trading prices can be affected by 'our industry'.

Potential regulatory challenges include:

- privacy issues including confidentiality of geospatial data that may allow individual identification;
- security issues about the collection and use of geospatial data
- regulation around the use of drones, autonomous vehicles, HAPS and other aerial platforms to collect geospatial data;

Q20: How best can we make the UK's presence in the international geospatial world more visible?

A great first step is the formation of the Geospatial Commission and the information you have supplied to date; this is attracting international attention.

Continuation of quality information generated from the Commission is essential. To date the UK has been 'behind' other nations in the fact we did not have a central co-ordination policy body unlike many nations in Europe, the Middle East, the Far East and North and South America.

The strategy and resulting policy should be published so that it can be studied and copied around the world.

The Geospatial Commision should become the lead 'policy unit' for geospatial for the UK and hence be the lead UK representative on international policy development.

The Geospatial Commision should work with DIT to assist them to embrace the export potential for the UK geospatial sector and we should be penetrating markets currently being dominated by the Republic of Korea, China and occasionally France.

Q21: Where should the UK be looking for points of comparison overseas? Who are the other international exemplars? What best practice is being modelled overseas that we can learn from?

Different countries demonstrate different aspects of best practice. No one country acts as an exemplar country.

The Nordic nations: best exemplar of devolved governments working together. This good practice is further exemplified in the Arctic SDI which has a most complicated set of countries to co-ordinate but they have used the same working practices as amongst the five nations of the Nordic SDI.

Denmark: best example of measuring the 'monetising' of Open Data

Norway: best example of local and central government working together and deriving benefits from each other

The Netherlands: good example of land registration and the geospatial framework being governed together but using Geonovum, an external body to support the implementation of best practice across the country

Abu Dhabi: a good example of 50+ organisations within one government working together to adopt the same practices and ways of working to reduce cost and improve interoperability and reuse of the data

Republic of Korea: Good example of how to attract inward investment and good example how to influence other nations to adopt their practices and sell their expertise

Singapore and Hong Kong: good examples of how the whole nation is underpinned by well maintained geospatial information

Australia: good example, despite until recently they not having a Space Agency, how they have embraced due to the size of their continent the advantages of the use of earth observation data and expressed this by moving forward on their DataCube approach

Regional centre for mapping rural development (RCMRD, Nairobi): a good example of how to get common working practices in capacity building operational across a complex region

Mexico: a good example of excellent co-ordination between their statistical and geographical frameworks, which are managed in one organisation, called INEGI. At the same time the Mexican government has shown excellent co-ordination skills to assist the building of the geospatial frameworks of the Latin American countries and also the Spanish and Portuguese speaking Caribbean Countries and in the much-needed provision of capacity building for both regions.

Geospatial Commission: Call For Evidence Response Questionnaire

Please submit your completed questionnaire to:

geospatialcommission@cabinetoffice.gov.uk.

Clearly title your email *'Call for evidence response'*.

About you and your organisation

Name	[Text redacted]
Organisation	Mallon Technology Ltd
Job title	[Text redacted]
Address	[Text redacted]
E-mail	[Text redacted]
Telephone	[Text redacted]

Please select which of the following best describes you as a respondent:

Respondent	**Please mark with a X**
Academic	
Business representative / trade body	
Central government	
Charity or social enterprise	
Individual	
Legal representative	
Local government	
Large business (over 250 staff)	
Medium business (50 to 250)	**X**
Small business (10 to 49)	
Micro business (up to 9)	

Other - please state	

Call for evidence - three key themes

We have identified three high-level themes that could help our approach to setting a strategy which are as follows:

1. **Supporting innovation in the geospatial sector**, exploring how to secure cutting edge skills, the right access to data, and opportunities from emerging technologies for the geospatial sector itself
2. **Enhancing the UK's geospatial assets,** looking at how best to align interests, avoid duplication, and instill best practice across the whole public sector
3. **Driving investment and productivity in geospatial applications**, asking in which wider sectors the most value lies from better exploitation and use of geospatial data, in the UK and internationally

Our questions

Q1. Is our view of the geospatial data types accurate? If not, what should be included or excluded from this?

Yes

Q2. In addition to current government policy, what are the areas of geospatial skills where the commission could best focus, to help ensure the necessary capability within the UK for the future?

Data analytics, machine learning, AI, access to data, data interoperability

Q3. What are the geospatial skills needs and gaps in your organisations, how can these be most effectively addressed, and how can careers in the sector be best promoted?

- Data science and machine learning skills are in short supply.

- Promote STEM at school level – events such as international GIS day and Space week can help engage schools
- Introduce schools to earth observation data (Copernicus programme)
- Promote industry opportunities to data science graduates, through placements, internships
- Introduce geospatial/earth observation post graduate programmes to data science undergrads.
- Establishment of apprenticeship programmes

Q4. Are there any publicly or privately-held geospatial datasets that are currently challenging to access or use or of insufficient quality, but which you or your organisation would find valuable if these issues could be resolved? Please explain why this would be of value, and how access/quality could be improved?

Current challenges include clarity of rights and accessibility. Lack of awareness within local authorities with regard to what data is captured/retained/managed across departments. As a result, it is difficult for third parties to source and access this data.

A central data sharing body or clear policy on data sharing could deliver transparency, facilitate sharing, implement standards and ensure data interoperability

Q5: Do you anticipate that any changes will be needed to the both address data and the wider address ecosystem, to support emerging technologies? Please provide evidence of value to support any proposed changes.

A single national address register will assist with linking a wide range of other data and assist with building value added services on the back of a single register

Q6: How should the commission be looking to develop the UK's capability in Earth observation data, both technologically and to support an effective market?

- Improve access to high-end computing facilities. Develop skills in scripting, mathematics and machine learning.
- Enagement with between Private and Public Service to promote the use of Earth observation data to aid planning, monitoring and change detection. It can be used in emergency disaster management, monitoring climate change, flooding, coastal erosion, urban planning etc
- Access to funding streams for collaborative research and development – clear guidelines on retention of IP for SMEs when collaborating with research bodies

Q7. Which new technologies should the commission focus on to provide new opportunities to process and exploit geospatial data for economic growth?

Platforms as a Servce (PAAS) – mechanisms for providing earth observation data /data cubes/satellite data archive to users. Organisations can build algorithms and create a value added service on top of such platforms.

Q8. How can geospatial data and applications be used to support enhanced roll-out of future technologies?

Geospatial data and applications can form the cornerstone of many applications by enhancing data visibility and context, aid decision making, research, geo-targeting, geoAI etc

Q9: What are the options for how public sector organisations could continue to invest in maintaining and enhancing our geospatial data assets?

Platforms for data access, develop products and services for social, economic, educational and business use. Maintain data quality standards, regular updates/data validation, positional accuracy, engage with users, promote the use of national mapping and related databases.

Q10: What areas of the underpinning geospatial infrastructure such as positioning technologies, including GPS and indoor positioning systems, and geodetic networks and frameworks to support them, should we be prioritising the development of, in order to support the emerging requirements for geospatial data?

Geodetic networks and frameworks

Q11: What role should the private sector have in both the development and maintenance of the underpinning infrastructure and enhancing the UK's geospatial data assets?

More effective collaboration, private sector can assist with driving innovation and provision of expertise

Q12. Do you face challenges when working with geospatial data from across the public sector? If so, what are they and how could value be better released? Are there any technical remedies or standards that could be adopted to improve the interoperability of geospatial data? Please provide supporting evidence of what these remedies could help to accomplish.

Challenges include clarity on data availability, what is freely available for use and how to source it.
Data standards and data interoperability issues

Q13. How can the Geospatial Commission act as a more effective customer for geospatial data on behalf of the public sector?

By communicating the value that geospatial data can bring to enhance public services and social engagement. Assisting with knowledge transfer to local authority users to foster adoption and awareness.

Q14. Are there any additional geospatial datasets, from the other partner bodies or other sources, that the public sector would derive significant benefit from having access to, that might have novel and valuable use cases? What would that access look like?

Copernicus data (Optical and SAR) can provide significant benefit to the public sector. Accessing this data through a PaaS/data cube.

Q15: How can we best develop a single UK strategy, ensuring alignment between the individual strategies across the UK while still allwoing for regional variations?

Include Geo in other national strategies including the national data strategy, national innovation strategy, national space strategy etc which will help align the single UK strategy at the core.

Q16: How can we best ensure effective local authority coordination and sharing of best practise, using location data to better deliver public services?

Through collaboration, regional investment, shared services/knowledge and policy that requires local authorities to engage with the citizen.

Q17: As a result of this analysis, we are prioritising the exploration of possible initiatives in the high-value categories identified:

- **property and land**
- **infrastructure and construction**
- **mobility**

- **natural resources**
- **sales and marketing**

What are the existing or potential geospatial applications which could be scaled-up or developed in order to capture economic value? (We would particularly welcome responses from industry and other bodies engaged in these sectors.)

GeoAI for sales and marketing category

Q18: Are there any other areas that we should look at as a priority?

Healthcare

Q19: What are the main potential private and public sector innovations that will rely on the use of geospatial data to rollout, and are there corresponding regulatory challenges?

Using earth observation data on a national scale for monitoring agriculture, food production, monitoring climate change, security etc

Q20: How best can we make the UK's presence in the international geospatial world more visible?

Promote FDI and create clusters to foster innovation, ensure that there is a diverse and large pool of talent. Government funding for R&D and collaborate internationally.

Q21: Where should the UK be looking for points of comparison overseas? Who are the other international exemplars? What best practice is being modelled overseas that we can learn from?

USA for sales and marketing innovations

Thank you for your time in completing your response to our call for evidence.

Any questions, please get in touch with the Geospatial Commission via geospatialcommission@cabinetoffice.gov.uk

Our questions

Q1. Is our view of the geospatial data types accurate? If not, what should be included or excluded from this?

We do not have sufficient expertise to provide input.

Q2. In addition to current government policy, what are the areas of geospatial skills where the commission could best focus, to help ensure the necessary capability within the UK for the future?

We do not have sufficient expertise to provide input.

Q3. What are the geospatial skills needs and gaps in your organisations, how can these be most effectively addressed, and how can careers in the sector be best promoted?

We do not have sufficient expertise to provide input.

Q4. Are there any publicly or privately-held geospatial datasets that are currently challenging to access or use or of insufficient quality, but which you or your organisation would find valuable if these issues could be resolved? Please explain why this would be of value, and how access/quality could be improved?

One million property transfer transactions are registered at HM Land Registry every year, a further 34% of transactions don't make it to completion mainly because of the delays in the process and information which comes up after the sale is agreed but which would prevent the buyer from proceeding either in relation to the property or the funding required for the purchase.

HM Land Registry data is inaccessible other than the basic information. The digitisation of documents held by them would help process key stages in the conveyancing transaction and provide information to a potential buyer in a digestible format prior to viewing.

Stamp Duty Land Tax data is submitted to HMRC on the transfer of a property but this data is currently not accessible to HMLR or the conveyancer. On the sale of the property this data could prevent seller identity fraud because the conveyancer and HM Land Registry could verify data such as the National Insurance Number,

dates of birth, etc to establish that the person they are dealing with is the genuine seller.

Similarly, providing HM Land Registry access to the DVLA and Border Control data would enable them to affix an official photograph of the Registered Proprietor to the Registers so that anyone transacting with them could easily ensure that they are dealing with the true owner.

Water Authority data is also inaccessible other than through Water Authority Searches. This causes additional costs burdens where only core data, such as connection to mains water and drainage and the route of pipes and sewers, is required but the consumer has to pay for the full search product which includes information irrelevant to the conveyancing process eg water pressure, etc.

Similarly, the exact route of drains and sewers would be extremely helpful to property owners when considering extending or altering their property and therefore with no need to carry out a full Con29DW drainage and water search.

Survey and Valuation datasets held within the private sector could also provide valuable information during the conveyancing process.

Obtaining information, held by both private and public bodies, relating to the management of Leasehold estates or managed Freeholds adds an additional 20 days to the conveyancing of these properties. Having immediate access to these datasets would inform potential buyers of their financial obligations prior to viewing and offer, and reduce wastage through transactional failures and delays.

There are issues with the quality of planning and building regulation data dependant upon the systems used and accessibility permitted by the Local Authority. Whilst the planning portal is a helpful asset it is hit and miss. Enabling access to the datasets would speed up the home moving process whilst at the same time making the planning process more transparent and providing valuable information to emergency services on changes and access to the building.

Q5: Do you anticipate that any changes will be needed to the both address data and the wider address ecosystem, to support emerging technologies? Please provide evidence of value to support any proposed changes.

Address data and the identification of land and the buildings located on it is currently flawed. HMRC work off the UPRN for the Stamp Duty Land Tax Return but HMLR use their Title Number. There are difficulties where the taxonomy of flats is non-standard so that a Ground Floor Flat might be described as GFF Acacia Avenue or Flat 1 Acacia Avenue, Flat A Acacia Avenue or Garden Flat, Acacia Avenue.

Changes will therefore need to be introduced to either standardise addresses or link them to one agreed unique identifier which should be attributed to the property when it is allocated planning permission. There is a problem in property where a plot is given a plot number which changes through the conveyancing process to the postal address. This means that some lenders have to re-issue mortgage offers to update them with the postal address and that some documents stored at HM Land Registry refer to the Plot rather than the registered address causing confusion and, in some cases, necessitating Deeds of Variation.

Q6: How should the commission be looking to develop the UK's capability in Earth observation data, both technologically and to support an effective market?

We do not have sufficient expertise to provide input.

Q7. Which new technologies should the commission focus on to provide new opportunities to process and exploit geospatial data for economic growth?

A big issue in the conveyancing sector is the inability for systems to integrate with each other and this is the same across all of Government and industries. Basic standardisation of field names would go a long way to enabling datasets to be interoperable.

If all users of Government datasets and all Government departments and Local Authorities were required to provide an API then this could be avoided and data could flow more easily.

The development of a form of Babel fish technology which can translate one

dataset into the appropriate field names of another database would assist.

In the property transfer process much of the 18-week process is the collation of data which will be lost once the transaction is completed. By storing this data in an authenticated ledger then it could be accessed for the next transaction.

Distributed ledger technologies should be supported to establish their workability for this purpose.

Q8. How can geospatial data and applications be used to support enhanced roll-out of future technologies?

We do not have sufficient expertise to provide input.

Q9: What are the options for how public sector organisations could continue to invest in maintaining and enhancing our geospatial data assets?

We do not have sufficient expertise to provide input.

Q10: What areas of the underpinning geospatial infrastructure such as positioning technologies, including GPS and indoor positioning systems, and geodetic networks and frameworks to support them, should we be prioritising the development of, in order to support the emerging requirements for geospatial data?

We do not have sufficient expertise to provide input.

Q11: What role should the private sector have in both the development and maintenance of the underpinning infrastructure and enhancing the UK's geospatial data assets?

We do not have sufficient expertise to provide input.

Q12. Do you face challenges when working with geospatial data from across the public sector? If so, what are they and how could value be better released? Are there any technical remedies or standards that could be adopted to improve the interoperability of geospatial data? Please provide supporting evidence of what these remedies could help to accomplish.

Yes, please see our answer to Quesitons 4 and 7

Q13. How can the Geospatial Commission act as a more effective customer for geospatial data on behalf of the public sector?

We do not have sufficient expertise to provide input.

Q14. Are there any additional geospatial datasets, from the other partner bodies or other sources, that the public sector would derive significant benefit from having access to, that might have novel and valuable use cases? What would that access look like?

We do not have sufficient expertise to provide input.

Q15: How can we best develop a single UK strategy, ensuring alignment between the individual strategies across the UK while still allwoing for regional variations?

Create industry and regional working groups to input into the single UK strategy and feedback to their industries and regions as the strategy develops.

Q16: How can we best ensure effective local authority coordination and sharing of best practise, using location data to better deliver public services?

Resource the Local Authorities independently for this purpose. Local Authorities are required to be the custodians of many geospatial datasets through regulation and statute and yet the requirements have not in the past come with any ring-fenced funding meaning they have had to find funding within their own budgets.

This has resulted in failure to maintain datasets, for example many Local Authorities have not had the funds available to create a register of contaminated land required by the Environment Protection Act 1990.

The creation of webforms for all applications to Local Authorities coupled with properly resourced and mandated standardisation of datafield taxonomy and the provision of an API would immediately enhance coordination whilst leaving Local Authorities free to chose their preferred system supplier and maintain competition amongst the suppliers.

Q17: As a result of this analysis, we are prioritising the exploration of possible initiatives in the high-value categories identified:

- **property and land**
- **infrastructure and construction**
- **mobility**
- **natural resources**
- **sales and marketing**

What are the existing or potential geospatial applications which could be scaled-up or developed in order to capture economic value? (We would particularly welcome responses from industry and other bodies engaged in these sectors.)

96% of home owners say that they did not receive sufficient information prior to making an offer on a property. Even during the conveyancing process, as the data is collated, it conflicts with with previous information generating additional enquiries. If Local Authority along with other public authority and private data was accessible at the point of marketing and used to populate standard and pan-industry approved datasets, we could remove much of the conflict and confusion through the process.

If a lender, and their valuer, was able to assess the available property data and open banking data they would also be able to provide a binding lending decision within a matter of minutes.

Current conveyancing transaction times are 18 weeks.

One million residential properties are transacted every year. There are another 340,000 transactions which fail. That equates to 2.68 million families in economic stasis for up to 18 weeks every year. They can't book holidays, buy sofas or arrange removals because they do not know when or if they are moving.

By freeing the barriers between geospatial data, huge economic value could be derived, not to mention the positive emotional impact of a smooth and efficient transaction.

Q18: Are there any other areas that we should look at as a priority?

Access to datasets to assist emergency services.

Q19: What are the main potential private and public sector innovations that will rely on the use of geospatial data to rollout, and are there corresponding regulatory challenges?

We do not have sufficient expertise to provide input.

Q20: How best can we make the UK's presence in the international geospatial world more visible?

We do not have sufficient expertise to provide input.

Q21: Where should the UK be looking for points of comparison overseas? Who are the other international exemplars? What best practice is being modelled overseas that we can learn from?

We do not have sufficient expertise to provide input.

Thank you for your time in completing your response to our call for evidence.

Any questions, please get in touch with the Geospatial Commission via geospatialcommission@cabinetoffice.gov.uk

Geospatial Commission: Call For Evidence Response Questionnaire

Small business (10 to 49)	
Micro business (up to 9)	

Other - please state	**X We are a network of organisations from across the UK public and private sectors, with an interest in marine geospatial data. Our sponsors come from both the public and private sectors.**

Call for evidence - three key themes

We have identified three high-level themes that could help our approach to setting a strategy which are as follows:

1. **Supporting innovation in the geospatial sector**, exploring how to secure cutting edge skills, the right access to data, and opportunities from emerging technologies for the geospatial sector itself
2. **Enhancing the UK's geospatial assets,** looking at how best to align interests, avoid duplication, and instill best practice across the whole public sector
3. **Driving investment and productivity in geospatial applications**, asking in which wider sectors the most value lies from better exploitation and use of geospatial data, in the UK and internationally

Our questions

Q1. Is our view of the geospatial data types accurate? If not, what should be included or excluded from this?

Yes.
The Marine Environmental Data and Information Network (MEDIN) is an open network of UK organisations committed to increasing access to marine environmental data. For the past decade, MEDIN has been working with hundreds of organisations to make marine geospatial data openly and easily available. MEDIN currently provides access to over 220 TB of marine geospatial data via its network of specialist data centres:

UK Hydrographic Office (bathymetry data);
British Oceanographic Data Centre (water column oceanography data);
British Geological Survey (marine geology and geophysics data);
Met Office (marine meteorological data);
DASSH (marine species and habitats data);
Marine Scotland; Cefas (fisheries data);
Archaeology Data Service; Historic Environment Scotland; Royal Commission on the Ancient and Historic Monuments Wales (marine historic environment data).

MEDIN has 10 years' experience working with the three high-level themes identified above and is keen to work with the Geospatial Commission to share knowledge, avoid duplication and continue to enhance the UK's geospatial assets.

Q2. In addition to current government policy, what are the areas of geospatial skills where the commission could best focus, to help ensure the necessary capability within the UK for the future?

While supporting geospatial skill training as a necessary enabling activity, MEDIN has learnt that these skills need to be developed alongside specialist knowledge of the data in question. In other words, geospatial data skills need to be taught across many disciplines, as specialised knowledge is required to interpret specialist data.

For example, an analyst of storm surge geospatial data would not be able to make use of the data to better protect UK's coastal towns and cities without in-depth knowledge of the interaction between tides, currents, waves and weather (ocean science).

With this in mind, any training developed by the commission should be modular in nature and developed in such a way that it can be easily embedded in relevant degree and other courses.

Marine science is multidisciplinary in nature and so this sort of modular approach is relatively common.

Q3. What are the geospatial skills needs and gaps in your organisations, how can these be most effectively addressed, and how can careers in the sector be best promoted?

In ocean science, there can be a divergence between the tools for geospatial analysis taught by universities and those most commonly used in jobs in the commercial and public sectors. Desktop Geographic Information System (GIS) tools are commonly used for mapping terrestrial parameters and are also useful for mapping seabed features and habitats. However, these tools are not always taught in pure marine science courses as they are not generally appropriate for the marine environment, except as said above. Teaching spatial analysis skills rather than specific tools may be more beneficial in the long run.

There are unique aspects to the marine environment that require marine specific approaches. Analysing or visualising the full depth ocean environment, which, as

it is constantly changing in time, is a 4-dimensional problem. The oceans or indeed many of the species that live in them do not stay still and so do not lend themselves to being mapped in 2- or -3 dimensions. 4-dimensional tools are required for marine geospatial analysis and visualisation.

Q4. Are there any publicly or privately-held geospatial datasets that are currently challenging to access or use or of insufficient quality, but which you or your organisation would find valuable if these issues could be resolved? Please explain why this would be of value, and how access/quality could be improved?

MEDIN provides access to over 220 TB of marine data owned or managed by over 500 different organisations. For the past 10 years, MEDIN has been working with the UK marine community to increase access to marine environmental data from both the public and private sectors. Providing access to geospatial datasets is not a one off activity but is a continual process, engaging with new data collectors, encouraging the adoption of standards etc. The number of geospatial marine datasets accessible from MEDIN has grown year on year, from around 800 in 2010 to over 14,000 in 2018.

A significant portion of the public sector data accessible from MEDIN are available under the Open Government License.

Data from long established commercial sectors, such as the oil and gas industry, have traditionally been the hardest to gain open access to. However, recent changes to legislation should facilitate this. In contrast, newer commercial marine industries, such as the offshore renewable energy sector, make the majority of their marine environmental data accessible, thanks to a data clause included in The Crown Estate's tenancy agreements. Nevertheless, the cost to archive data in specialist data centres remains a barrier to making some privately-held datasets openly available.

Historically, some organisations have wanted to "hold on to" their geospatial data as they considered it commercially or academically sensitive. Within the marine sector, this is well understood and MEDIN ensures that data can be "embargoed" within its data centres until a point when it is no longer considered sensitive.

There are significant gaps in our knowledge of the global seafloor depth (bathymetry). This is a fundamental dataset with a range of applications and uses including safe trade; military and defence; understanding our planet; and for addressing the challenges associated with climate change; and has led to the establishment of the Nippon Foundation GEBCO Seabed 2030 Project. This is an

international effort with the objective of facilitating the complete mapping of the world ocean by 2030. The resultant data sets produced through this project will be available to the international community, for scientific/academic/commercial use.

Q5: Do you anticipate that any changes will be needed to the both address data and the wider address ecosystem, to support emerging technologies? Please provide evidence of value to support any proposed changes.

The British Standard defines an address as ‘a means of referencing an object for the purposes of unique identification and location’. Noting that geospatial data can be marine as well as terrestrial, we strongly recommend that emerging technologies are developed to recognise that a “postal address” is not always appropriate for geospatial data. The UK has many structures offshore e.g. oil and gas rigs, wind turbines etc. These structures situated in marine locations do not, and should not, have postal addresses or postcodes.

Some datasets span both the terrestrial and marine environment (e.g. aerial monitoring, satellite images, intertidal surveys, etc.). Address systems (positional identification systems) need to be applicable to both land and sea. Changing address systems at the coast is not useful in these situations and can cause confusion and costly errors. Latitude and longitude, provided with the appropriate coordinate reference system are suitable for both terrestrial and marine geospatial data.

Q6: How should the commission be looking to develop the UK’s capability in Earth observation data, both technologically and to support an effective market?

We have learnt that a successful model for marine data is a distributed network of specialist data centres. For marine data these are currently:

UK Hydrographic Office (bathymetry data);
British Oceanographic Data Centre (water column oceanography data);
British Geological Survey (marine geology and geophysics data);
Met Office (marine meteorological data);
DASSH (marine species and habitats data);
Marine Scotland; Cefas (fisheries data);
Archaeology Data Service; Historic Environment Scotland; Royal Commission on the Ancient and Historic Monuments Wales (marine historic environment data).

MEDIN would highly recommend using specialist data centres to archive, analyse and disseminate the highly specialised Earth Observation (EO) data. The Geospatial Commission should fund these activities at a specialist data centre and then provide additional training and support to customers wanting to use EO data but are lacking the appropriate skills to do so.

Q7. Which new technologies should the commission focus on to provide new opportunities to process and exploit geospatial data for economic growth?

Q7. Which new technologies should the commission focus on to provide new opportunities to process and exploit geospatial data for economic growth?

MEDIN recognises that there is a difference between a dataset and a data product. Both of these can be geospatial but the latter has some level of collation, interpolation or interpretation involved that adds value to the contributing datasets. MEDIN's focus is on providing access to marine geospatial datasets, not to producing data products.

Big data technologies that allow users to access and synthesise data from disparate but standardised sources combined with free access to the underlying data would encourage market entrants into the value-added products space.

Q8. How can geospatial data and applications be used to support enhanced roll-out of future technologies?

The ever increasing volume of marine data is driving a need for “Big Data” tools, high volume storage and High Performance Computing.

Q9: What are the options for how public sector organisations could continue to invest in maintaining and enhancing our geospatial data assets?

We have learnt that a successful model for marine data is a distributed network of specialist data centres. For marine data these are currently:

UK Hydrographic Office (bathymetry data);
British Oceanographic Data Centre (water column oceanography data);
British Geological Survey (marine geology and geophysics data);
Met Office (marine meteorological data);
DASSH (marine species and habitats data);
Marine Scotland; Cefas (fisheries data);
Archaeology Data Service; Historic Environment Scotland; Royal Commission on the Ancient and Historic Monuments Wales (marine historic environment data).

MEDIN strongly advocates that public sector data are archived at specialist data centres, that will provide long-term access to that data alongside the specialist knowledge needed to quality control, future proof and distribute that data. In general, public sector data should be made available under an open license such as the Open Government License.

In order to ensure this happens, MEDIN recommends the Geospatial Commission ensures all public sector data collection contracts include a data clause (making it mandatory to ensure data are accessible via specialist data centres). The Geospatial Commission should also ensure that the costs for managing and disseminating public geospatial data assets are included in all projects from the outset.

Public sector organizations would be aided in their public sector mission by clear separation of investment in data access from creation of value-added products.

Q10: What areas of the underpinning geospatial infrastructure such as positioning technologies, including GPS and indoor positioning systems, and geodetic networks and frameworks to support them, should we be prioritising the development of, in order to support the emerging requirements for geospatial data?

No comment

Q11: What role should the private sector have in both the development and maintenance of the underpinning infrastructure and enhancing the UK's geospatial data assets?

MEDIN's experience of working with a cross section of the marine community has shown that a collaborative approach ensures buy in from all sectors. However, it is with the private sector that we have most problems of engagement and where further work is needed and planned.

Experience in other industries, e.g. retail energy, has demonstrated that clear delineation in the data value chain aids innovation and stimulates economic growth. The private sector is best placed to focus on value-added products built on IP and freely available data.

Q12. Do you face challenges when working with geospatial data from across the public sector? If so, what are they and how could value be better released? Are there any technical remedies or standards that could be adopted to improve the interoperability of geospatial data? Please provide supporting evidence of what these remedies could help to accomplish.

Throughout its history, MEDIN has been developing and championing the adoption of marine data standards to improve interoperability.

MEDIN has developed a marine specific discovery metadata standard to improve interoperability of geospatial data (a marine profile of INSPIRE). In addition, MEDIN provides a suite of thematic data guidelines to ensure reusability and interoperability of marine data. MEDIN provides advice on these standards and guidelines internationally and is happy to share these experiences and tools with the Geospatial Commission.

Q13. How can the Geospatial Commission act as a more effective customer for geospatial data on behalf of the public sector?

No comment.

Q14. Are there any additional geospatial datasets, from the other partner bodies or other sources, that the public sector would derive significant benefit from having access to, that might have novel and valuable use cases? What would that access look like?

No comment.

Q15: How can we best develop a single UK strategy, ensuring alignment between the individual strategies across the UK while still allwoing for regional variations?

We have learnt that it is not just regional variations that need to be taken into consideration when developing a single UK geospatial strategy, but we need a strategy that the marine sector can implement in a marine-specific context.

MEDIN developed a single UK strategy for marine geospatial data for the Marine Science Coordination Committee and is happy to share this experience with the Geospatial Commission.

Q16: How can we best ensure effective local authority coordination and sharing of best practise, using location data to better deliver public services?

No comment.

Q17: As a result of this analysis, we are prioritising the exploration of possible initiatives in the high-value categories identified:

- **property and land**
- **infrastructure and construction**
- **mobility**
- **natural resources**
- **sales and marketing**

What are the existing or potential geospatial applications which could be scaled-up or developed in order to capture economic value? (We would particularly welcome responses from industry and other bodies engaged in these sectors.)

Coastal defence of UK infrastructure.
Sustainable use of ocean resources.

Q18: Are there any other areas that we should look at as a priority?

Defence and mitigation from environmental hazards such as:

- storm surges and coastal flooding
- sea level rise
- seafood security in a changing climate
- predicting extreme events

To put the first of these into context, coastal flooding is rated as the second highest risk of civil emergency in the UK, after pandemic influenza (National Risk Registry of Civil Emergencies, 2017). Consequences of coastal flooding can include fatalities and casualties; widespread damage to property and infrastructure; disruption to essential services, particularly transport and energy; environmental damage and contamination.

Q19: What are the main potential private and public sector innovations that will rely on the use of geospatial data to rollout, and are there corresponding regulatory challenges?

No comment.

Q20: How best can we make the UK's presence in the international geospatial world more visible?

Membership and ultimately chair of relevant committees. Strive to ensure a two-way flow of information. MEDIN is already well connected to EU and other relevant international geospatial organisations.

Use success stories such as MEDIN as examples of how UK is at the vanguard of best practise.

Q21: Where should the UK be looking for points of comparison overseas? Who are the other international exemplars? What best practice is being modelled overseas that we can learn from?

MEDIN, INSPIRE, OGC.

Geospatial Commission: Call For Evidence Response Questionnaire

Other - please state	

Call for evidence - three key themes

We have identified three high-level themes that could help our approach to setting a strategy which are as follows:

1. **Supporting innovation in the geospatial sector**, exploring how to secure cutting edge skills, the right access to data, and opportunities from emerging technologies for the geospatial sector itself
2. **Enhancing the UK's geospatial assets,** looking at how best to align interests, avoid duplication, and instill best practice across the whole public sector
3. **Driving investment and productivity in geospatial applications**, asking in which wider sectors the most value lies from better exploitation and use of geospatial data, in the UK and internationally

Our questions

Q1. Is our view of the geospatial data types accurate? If not, what should be included or excluded from this?

Seems a sensible definition for static data in point 2. However we deal with a lot of live data. Both raster and point data. This is growing rapidly in importance. The Met Office has been doing a lot at the OGC in defining how it should be formed. This yet to come into the traditional GI space. Generally lacking is guidance on a standard way to manage such data to allow re-use and tie into a particular format. This needs to be added.

Q2. In addition to current government policy, what are the areas of geospatial skills where the commission could best focus, to help ensure the necessary capability within the UK for the future?

There is a tendency within IT based organisations such as the Met Office to adopt a slice of Geospatial technology that fits the current technology fashion an extension of the programmers existing knowledge. It is often not re-usable and uses formats that come and go. There is a lack of understanding of the whole geo-spatial “space” is delaying the sharing of capability. We need to reduce the barriers to entry at every level

Training

- Senior managers/leaders need to understand the value of GI teams make to an organisation. In terms of capability and outreach.
- At least one System Architect in an organisation should understand what’s happening in commercial GIS in any organisation.
- More incentives for GIS Apprentices
- Non degree level qulifications to go along side Apprenticeships NVQ? Reduce the barriers to entry
- In schools add it to curriculums beyond Geography bring into Science,Mathematics,History,RE. Similiarly in higher levels of education.

Q3. What are the geospatial skills needs and gaps in your organisations, how can these be most effectively addressed, and how can careers in the sector be best promoted?

We need to bring skills together questions like do we do geospatial in the database or in the client? These are never answered. We need multi disciplined teams with strong GI lead.What form the data should be and the software capability is done in terms of expediency to do a particular project. No long term vision. Any system such as a GIS that will fullfill a range of needs can be easily ignored to get to the immediate goal.

We need people capable of understanding the whole picture. GI teams in many organisations are often too small and beleaguered.

So we need :

- Mult-displine teams of GIS, programmers and database experts thrown together
- A recognition of the value of people who take the time to understand the wider GI domain. Can we have a career beyond GIS Analyst?

Q4. Are there any publicly or privately-held geospatial datasets that are currently challenging to access or use or of insufficient quality, but which you or your organisation would find valuable if these issues could be resolved?

Please explain why this would be of value, and how access/quality could be improved?

Ordnance Survey NI why is different from Ordnance Survey? Can't they use the same resolutions, same raster mapping style? Why can't I get hold of OSNI in the PSMA? Similiarly why is SEPA data different resolutions from EA data? Can't we be UK? Can't it be a web service? This would save so much work.

Each organisation is collating data from the OS in little files. Can't it be supplied as a mosaic ready to load. No more GML which needs translating. A web service may help with this.Again individual organisational effort.

Now a critism of my own organisation. Why can't anyone just access via a web service/download Met Office data and use it in a GIS without translation. Also discover it easily. It doesn't have to be everything just the most useful. This again would enable many users who are not programmers. Save effort and consultancy.

Q5: Do you anticipate that any changes will be needed to the both address data and the wider address ecosystem, to support emerging technologies? Please provide evidence of value to support any proposed changes.

We need NI data in the PSMA..

Q6: How should the commission be looking to develop the UK's capability in Earth observation data, both technologically and to support an effective market?

Easily accessable live feeds of satellite ground imagery, weather, tidal and flood to support major incidents / disaster responses.

Q7. Which new technologies should the commission focus on to provide new opportunities to process and exploit geospatial data for economic growth?

- **Centralised discovery of ready to consume GI data. Discovery portal bringing together existing sources.**
-
- **Build it as one source of truth for UK data**
- **Standardised real time methodologies so data streams can readily be consumed by basic GIS tools and instructions**

Q8. How can geospatial data and applications be used to support enhanced roll-out of future technologies?

Easy to find, ready to use data well defined data from the point of truth organisation will be an enabler. It must be quick otherwise users will find something else to consume right or wrong.

Applications that allow youu to discover, check against other data again will enable.

Q9: What are the options for how public sector organisations could continue to invest in maintaining and enhancing our geospatial data assets?

GIS able young people were the first to go from my organisation when pay tightened and the specture of reduncies loomed. They have the ability to change jobs however were the life blood of a better future. There is less time to advocate and explore new ways of doing things. We need to ensure public organisations have the mandate to:

- Maintain core GIS capabilities
- Have a senior role to push through time saving capabilities across the organisation and engage with other organisations.
- Organisations should be given a mandatory requirement to provide GI data in an easy to consume form. 3 Clicks! Discover,Check,Consume!
- Mandate organisations must retain GI capability
- As resources are short facilitate GI people from other organisations to blitz start new GI projects to share data.

Q10: What areas of the underpinning geospatial infrastructure such as positioning technologies, including GPS and indoor positioning systems, and geodetic networks and frameworks to support them, should we be prioritising the development of, in order to support the emerging requirements for geospatial data?

N/A

Q11: What role should the private sector have in both the development and maintenance of the underpinning infrastructure and enhancing the UK's geospatial data assets?

They have the reach and understanding of a group of sectors that exceeds a Government Department. They can encourage and facilitate the sharing of geospatial information and demonstrate the benefits.

They can adopt the common stanadards fully or if they can't improve them to ensure interoperability.

Q12. Do you face challenges when working with geospatial data from across the public sector? If so, what are they and how could value be better released?

Are there any technical remedies or standards that could be adopted to improve the interoperability of geospatial data? Please provide supporting evidence of what these remedies could help to accomplish.

Finding it is the major headache then finding you cannot use it or a bits missing. A central search engine using OGC and commercial standards (e.g. WCS,WMS,WFS, REST services). API's that allow standard data forms tif,shape,netcdf

Common standards to real time data. Even a simple one would be better than non at all.

Q13. How can the Geospatial Commission act as a more effective customer for geospatial data on behalf of the public sector?

Push the PSMA to cover the whole UK and provide web services

Provide examples of good practice with the minimum you can get away with!

Q14. Are there any additional geospatial datasets, from the other partner bodies or other sources, that the public sector would derive significant benefit from having access to, that might have novel and valuable use cases? What would that access look like?

- OSNI datasets.
- Met Office UK Climate data. Met Office Observations in a form that goes straight into a GIS. Soil Moisture calculations. Some Forecast elements.

You discover by keywords, check whether data is fit for purpose and you pull it in.

Q15: How can we best develop a single UK strategy, ensuring alignment between the individual strategies across the UK while still allwoing for regional variations?

A UK National Strategy would be welcome.

- Make it a minimum standard. Inspire was a nightmare also GML
- Allow national level purchasing of complient software “bulk buy”

But it must be kept up to date with annual reviews and keep up with new standards and technologies. Must be on going or it will die.

Q16: How can we best ensure effective local authority coordination and sharing of best practise, using location data to better deliver public services?

Bit out of my remit

Q17: As a result of this analysis, we are prioritising the exploration of possible initiatives in the high-value categories identified:

- **property and land**
- **infrastructure and construction**
- **mobility**
- **natural resources**
- **sales and marketing**

What are the existing or potential geospatial applications which could be scaled-up or developed in order to capture economic value? (We would particularly welcome responses from industry and other bodies engaged in these sectors.)

We would add “protection of life”.

Q18: Are there any other areas that we should look at as a priority?

Q19: What are the main potential private and public sector innovations that will rely on the use of geospatial data to rollout, and are there corresponding regulatory challenges?

Q20: How best can we make the UK's presence in the international geospatial world more visible?

Get the data up there in an easy to consume form

Q21: Where should the UK be looking for points of comparison overseas? Who are the other international exemplars? What best practice is being modelled overseas that we can learn from?

We often look to the US https://www.fgdc.gov/nsdi-plan/nsdi-strategic-plan-2014-2016-FINAL.pdf

Perhaps we can learn from them.

Thank you for your time in completing your response to our call for evidence.

Any questions, please get in touch with the Geospatial Commission via geospatialcommission@cabinetoffice.gov.uk

Geospatial Commission: Call For Evidence Response Questionnaire

Please submit your completed questionnaire to:

geospatialcommission@cabinetoffice.gov.uk.

Clearly title your email *'Call for evidence response'*.

About you and your organisation

Name	[Text redacted]
Organisation	Met Office
Job title	[Text redacted]
Address	[Text redacted]
E-mail	[Text redacted]
Telephone	[Text redacted]

Please select which of the following best describes you as a respondent:

Respondent	**Please mark with a X**
Academic	**x**
Business representative / trade body	
Central government	
Charity or social enterprise	
Individual	
Legal representative	
Local government	
Large business (over 250 staff)	
Medium business (50 to 250)	
Small business (10 to 49)	
Micro business (up to 9)	

Other - please state	

Call for evidence - three key themes

We have identified three high-level themes that could help our approach to setting a strategy which are as follows:

1. **Supporting innovation in the geospatial sector**, exploring how to secure cutting edge skills, the right access to data, and opportunities from emerging technologies for the geospatial sector itself
2. **Enhancing the UK's geospatial assets,** looking at how best to align interests, avoid duplication, and instill best practice across the whole public sector
3. **Driving investment and productivity in geospatial applications**, asking in which wider sectors the most value lies from better exploitation and use of geospatial data, in the UK and internationally

Our questions

Q1. Is our view of the geospatial data types accurate? If not, what should be included or excluded from this?

Yes

Q2. In addition to current government policy, what are the areas of geospatial skills where the commission could best focus, to help ensure the necessary capability within the UK for the future?

Big data mash-up tools, open source code and individuals trained (or possibly a dedicated team to support others) in analyses of large geospatial data – to enable quick and efficient analyses of large geospatial (and non-geospatial) datasets with diverse formats, projections etc.

Q3. What are the geospatial skills needs and gaps in your organisations, how can these be most effectively addressed, and how can careers in the sector be best promoted?

More integration of GIS data (shapefiles) and applications with data and models used with meteorological observations and modelling (typically using python or FORTRAN code).
One way to address this is through common data formats, possibly via simple data conversion applications or through conversion of a few key meteorological indicators into GIS format for use with GIS applications (lots of questions to address if doing this).
Careers in this could be promoted through well-funded projects including PhD studentships that involve use of such differing data across organisations.

Q4. Are there any publicly or privately-held geospatial datasets that are currently challenging to access or use or of insufficient quality, but which you or your organisation would find valuable if these issues could be resolved? Please explain why this would be of value, and how access/quality could be improved?

No one dataset in particular, but in general very large geospatial datasets i.e. global and/or high resolution and/or multi-layer, and/or with differing characteristics such as projection, resolution…

Q5: Do you anticipate that any changes will be needed to the both address data and the wider address ecosystem, to support emerging technologies? Please provide evidence of value to support any proposed changes.

Human health – more personalised and patient participant health outcomes

Plant and Animal Health – more potential observations of high risk pests/pathogen

Q6: How should the commission be looking to develop the UK's capability in Earth observation data, both technologically and to support an effective market?

Enabling simple data mash-ups – comparing high-resolution satellite data and ground-based observations

Research to understand relationships between EO data and ecosystem processes e.g. carbon uptake, crop productivity…

Q7. Which new technologies should the commission focus on to provide new opportunities to process and exploit geospatial data for economic growth?

Drone observations – to provide bridge between wider EO data and ground/point observations
…in order to support understanding of the relationships between EO data and ecosystem processes and scaling up/down of processes.

Q8. How can geospatial data and applications be used to support enhanced roll-out of future technologies?

Early warning systems - Continuous monitoring of surface changes e.g. coastal erosion, crop productivity…that can be used with new technologies of ground-base monitoring e.g. plant and animal health, coastal erosion…, to help target rapid on-the-ground actions.

Q9: What are the options for how public sector organisations could continue to invest in maintaining and enhancing our geospatial data assets?

Research and modelling of the relationships between EO data and ground observations and processes.

Q10: What areas of the underpinning geospatial infrastructure such as positioning technologies, including GPS and indoor positioning systems, and geodetic networks and frameworks to support them, should we be prioritising the development of, in order to support the emerging requirements for geospatial data?

Don’t know

Q11: What role should the private sector have in both the development and maintenance of the underpinning infrastructure and enhancing the UK’s geospatial data assets?

Near surface (i.e. drone, aeroplane) and ground based sensor development for range of sectors and observations, e.g. personalised health monitoring, plant productivity for agriculture…

Q12. Do you face challenges when working with geospatial data from across the public sector? If so, what are they and how could value be better released? Are there any technical remedies or standards that could be adopted to improve the interoperability of geospatial data? Please provide supporting evidence of what these remedies could help to accomplish.

Yes, challenges associated with:

- IPR – some geospatial data are restricted
- Processing large datasets – computing resource and programming capability to analyse large geospatial datasets
- Combining raster and vector datasets e.g. we use many (raster) gridded observations and model data which are not always easy to compare with vector data such as shapefiles

Evidence of remedy:

- Developments with (open source) python/IRIS programming have helped with data format conversion and analyses of EO gridded data.

Q13. How can the Geospatial Commission act as a more effective customer for geospatial data on behalf of the public sector?

The Commission could support development of a standard set of software tools and/or code available in open source language e.g. python, python/IRIS, and on a code repository e.g GitHub, GitLab (developers working together) for reading in and simple analyses of a wide range of geospatial datasets.

Q14. Are there any additional geospatial datasets, from the other partner bodies or other sources, that the public sector would derive significant benefit from having access to, that might have novel and valuable use cases? What would that access look like?

Bluesky tree mapping
Met Office WOW (Weather on Web) citizen science weather observation network
Met Office pollen monitoring network

Q15: How can we best develop a single UK strategy, ensuring alignment between the individual strategies across the UK while still allwoing for regional variations?

Rather than enforcing/encouraging use of same data formats or selecting specific datasets for interoperability, it would be more flexible to provide tools/code for enabling comparison between the different data formats…this way more data of wider formats etc can be included and the overhead would be to add new code/tools for reading this data and enabling it to be compared with other geospatial data.
Also, provide 'recipes' for comparing datasets e.g. regridding guidance and steps to take, or even code to do these steps.

Q16: How can we best ensure effective local authority coordination and sharing of best practise, using location data to better deliver public services?

Start by asking local authorities what they need to improve most using geospatial data, then help them to do this…where possible apply this to other authorities if they also need such improvements.

Q17: As a result of this analysis, we are prioritising the exploration of possible initiatives in the high-value categories identified:

- **property and land**
- **infrastructure and construction**

- **mobility**
- **natural resources**
- **sales and marketing**

What are the existing or potential geospatial applications which could be scaled-up or developed in order to capture economic value? (We would particularly welcome responses from industry and other bodies engaged in these sectors.)

Personal health monitoring – fitness and general health monitoring, linking with GP guidance and alerts, public health warning targeted to most vulnerable persons…

Farming and other ecosystem management – linked with weather and climate monitoring, soil moisture and condition monitoring, pests and disease monitoring and surveillance, fire monitoring…

Q18: Are there any other areas that we should look at as a priority?

Human health

Plant and Animal Health including new and emerging pests/pathogen (if not covered already under Natural Resources)

Q19: What are the main potential private and public sector innovations that will rely on the use of geospatial data to rollout, and are there corresponding regulatory challenges?

Computer code/tools for enabling easy comparison of geospatial datasets.

Q20: How best can we make the UK's presence in the international geospatial world more visible?

Enabling public access to publically appealing (e.g. bird migration and weather data/systems together) geospatial data on platforms such as google earth.

Providing web tools that give early warning info for farmers and other weather/climate, or air/water pollution sensitive sectors…linked with forecasts.

Provide regular updated data/indicators from the UK CCRA (Climate Change Risk Assessment) on easy to use web tool e.g google earth like.

Q21: Where should the UK be looking for points of comparison overseas? Who are the other international exemplars? What best practice is being modelled overseas that we can learn from?

ESA Climate Change Indicators CCI's

USDA Drought monitor for farmers in US

EEA Environmental Indicators

Thank you for your time in completing your response to our call for evidence.

Call for evidence - three key themes

We have identified three high-level themes that could help our approach to setting a strategy which are as follows:

1. **Supporting innovation in the geospatial sector**, exploring how to secure cutting edge skills, the right access to data, and opportunities from emerging technologies for the geospatial sector itself
2. **Enhancing the UK's geospatial assets,** looking at how best to align interests, avoid duplication, and instill best practice across the whole public sector
3. **Driving investment and productivity in geospatial applications**, asking in which wider sectors the most value lies from better exploitation and use of geospatial data, in the UK and internationally

Our questions

Q1. Is our view of the geospatial data types accurate? If not, what should be included or excluded from this?

When developing a National Geospatial Strategy, it is important to base it on a clear understanding of not only different data types (which the Call for Evidence notes) but also the distinction between data, information and for example predictions – which present different challenges to static data – and it may be helpful for the Geospatial Commission to consider greater clarity of its focus in this regard.

For example in the Met Office we use meteorological observation data to initialise our physical weather and climate model, which drives our forecasts and services: both of which are information, based on predictions rather than data. So with these distinctions we would not tend to describe such geospatial services as a data type.

Similarly, the word 'services' in the naming of the fourth data type "Geospatial Services" could create confusion. Perhaps geospatial insights or geospatial products would better describe this class of data.

Q2. In addition to current government policy, what are the areas of geospatial skills where the commission could best focus, to help ensure the necessary capability within the UK for the future?

As a science and technology organisation, and working regularly with geospatial organisations including the Partner Bodies, we support action to build geospatial skills and capabilities for the future, including in areas such as GIS, data science and data analytics and importantly for this skills development to take place right across the UK.

With regard to producing graduates with appropriate geospatial skills, it may be worth considering whether valuable core skills are covered appropriately across a range of relevant courses. For example as a large employer of maths, physical sciences and geography graduates we have seen that there can be inconsistency in the level of digital and programming skills which are taught as part of undergraduate degree courses with the result that we have had to provide additional training in these core skills to fill the gaps. These skills are increasingly vital to tackling geospatial problems, so consideration of ways to ensure a baseline standard across courses would be beneficial both to students and employers.

Employers can have an important role to play in ensuring graduates (at all levels) have appropriate skills by working closely with education providers in the development of courses or initiatives. For example the Met Office is supporting skills development through initiatives such as the Data Science Institute at the University of Exeter, with joint academic appointments and projects, as well as supporting the proposed South West Institute of Technology. The Met Office is also supporting a number of national bids for doctoral training programmes on data science for UKRI (NERC and EPSRC).

With regard to career prospects and attracting students to the relevant disciplines, there could be benefit from doing more to show how geospatial skills can underpin a variety of roles across many organisations and industries, reflecting the practical need for blended skills and the application of specialised skills to a range of areas.

It is also important to recognise that the academic route is not the only way to develop skills and we have found significant value in offering alternative career and skills development pathways through the introduction of apprenticeships and trainee programmes.

An important aspect of geospatial skills development to also recognise the value which comes from having a breadth of knowledge and encourage students or staff to develop that. Extracting value from Geospatial data and technology can be achieved in a variety of ways including combining information from a variety of sources and disciplines to generate new insight. Ideal geospatial skills will be underpinned by Mathematics, supported by domain knowledge of the data sets being aligned, compared or analysed. In technological and scientific career paths, a *depth* of understanding is often more valued than a *breadth* of knowledge; such as a combining applied science, statistics and technology. This is a systematic issue that could be addressed by creating a culture that rewards multiple domain experience.

Finally, it is widely recognised but important still to note – and take action on the fact – that to increase skills in Science, Technology Engineering and Mathematics

(STEM) areas it is vital to engage children at early stages of their education and build a connection with these subjects. The Met Office works with young people across the country to build interest in STEM careers for example. This is done through our wide-ranging programme of outreach which aims to engage young people in Met Office science and technology (and STEM more generally), encourage interest in STEM careers, raise awareness of the varied work of the Met Office and to share our science. Similar programmes could be used to engage young people in other geospatial skills, through highlighting the varied careers that development of such skills can offer.

Q3. What are the geospatial skills needs and gaps in your organisations, how can these be most effectively addressed, and how can careers in the sector be best promoted?

The Met Office, in common with many other employers, is finding it increasingly challenging to recruit data science and analysis skills – particularly those at the mid-career and senior levels where technical understanding is combined with broader experience and management skills. This is due to a combination of factors including increased demand for these skills across the economy; the challenges of recruiting outside of London and the South East (even when we are located within an emerging cluster of excellence); and the challenges of public organisations competing with private sector pay levels, particularly at senior levels.

There are some positive developments – suitable courses are starting to emerge as colleges and universities, including those in Exeter and the South West, recognise the demand. The Met Office is encouraging this through its support for the proposed South West Institute of Technology led by Exeter University and involving other Universities, 6th form colleges and Higher Education institutions in the region. This will join up existing activities as part of a more ambitious objective to develop a skills escalator for technical skills in the region from 6th form through to degree level and improved employment and business development in the region. We are also encouraged to see high profile investments such as the Turing Institute which are starting to address the skills issue at the top levels of research and doctoral training.

Additionally, as part of the Government Science and Engineering network, we support the development of the Geography profession within the GSE network which includes a focus on geospatial skills. This new profession intends to offer staff networking opportunities across government and learning and development opportunities. In addition, networks such as the Government Geography profession could also facilitate secondments across like-minded organisations to allow staff to develop their skills and apply them to a range of problems throughout their career.

Q4. Are there any publicly or privately-held geospatial datasets that are currently challenging to access or use or of insufficient quality, but which you or your organisation would find valuable if these issues could be resolved? Please explain why this would be of value, and how access/quality could be improved?

The Met Office and our customers are increasingly interested in data which can help us to understand risk, of which the hazard is only one component. We have good access to geospatial hazard data for weather and climate hazards, however the data covering exposure and vulnerability can prove more difficult for us to access. The specific Geospatial datasets which we need depend on the question being asked, however they often relate to infrastructure (such as the location of key assets), population data or land use.

We have found that poor curation of data significantly impedes its use, particularly when that use is for purposes other than that for which the data were originally collected, especially where GDPR requirements may come in to play. This was also noted in the Treasury discussion paper on *The Economic Value of Data* (link) which highlighted that the potential value of data may not always be foreseeable to the data creator or controller. Data about risk exposure or vulnerability is often collected with little or no geospatial data, which limits the extent to which it can be reused to generate additional benefit. Encouraging the inclusion of geospatial data and high quality metadata in more datasets would help to unlock additional synergies and generate new information and services.

For example the Met Office are currently working with Highways England to compare road data with meteorological data to better understand how weather and climate impacts road conditions; however poor quality location data in the road sensor dataset has created additional work to go back and properly characterise this data. Similar issues have been experienced when working with rail and electricity network fault data. We would therefore strongly support actions to raise the general awareness about what “good” datasets look like, and efforts to meet a minimum standard to ensure reusability. This would enable the UK to get better value from the investment that goes into collecting data, and the public sector could lead by example on this.

Q5: Do you anticipate that any changes will be needed to the both address data and the wider address ecosystem, to support emerging technologies? Please provide evidence of value to support any proposed changes.

The Met Office don’t tend to use addressing data in this way. Meteorology isn’t just land based or even UK based and our interest is through the depth of the atmosphere and oceans, so our reference systems are based on latitude, longitude and vertical height.

Q6: How should the commission be looking to develop the UK's capability in Earth observation data, both technologically and to support an effective market?

The Met Office is a long-term user of space-based Earth Observations (EO) for meteorology and as such is an expert in the exploitation of this type of data. In meteorology and climate science, Earth Observations are considered to include both satellite observations and in-situ measurements; however, we have seen the term used to refer exclusively to space-based observations without this being specified which can cause confusion. We have provided some more information about our experience in working with satellite EO below.

The current capability in EO has been developed through long-term international collaboration as it is difficult for any single nation to provide both the broad range of skills and the high level of funding required. This model works well as there is a common base requirement both across Europe and internationally. Continuing engagement with the international community will be vital to maintaining and developing the UK's EO capability.

At present the UK's use of EO data and engagement with EO data providers is led by expert users, often in a narrow context related to their specific requirements. More value could be unlocked from this data by building on the good work already done and creating a common access model for Government and non-government stakeholders. Such an access model should have inter-departmental sharing of data for the public good at its heart, and work in collaboration with existing users to ensure that current access and expertise is not diminished.

Importantly, in creating an 'effective market', a balance needs to be found which encourages the free sharing of data without diminishing its financial value. While the private sector can provide innovative and effective approaches to EO data; partnerships between the public and private sector need to ensure that contracts do not prevent the re-sharing of data between public bodies for safety critical services and the public good. Best practice in data standards and licencing can be used to ensure that the value of such data is maximised.

The provision of data as a service must be affordable to users, which will require careful consideration of the business models used. Such data services need to provide data of a consistent quality; with robust, traceable and transparent information on the data – including about data collection, creation or processing – being available to ensure this. Our work in using EO to understand climate change, has highlighted the need for such metadata to provide a consistent record in order to maintain the quality of our climate records. We would be happy to discuss these challenges further with the Commission if this would be helpful.

In the Met Office we have found that assimilating basic data (such as satellite radiances) directly in our Numerical Weather Prediction model is an efficient way of establishing the atmospheric state as a starting point for predicting its future development and leads to improved forecast products. So we tend to work with this basic data rather than processed data (such as atmospheric temperature profiles). This approach also provides us with more control over the data

processing, so we know about any changes to the data immediately and can react accordingly. Provision of data from novel EO suppliers should build on this expertise, and include partnership working to maximise the value extracted from their EO data.

Q7. Which new technologies should the commission focus on to provide new opportunities to process and exploit geospatial data for economic growth?

When considering the use of new technologies consideration should be given to the interoperability of various technological platforms, through the use of tried and tested platforms and standards such as those developed by the Open Geospatial Consortium (OGC).

While new technology will undoubtedly unlock further innovation, there are still significant benefits to be unlocked by making existing proven technology work for all and this opportunity shouldn't be missed by focussing just on new technologies.

Q8. How can geospatial data and applications be used to support enhanced roll-out of future technologies?

Autonomous vehicles are one future technology with a significant requirement for geospatial data and we outline some examples of how such data can be used to support the roll out of this technology below. Similar considerations are likely to apply when considering the geospatial data requirements of other future technologies.

Autonomous vehicles will likely require a diverse range of data and information, which may be rapidly changing over hours or even minutes (such as meteorological observations and predictions) in order to deliver maximum benefits. Agreed standards of data interoperability will help to ensure that data can be exploited by a range of users, thus maximising the benefits of such data.

The information available to such vehicles will likely be coming from a range of sources and for example could include near real-time observations of hazards from other vehicles, and predictions of potential risk; the limitations of such data and information (e.g. how long ago hazardous conditions were reported, or the confidence of a prediction) should be considered and included in the decision-making systems which use them.

Use of interoperable data standards would also enable the reuse of data from

such vehicles for other purposed. For example the Met Office use MODE-S data from aircraft to provide us with additional atmospheric temperature and wind measurements, and similar data from other vehicles could provide valuable information; for example about urban meteorology and air quality.

The data infrastructure that is required to support the autonomous vehicle network will need to be capable of assimilating and processing vast amounts of data within seconds (or less) to enable all vehicles to rapidly respond to changing environmental conditions. As such, investment and innovation in transmission, processing and the quality of the data itself may also be required. In order to manage the data volumes required by future technologies such as autonomous vehicles there is also a need to have 'intelligent customers', and dialogue with data providers, so that requirements and limitations can be understood. This will allow the most relevant data to be shared with the right users at the right time, maximising the use of available data transmission and on-board processing capabilities.

Q9: What are the options for how public sector organisations could continue to invest in maintaining and enhancing our geospatial data assets?

The Met Office agrees with the points made by the National Geospatial Commission about the need for business models which maximise the opportunity for users to gain value from the data, while also supporting the sustainable and up-to-date development of their geospatial assets.

We also agree that investment decisions need to consider more than just the data assets, but also the infrastructure that supports it.

Q10: What areas of the underpinning geospatial infrastructure such as positioning technologies, including GPS and indoor positioning systems, and geodetic networks and frameworks to support them, should we be prioritising the development of, in order to support the emerging requirements for geospatial data?

Enabling users to gain value from the data requires the data to be useful and useable. To that end, data accessibility through consistent data formats, data catalogues, data licensing etc. are key aspects of the infrastructure. This aligns with the INSPIRE directive (as referenced in the Geospatial Strategy document) which establishes an infrastructure for spatial information in the EU to make spatial datasets available in a consistent format.

Q11: What role should the private sector have in both the development and maintenance of the underpinning infrastructure and enhancing the UK's geospatial data assets?

When working to support the public sector, the private sector should be encouraged to use ways of working which are compatible with data sharing and reuse for the public good. For example, updating public procurement requirements to encourage Government suppliers to adopt the use of open data standards or include agreements regarding the release of data for known and agreed purposes.

Care should be taken to understand the available private and public sector data capabilities; and avoid unnecessary duplication of capability development. The robustness of data driven decision-making tools should also be available for challenge, with a transparent approach to methodologies allowing customers to understand how decisions are being made. This approach can also enable innovation though better understanding of both customer requirements and supplier capabilities.

Maintaining geospatial data expertise in the public sector is a vital part of being an intelligent customer when developing partnerships with the private sector. The public sector will need to maintain an expert understanding of its data and the requirements for storing, moving and processing it in order to develop the most appropriate solutions for the development and maintenance of this data.

Q12. Do you face challenges when working with geospatial data from across the public sector? If so, what are they and how could value be better released? Are there any technical remedies or standards that could be adopted to improve the interoperability of geospatial data? Please provide supporting evidence of what these remedies could help to accomplish.

The Met Office has a remit to provide services to support decision-making, however there are valuable opportunities to be unlocked from combining meteorological observation data and forecast outputs with other data (from both the public and private sector). There are currently significant challenges to overcome in order to combine sources of data with a myriad of data standards, formats and legal statuses due to their origins in different organisations.

Appropriate and clear licencing of geospatial data is vital when making it available to others. Ensuring that public sector datasets have a clear licence, ideally tending towards open access and making use of existing open data standard licences would make it much easier to understand how public sector data can be reused by other public and private sector organisations.

For example the Met Office have been working with other public sector organisations to understand the possible scale of socio-economic benefits associated with enhancements to the rainfall observing networks (typically from radar and rain gauges), specifically in the context of flood mitigation. This work required access to information concerning river catchment boundaries, time to peak river flows and properties at risk in terms of flood return periods. While all required data were in existence, there was significant inefficiency in terms of access and common standards across the datasets, which could have been reduced with improved data standards and licencing.

The Met Office is part of the World Wide Web Consortium (W3C) and involved in the development its Data on the Web Best Practices. Increasing public sector engagement with such consortia would help to improve the visibility of public sector data, and help public sector organisations develop consistent standards that complement their ways of working. In addition to using international best practice for data on the web and licencing, using international standards for data quality and interoperability will also help with the sharing and reuse of public sector data. The Met Office is part of the Open Geospatial Consortium which is trying to develop standards, tools and best practices to simplify the sharing and use of geospatial data.

We have previously led initiatives with other public sector organisations to improve data access and interoperability, such as the Environmental Science to Services Partnership's DataSpring prototype which provided a single sign-on one stop shop for trusted environmental data. Members of the geospatial Commission were involved in this work and are taking the learning forward in the work they are doing on common licensing, intellectual property and access.

Q13. How can the Geospatial Commission act as a more effective customer for geospatial data on behalf of the public sector?

Q14. Are there any additional geospatial datasets, from the other partner bodies or other sources, that the public sector would derive significant benefit from having access to, that might have novel and valuable use cases? What would that access look like?

Q15: How can we best develop a single UK strategy, ensuring alignment between the individual strategies across the UK while still allowing for regional variations?

More could be done to clarify how different government data strategies and initiatives work together across the existing landscape: including local, devolved and national government, and work done in different departments. This would enable stakeholders within and beyond government to better support the UK's Geospatial aspirations.

Q16: How can we best ensure effective local authority coordination and sharing of best practise, using location data to better deliver public services?

Q17: As a result of this analysis, we are prioritising the exploration of possible initiatives in the high-value categories identified:

- **property and land**
- **infrastructure and construction**
- **mobility**
- **natural resources**
- **sales and marketing**

What are the existing or potential geospatial applications which could be scaled-up or developed in order to capture economic value? (We would particularly welcome responses from industry and other bodies engaged in these sectors.)

Meteorology has a role to play in supporting core geospatial organisations in all of these areas, particularly mobility, natural resources and sales and marketing; and the Met Office is currently working to support these sectors through a variety of geospatial services. The dynamic nature of weather predictions (which are updated every hour) mean that they need to be treated differently from the underlying geospatial data. However, when dynamically combined with other sources of dynamic or static data, e.g. from transport systems or utility infrastructure networks, they can add significant value.

Met Office work on understanding and mitigating future weather and climate risk around infrastructure and construction is currently being done in a piecemeal way, on a case by case basis, with poor data for the reasons outlined in our response to question 4. More benefits could be generated by developing a more coherent approach: through the collation of good quality infrastructure impact data from a range of sources.

Q18: Are there any other areas that we should look at as a priority?

Following on from the National Flood Resilience Review (NFRR), more could be done to understand the risk to critical national infrastructure from flooding. Plausible extreme rainfall data from the Met Office was made available through a Government Non-commercial licence for a Defra competition (more information is available here: https://consult.defra.gov.uk/water-and-flood-risk-management/flood-risk-management-modelling-competition/). More value could be unlocked from this data by combining it with data about the location of infrastructure such as mobile phone masts and electricity sub stations, to continue the work on local resilience outlined in the NFRR.

Q19: What are the main potential private and public sector innovations that will rely on the use of geospatial data to rollout, and are there corresponding regulatory challenges?

As stated in response to question 8, autonomous vehicles are one future technology with a significant requirement for geospatial data, we have outlined some of the regulatory geospatial data challenges which may arise in this area, many of which will also be applicable to other areas.

The connectivity between physical infrastructure and moving vehicles is likely to be affected by aspects such as weather conditions and topography. This effect is already being seen in testing of 5G connectivity and innovation in this area may need to be adopted to build scalable and reliable transport solutions in the UK.

The current generation of autonomous road vehicles rely upon lidar, radar and camera type sensors for various aspects of their operation. It is our experience that all can suffer either degraded performance, or even misleading output, in specific severe weather conditions. Indeed severe weather issues are often cited as one of the key obstacles in the development and adoption of autonomous vehicles. Collection of high quality metadata from such sensors could help to characterise their performance in a range of conditions, and allow variation in sensor performance to be taken into account by decision-making systems. With this in mind, consideration should be given to how regulations consider the performance of critical sensors and systems (including data transmission systems) and their ability to deliver data of sufficient quality under varying weather conditions.

Similarly, it is assumed that autonomous road vehicles will have a reliance on global satellite navigation systems such as GPS. From our position as the UK's Space Weather Operations Centre and space weather risk owner, we think it important to note the risk posed to these systems by space weather events. During a reasonable worst case event, GPS data may be degraded or completely lost for 1-3 days. There are also parts of the globe where GPS signals are interrupted on a daily basis due to space weather activity. It is not possible to improve upon the GPS technology to mitigate this risk as it is changes to the atmosphere which cause the degradation. However, governance and guidance of

use during space weather events, including the requirement for back-up systems which are not reliant on the same technology and are not susceptible to space weather, should be considered.

Q20: How best can we make the UK's presence in the international geospatial world more visible?

The Met Office have seen significant benefits from engaging in international data standards consortia such as the Open Geospatial Consortium (OGC) and World Wide Web Consortium (W3C). These allow us to contribute to the development of standards, tools and best practices which complement our ways of working; and enable the sharing of expertise from others in the international community. There are benefits to having multiple UK organisations operating in these consortia, as different public sector organisations have different concerns and priorities, and multiple UK organisations can amplify the UK's influence on issues where these organisations are aligned.

The Met Office also represents the UK in the UN's World Meteorological Organization (WMO), which sets international data standards for meteorology and hydrology, including agreements on the sharing of data between national meteorological services. Other UN organisations provide similar functions in other sectors, such as the International Oceanographic Commission (under UNESCO) and the UN Committee of Experts on Global Geospatial Information Management (UN-GGIM). The WMO has a Memorandum of Understanding with the OGC and is beginning to endorse OGC standards as part of their international regulatory framework, so we are continuing our involvement with these organisations so that we can be part of the development of data standards and best practice. Active engagement with international bodies such as the WMO can help to raise the UK's profile on the international stage.

Q21: Where should the UK be looking for points of comparison overseas? Who are the other international exemplars? What best practice is being modelled overseas that we can learn from?

Pangeo (USA and international)

The Met Office has been working in collaboration with Pangeo (http://pangeo.io/), the aim of which is to cultivate an ecosystem in which the next generation of open-source analysis tools for ocean, atmosphere and climate science can be developed, distributed, and sustained. These tools must be scalable in order to meet the current and future challenges of big data, and these solutions should leverage the existing expertise outside of the geoscience community. Rather than designing and creating a single monolithic application, Pangeo's vision is an ecosystem of tools that can be used together, by fostering collaboration around the open source scientific python ecosystem for environmental science. Amongst

other things this technology will support the development with domain-specific geoscience packages; and allow users to bring their problems to the data.

Copernicus (EU)

The EU's Copernicus programme produces very large data volumes (currently 12 Terabytes a day), which are being used by a wide range of stakeholders. To facilitate and standardise access to this data, the European Commission is funding the deployment of five cloud-based platforms providing centralised access to Copernicus data and information, as well as to processing tools. These platforms are known as the DIAS, or Data and Information Access Services. There are 5 parts to this initiative, being led by various Copernicus partners.

Geonovum (Netherlands)

Geonovum is funded by various Dutch government departments with geospatial interests, and has strong links with the private sector and academic research, such as a Technical University of Delft. The Netherlands have a balance between private sector making a profit, using open software, publicly funded infrastructure, academic research, and are not scared to take a lead in innovative issues that carry some risk, but potentially great benefit such as "Smart Cities". They are also active on the international standards front: the Co-Chair on the W3C Spatial Data on the Web Interest Group is Dutch; and they are involved in the OGC Architecture Board, providing expertise on IT security applied to geospatial.

Thank you for your time in completing your response to our call for evidence.

Any questions, please get in touch with the Geospatial Commission via geospatialcommission@cabinetoffice.gov.uk

Geospatial Commission: Call For Evidence Response Questionnaire

Please submit your completed questionnaire to:

geospatialcommission@cabinetoffice.gov.uk.

Clearly title your email *'Call for evidence response'*.

About you and your organisation

Name	[Text redacted]
Organisation	MINI MAP-MAKERS
Job title	[Text redacted]
Address	[Text redacted]
E-mail	[Text redacted]
Telephone	[Text redacted]

Please select which of the following best describes you as a respondent:

Respondent	**Please mark with a X**
Academic	
Business representative / trade body	
Central government	
Charity or social enterprise	
Individual	
Legal representative	
Local government	
Large business (over 250 staff)	
Medium business (50 to 250)	
Small business (10 to 49)	
Micro business (up to 9)	X
Other - please state	

Call for evidence - three key themes

We have identified three high-level themes that could help our approach to setting a strategy which are as follows:

1. **Supporting innovation in the geospatial sector**, exploring how to secure cutting edge skills, the right access to data, and opportunities from emerging technologies for the geospatial sector itself
2. **Enhancing the UK's geospatial assets,** looking at how best to align interests, avoid duplication, and instill best practice across the whole public sector
3. **Driving investment and productivity in geospatial applications**, asking in which wider sectors the most value lies from better exploitation and use of geospatial data, in the UK and internationally

Our questions

Q1. Is our view of the geospatial data types accurate? If not, what should be included or excluded from this?

YES - ALL GOOD BUT ITS THE TRUST ELEMENT OF THE DATA - HOW DO WE KNOW AS USERS ITS CORRECT? HOW DO YOU KNOW ITS CORRECT?

ONE CENTRAL PORTAL FOR THE DATA - MAKING SURE ITS UPDATED AND NOT REMANED EVERY OTHER MONTH - LIKE THE OLD OGA!!

Q2. In addition to current government policy, what are the areas of geospatial skills where the commission could best focus, to help ensure the necessary capability within the UK for the future?

I WORK WITH CHILDREN JUST STARTING SCHOOL - 4 YEAR OLDS WHO ARE LEARNING TO LOOK AT SHAPES, COLOURS, LETTER AND NUMBERS
THESE ARE BASICALLY WHAT MAPS ARE
SO SUPPORTING FROM THE GRASS ROOTS LEVEL WOULD BE AMAZING!
MAKING SURE I AM IN LINE WITH THE PATH THAT EVENTUALLY LEADS TO A JOB..

Q3. What are the geospatial skills needs and gaps in your organisations, how can these be most effectively addressed, and how can careers in the sector be best promoted?

I AM A PROFESSIONAL CARTOGRAPHER, GIS USER AND GEOGRAPHER

I GO INTO ALOT OF SCHOOLS- ALL AGES AND THEY DONT KNOW HOW TO MAP READ.
DO THE BASICS FIRST
ALOT OF SCHOOLS DO NOT HAVE COMPUTERS - IF THEY DO - GREAT BUT THERE IS NO INTERNET TO SUPPORT 30 STUDENTS ACCESSING THE SOFTWARE/INTERNET!
I AM TALKING TO ESRI ABOUT THIS!

Q4. Are there any publicly or privately-held geospatial datasets that are currently challenging to access or use or of insufficient quality, but which you or your organisation would find valuable if these issues could be resolved? Please explain why this would be of value, and how access/quality could be improved?

UPTO DATE HOUSE PRICES, EDUCATION NUMBERS, ENVIRONMENTAL NUMBERS/DATA, I USE ALOT OF DIFFERENT DATA TYPES - FROM ALOT OF DIFFERENT SOURCES!
SO TO REMEBER TO UPDATE EVERY MONTH - I GOT TO AT LEAST 20 SITES!

Q5: Do you anticipate that any changes will be needed to the both address data and the wider address ecosystem, to support emerging technologies? Please provide evidence of value to support any proposed changes.

DATA AND THE SOFTWARE NEEDS TO KEEP UP - THERE WILL BE A MORE NEED FOR AR AND AI AND ALL THE INFRASTRUCTURE THAT GOES WITH IT!
GO TO A GEO BUSINESS OR GEO DATA OR ESRI CONFERENCE AND YOU WILL SEE THE HUGE ADVANCE IN TECH
NOT ALL MICRO COMPANIES CAN CATCH UP / KEEP UP OR FINANCIALLY KEEP UP AND BE COMPETITIVE!

Q6: How should the commission be looking to develop the UK's capability in Earth observation data, both technologically and to support an effective market?

KEEP WITH EUROPE - DON'T REINVENT THE WHEEL - IT WOULD PUT US BEHIND AGAIN
[Text redacted]
THE OBS DATA NEEDS TO BE SHARED NOT RE MADE

Q7. Which new technologies should the commission focus on to provide new opportunities to process and exploit geospatial data for economic growth?

GEO FRAMEWORK OF DEVICES - MAKE SURE ALL THE DATA WE HAVE IS ACCURATE
AN AUDIT OF WHAT WE HAVE
WHAT DONT WE HAVE - THIS WILL THROW UP QUESTIONS ABOUT HOW WE GET THAT DATA
INFRASTRUCTURE
SECURE LOCCATIONS FOR STORAGE

Q8. How can geospatial data and applications be used to support enhanced roll-out of future technologies?

ONCE THE DATA AND TECHNOLOGIES AUDIT IS COMPLETED
OTHER QUESTIONS CAN BE ASKED AND SEE IF THEY FIT
THE FRAMEWORK - IF THEY DONT
THERES YOUR ANSWER
I THINK SCHOOLS SHOULD BE A STARTING POINT
THEY ARE SIMPLY NOT LEARNING THIS GIS OR GEOSPATIAL
STUFF AS THERES NO INFRASTRUCTURE! AND THE
TEACHERS NEED TO EMBRACE IT TOO.PROPER
SUPPORTED TRAINING FOR THEM - NOT A 2 DAY COURSE
AND OFF YOU GO.

Q9: What are the options for how public sector organisations could continue to invest in maintaining and enhancing our geospatial data assets?

THERE NEED S TO BE A PROPOER AUDITED PORTAL FOR THEIR MOST UPTO DATE INFORMATION
ACCESSABLE TO PUBLIC
SOME DATA WILL NEED TO BE AUTHORISED
AGAIN A PROPER FRAMEWORKS ORGANISATION OF WHAT IS THERE NOW

Q10: What areas of the underpinning geospatial infrastructure such as positioning technologies, including GPS and indoor positioning systems, and geodetic networks and frameworks to support them, should we be prioritising the development of, in order to support the emerging requirements for geospatial data?

WE ARE OK FOR THE OUT DOOR - DUE TO THE SATELLITES
I THINK THE INDOOR WOULD BE THE GREAT PLACE TO START
PUBLIC BUILDINGS- HOSPITALS, STATIONS
THIS WILL THROW UP QUESTIONS AND ISSUES THAT WILL BECOME A STANDARD FOR OTHER SITES.
THE BEST GPS FRAMEWORK
ASK THE YOPUNGER GENERATION WHAT THEY WANT TOO - AS THEY WILL BE MAKING/DEVELOPING /USING IT ULTIMATELY

Q11: What role should the private sector have in both the development and maintenance of the underpinning infrastructure and enhancing the UK's geospatial data assets?

DATA CONTRIBUTION
FRAMEWORK AND POLICY HELP AND SUPPORT
APPRENTICESHIPS
FUNDING TECH/TEACHING IN SCHOOLS - PROFESSIONALS INTO SCHOOLS PROGRAMME
MAKE IT PART OF JOB DESCRIPTIONS TO HELP IN LOCAL SCHOOLS AND SUPPORT TEACHERS

Q12. Do you face challenges when working with geospatial data from across the public sector? If so, what are they and how could value be better released? Are there any technical remedies or standards that could be adopted to improve the interoperability of geospatial data? Please provide supporting evidence of what these remedies could help to accomplish.

I JUST GET FRUSTRATED OF THE AGE OF IT AND ALSO IT IS COMPLETE AND ACCURATE
HOW CAN I CHECK IF THE NUMBERS/ NAMES ARE CORRECT?
I JUST HAVE TO USE IT AS IS. I AM A ONE PERSON BUSINESS SO RELY ON THE DATA BEING ACCURATE/COMPLETE
THATS WHY IF THERE WAS ONE GEOPORTAL - WHERE THEY UPLOADED THEIR MOST UPTODATE DATA FOR THE PUBLIC TO USE..
LIKE THE OIL COMPANIES WITH THE OGA - THAT WORKED REALLY WELL- I USED TO HAVE TO DO THIS! SO I MADE SURE THE DATA WAS A OK AND UPTO STANDARDS

Q13. How can the Geospatial Commission act as a more effective customer for geospatial data on behalf of the public sector?

GETTING A LIBRARY OF ALL DATA AVAILABLE IN ONE PLACE - NOT NECESSARILY THE ACTUAL DATA
BUT WHAT IS AVAILABLE IN THE UK/GB
WORKING WITH THE SCOTTISH/NI AND WALES GOVERNMENTS ON COLLABORATION OF IDEAS
TIMETABLED UPDATES FOR DATA
MAKE IT A STANDARD THAT COMPANIES CAN ADHERE TO LIKE AN ISO4001

Q14. Are there any additional geospatial datasets, from the other partner bodies or other sources, that the public sector would derive significant benefit from having access to, that might have novel and valuable use cases? What would that access look like?

YOU WOULD HAVE TO BREAK THE DATA UP INTO THEMES
BASEMAP
ENVIRONMENT
SOCIAL
ECONOMIC
ETC

Q15: How can we best ensure effective local authority coordination and sharing of best practise, using location data to better deliver public services?

MAKE IT POLICY THAT THE LAS PUT THEIR DATA IN A PORTAL THAT IS UPDATED MONTHLY - THERE ARE GIS PEOPLE THAT ARE DOING THIS NOW - MAKE IT PART OF THEIR JOB AND DEPARTMENT - THERE HAS TO BE A STANDARDS LEVEL TOO - 5 STAR ETC..
EG - PLANNING INFO IS LEGAL SO THATS UPTO DATE! OR IS IT..?

Q16: As a result of this analysis, we are prioritising the exploration of possible initiatives in the high-value categories identified:

- **property and land**
- **infrastructure and construction**
- **mobility**
- **natural resources**
- **sales and marketing**

What are the existing or potential geospatial applications which could be scaled-up or developed in order to capture economic value? (We would particularly welcome responses from industry and other bodies engaged in these sectors.)

TALK TO VERISK/GEOINFORMATION - THIS HAS BEEN DONE ALREADY BUT PEOPLE HAVE TO PAY FOR IT..
DONT WASTE TIME REINVENTING ANOTHER HOUSING LAYER..THEY WILL NEED TO PROVIDE X AMOUNT OF DATA TO YOU - OTHER DATA NEEDS TO BE PURCHASED.
INFRASTRUCTURE & CONSTRUCTION - AGAIN THE COMPANIES NEED TO GIVE YOU THE DATA AND PUT A VALUE ON THE REST.
ARE YOU HERE TO MAKE MONEY, ADVISE OR GIVE OUT FREE DATA ?

Q17: Are there any other areas that we should look at as a priority?

ENVIRONMENT
EDUCATION
HEALTH
SOCIAL

(IN NO PARTICULAR ORDER)

Q18: What are the main potential private and public sector innovations that will rely on the use of geospatial data to rollout, and are there corresponding regulatory challenges?

TALK TO THE OU IN MILTON KEYNES..
I CANT ANSWER THIS ONE!

Q19: How best can we make the UK's presence in the international geospatial world more visible?

HAVING A CLEAR CONCISE FRAMEWORK
HAVE LEGITIMATE DATA
HAVE SECURE DATA
HAVE CONCISE AND ACCURATE TIMELY DATA
HAVE A COMPLETE CATALOGUE
HAVE THE FASTEST ACCESS AND GREAT SOFTWARE AND CARTOGRAPHERS / GRAPHIC DESIGNERS TO VISUALISE THE DATA
HAVE A EXCEPTIONAL EDUCATION PROGRAMME TO ENSURE LONGEVITY

Q20: Where should the UK be looking for points of comparison overseas? Who are the other international exemplars? What best practice is being modelled overseas that we can learn from?

ANY OIL COMPANIES
NPD IN NORWAY
GEOSCIENCE AUSTRALIA
https://opendata.swiss/en/

Thank you for your time in completing your response to our call for evidence.

Any questions, please get in touch with the Geospatial Commission via geospatialcommission@cabinetoffice.gov.uk

Call for evidence - three key themes

We have identified three high-level themes that could help our approach to setting a strategy which are as follows:

1. **Supporting innovation in the geospatial sector**, exploring how to secure cutting edge skills, the right access to data, and opportunities from emerging technologies for the geospatial sector itself
2. **Enhancing the UK's geospatial assets,** looking at how best to align interests, avoid duplication, and instill best practice across the whole public sector
3. **Driving investment and productivity in geospatial applications**, asking in which wider sectors the most value lies from better exploitation and use of geospatial data, in the UK and internationally

Our questions

Q1. Is our view of the geospatial data types accurate? If not, what should be included or excluded from this?

The items listed make sense, but it is our view that Geospatial is more than landscape and built structures and extends to population, society and the geography of consumer behaviour.

Q2. In addition to current government policy, what are the areas of geospatial skills where the commission could best focus, to help ensure the necessary capability within the UK for the future?

Q3. What are the geospatial skills needs and gaps in your organisations, how can these be most effectively addressed, and how can careers in the sector be best promoted?

Skills training and careers could be promoted via recognised industry bodies.

Q4. Are there any publicly or privately-held geospatial datasets that are currently challenging to access or use or of insufficient quality, but which you or your organisation would find valuable if these issues could be resolved? Please explain why this would be of value, and how access/quality could be improved?

Open National Address File (with geospatial element)
A standard, universally recognised address list available as an open dataset would be very benenficial, particularly if supported by accurate geospatial referencing. The value of this would extend across many areas from understanding consumer movement, transport planning, resource planning, and linking these to the private sector without barriers to entry caused by different address definitions or the cost barrier of licensing.

Lookup between PAF UDPRN and UPRN
If this were available as open data it would greatly assist in supporting our public sector clients and also enable us to exploit the value of an open UPRN with co-ordinates dataset

Land Registry INSPIRE property polygons
Royalties for commercial use make this challenging to use.

Public Transport timetable data
This is currently only available in a very complex form and is very time consuming to extract and exploit. We also have issues with data quality.

Workplace population
Regularly updated estimates of worker population at a low geographic level (e.g. workplace zone) would be of a lot of value in understanding the changing demands for services in an area. Currently we only have census data from 2011, which by the time the next census is released will be at least 12 years old. The LSOA estimates from BRES are too high level and we believe not always that reliable/plausible for local analysis being based only on the BRES survey. Could the IDBR be used for this sort of application?

DVLA licence plate to postcode/OA file
For understanding shopper catchments & demographics – almost all our clients have ANPR and capture licence plates (including local councils). If you were able to code them with a geodemographic classification and map them at a non-PII level eg OA, then councils could use it for bus route planning, increasing public transport etc. Owners of shopping centres could better understand who is visiting.

Oyster Data
Data from Oyster and other regional travel card data (e.g. Nottingham has a similar system to Oyster), in order to understand trip patterns and demand for services both in transport planning and ancillary services e.g. retail.

Census workplace flow data and Census small area micro data
Easier access to these would be beneficial. Currently these datasets have limited access due to disclosure control, which differentially impacts on private sector users.

Open up PSMA data to the private sector
To create a level playing field for the private sector and allow greater collaboration with the public sector.

Q5: Do you anticipate that any changes will be needed to the both address data and the wider address ecosystem, to support emerging technologies? Please provide evidence of value to support any proposed changes.

A standard, universally recognised address file as open data in the public domain would be very benenficial, particularly if supported by accurate geospatial referencing, for linkage with other emerging datasets e.g. mobile app data.

Q6: How should the commission be looking to develop the UK's capability in Earth observation data, both technologically and to support an effective market?

Q7. Which new technologies should the commission focus on to provide new opportunities to process and exploit geospatial data for economic growth?

Q8. How can geospatial data and applications be used to support enhanced roll-out of future technologies?

Q9: What are the options for how public sector organisations could continue to invest in maintaining and enhancing our geospatial data assets?

Whilst we support the opening up of datasets we are concerned for the continued funding to maintain quality. A number of funding models may be appropriate: increased liberal access for commercial users but at a cost, “fremium”/Spotify-type model.

Improved access should not necessarily be at a cost to quality.

Q10: What areas of the underpinning geospatial infrastructure such as positioning technologies, including GPS and indoor positioning systems, and geodetic networks and frameworks to support them, should we be prioritising the development of, in order to support the emerging requirements for geospatial data?

Q11: What role should the private sector have in both the development and maintenance of the underpinning infrastructure and enhancing the UK’s geospatial data assets?

Q12. Do you face challenges when working with geospatial data from across the public sector? If so, what are they and how could value be better released? Are there any technical remedies or standards that could be adopted to improve the interoperability of geospatial data? Please provide supporting evidence of what these remedies could help to accomplish.

Q13. How can the Geospatial Commission act as a more effective customer for geospatial data on behalf of the public sector?

Q14. Are there any additional geospatial datasets, from the other partner bodies or other sources, that the public sector would derive significant benefit

from having access to, that might have novel and valuable use cases? What would that access look like?

Q15: How can we best develop a single UK strategy, ensuring alignment between the individual strategies across the UK while still allwoing for regional variations?

Q16: How can we best ensure effective local authority coordination and sharing of best practise, using location data to better deliver public services?

Q17: As a result of this analysis, we are prioritising the exploration of possible initiatives in the high-value categories identified:

- **property and land**
- **infrastructure and construction**
- **mobility**
- **natural resources**

- **sales and marketing**

What are the existing or potential geospatial applications which could be scaled-up or developed in order to capture economic value? (We would particularly welcome responses from industry and other bodies engaged in these sectors.)

Q18: Are there any other areas that we should look at as a priority?

Q19: What are the main potential private and public sector innovations that will rely on the use of geospatial data to rollout, and are there corresponding regulatory challenges?

Q20: How best can we make the UK's presence in the international geospatial world more visible?

Q21: Where should the UK be looking for points of comparison overseas? Who are the other international exemplars? What best practice is being modelled overseas that we can learn from?

Thank you for your time in completing your response to our call for evidence.

Any questions, please get in touch with the Geospatial Commission via geospatialcommission@cabinetoffice.gov.uk

Call for evidence - three key themes

We have identified three high-level themes that could help our approach to setting a strategy which are as follows:

1. **Supporting innovation in the geospatial sector**, exploring how to secure cutting edge skills, the right access to data, and opportunities from emerging technologies for the geospatial sector itself
2. **Enhancing the UK's geospatial assets,** looking at how best to align interests, avoid duplication, and instill best practice across the whole public sector
3. **Driving investment and productivity in geospatial applications**, asking in which wider sectors the most value lies from better exploitation and use of geospatial data, in the UK and internationally

Our questions

Q2. In addition to current government policy, what are the areas of geospatial skills where the commission could best focus, to help ensure the necessary capability within the UK for the future?

A key feature of working with geospatial data is that it can be joined up to any other geospatial data to create more useful and insightful analysis. Doing this on any scale requires analysis in a programming language or database software outside of COTS GUI platforms - most of which are closed source.

Skills development in this area should be understood as more than learning the skills required for particular platforms. It should take the shape of understanding principles that are broadly applicable across both open and closed systems.

New GIS startups depend (and will continue to depend) on language and framework knowledge (python/ postgis/ etc) rather than knowledge of suites such as ArcMap.

Q4. Are there any publicly or privately-held geospatial datasets that are currently challenging to access or use or of insufficient quality, but which you or your organisation would find valuable if these issues could be resolved? Please explain why this would be of value, and how access/quality could be improved?

A key problem across mySociety projects is helping people identify which administrative area they live in, to gain access to services, or identify their elected officials. One of the most common patterns used to solve this is a postcode lookup, which links someone's postcode with administrative area. OS CodePoint Open provides a free dataset that allows projects to do just this.

But postcodes do not necessarily sit neatly within administrative boundaries. Some postcodes span multiple local authorities or constituencies, meaning that software relying on postcode-to-boundary lookup will deliver the wrong results for around 70,000 households for local authorities.

The datasets that would allow civic tech projects to correctly allocate individual addresses to the correct area (AddressBase) or postcodes that cross boundaries (CodePoint Polygons) are closed datasets. The gov.uk service — which provides an 'official' citizen-to-representative matching service — has the same issue with boundaries despite free access to the relevant licences for public bodies. This reflects that open datasets can become a de facto standard through availability and ease of use.

Open licencing of the OS CodePoint Polygons and AddressBase would allow accurate identification of where an address falls, improving accuracy of civic tech and government websites.

Q5: Do you anticipate that any changes will be needed to the both address data and the wider address ecosystem, to support emerging technologies? Please provide evidence of value to support any proposed changes.

See answer to Q4

Q7. Which new technologies should the commission focus on to provide new opportunities to process and exploit geospatial data for economic growth?

The commission should focus on investment in open source tools and in the release of open datasets. New startup use of geospatial tools will be based on open source tools, open release of key geospatial datasets has a multiplier effect on the range and diversity of potential uses of the data.

Lowering the cost of entry for new services and products based on geospatial data will result in an increase in innovation that will produce a diverse range of end results.

Thank you for your time in completing your response to our call for evidence.

Any questions, please get in touch with the Geospatial Commission via geospatialcommission@cabinetoffice.gov.uk

Geospatial Commission: Call For Evidence Response Questionnaire

Please submit your completed questionnaire to:

geospatialcommission@cabinetoffice.gov.uk.

Call for evidence - three key themes

We have identified three high-level themes that could help our approach to setting a strategy which are as follows:

1. **Supporting innovation in the geospatial sector**, exploring how to secure cutting edge skills, the right access to data, and opportunities from emerging technologies for the geospatial sector itself
2. **Enhancing the UK's geospatial assets,** looking at how best to align interests, avoid duplication, and instill best practice across the whole public sector
3. **Driving investment and productivity in geospatial applications**, asking in which wider sectors the most value lies from better exploitation and use of geospatial data, in the UK and internationally

Our questions

Q1. Is our view of the geospatial data types accurate? If not, what should be included or excluded from this?

Yes, we agree with the accuracy of the geospatial data types provided.

Q2. In addition to current government policy, what are the areas of geospatial skills where the commission could best focus, to help ensure the necessary capability within the UK for the future?

We are not aware of any further areas of geospatial skills in which the commission could best focus.

Q3. What are the geospatial skills needs and gaps in your organisations, how can these be most effectively addressed, and how can careers in the sector be best promoted?

It would be valuable for estate agents to be trained in the use of Geographic Information System (GIS) mapping software, particularly for its use throughout the process of a sale and for marketing. GIS is a framework for gathering, managing and analysing geographical data, it can also be used to visualise the data – for instance, on an interactive map. Considering this, many estate agents will require training to understand geospatial procedures, workflows and software and how best to encompass this technology into their businesses.

Online courses and webinars are ideally suited to teach geospatial skills as they are both accessible and informative. The commission should consider hosting webinars for the various sectors included in this call for evidence. HM Land Registry provides webinars to understand the conveyancing process[1], which have been made freely accessible for the public on various devices. We believe the Geospatial Commission could replicate this service.

A bespoke geospatial skill course specifically for estate agents could be made available at varying levels of learning depending on demand. NAEA Propertymark offers courses for estate agents, some are online specific, and others can be location based or in-house. These are made available to both members and non-members. This course would then be advertised through our various communications such as mailers, articles, our magazine Property Professional and at events throughout the year.

The commission should consider working alongside private sector geospatial companies in offering training for businesses in geospatial skills. For example, Cadcorp[2] provides clients with the option of either a standard or bespoke training course – which can be provided on or off site. Cadcorp is used specifically in land and property for GIS land management, and has use for estate agents, property developers (such as McCarthy & Stone[3]), housing associations and lettings. Esri UK & Ireland[4] provides a 'Request a Demo' service, where those enquiring can select a date and time and make requests to tailor the demo to their needs. Esri works with both private and public sector clients such as: Knight Frank and the Greater London Authority. Bespoke training provided by private companies work well for all parties involved, encouraging relationships between the commission and the private sector and offering more choice for those who require training.

GIS maps can provide visually appealing and highly interactive marketing materials for estate agents, an example of this being OS Open Zoomstack[5]. OS Open Zoomstack is a comprehensive vector base map that shows detail of Great Britain's mapping down to street level. This technology could be utilised in virtual tour videos of properties online. It has a 'Fly to' feature that allows users to zoom in on a specified location through animation and has differing maps for day and night. An example of this could be using the night map to highlight local nightlife for those looking to buy in a quieter neighbourhood. If Zoomstack progresses beyond trial stage, estate agents would benefit from accessing the technology through a licence. Ordnance Survey should consider marketing this to the property sector by providing online demonstration and user guides.

Encouraging further knowledge of geospatial procedures, there is added benefit for NAEA Propertymark members as any courses or webinars taken part in could be logged as Continuing Professional Development (CPD), which they must

[1] https://www.gov.uk/guidance/hm-land-registry-requisitions#webinars

[2] https://www.cadcorp.com/market-sectors/land-property/

[3] https://www.cadcorp.com/files/uploads/resource-files/McCarthy-Stone-casestudy.pdf

[4] https://www.esriuk.com/en-gb/home

[5] https://www.ordnancesurvey.co.uk/business-and-government/products/os-open-zoomstack.html

participate in at least 12 hours of per year with a minimum of four hours obtained through educational events as requirement of membership[6]. NAEA Propertymark members already go above and beyond the legal requirements for estate agents[7], and we pride ourselves in being industry leaders, having geospatial skills will further the professionalism of our membership.

Finally, following the Government's announcement to regulate property agents[8], a geospatial skillset could be a requirement of being a regulated estate agent. We have long lobbied for the regulation of estate agents. Should regulation be introduced, to promote geospatial skills in estate agency - there should be an additional requirement in qualification, or at least the ability for legislation to be amended to add this requirement in the future to coincide with technological advances. This could include a basic working knowledge of using geospatial data or GIS in the sale of property and demonstrating a working knowledge of the software. This would ensure all qualified estate agents have a geospatial data skillset, thus futureproofing the sector for emerging technology.

Q4. Are there any publicly or privately-held geospatial datasets that are currently challenging to access or use or of insufficient quality, but which you or your organisation would find valuable if these issues could be resolved? Please explain why this would be of value, and how access/quality could be improved?

The digitisation process of Local Land Charges must consider technological advances as most Local Authorities are not yet incorporated. Digitised Local Land Charges at the time of writing are limited to Warwick District Council, Liverpool City Council and the City of London Corporation, with only 26 local authorities' local land charges expected to be transferred by March 2019. Thus, the digitising process is still in its infancy and data migration is projected to take up to seven years[9]. Seven years is a particularly long time in terms of both governance and technology, and the commission should consider how this data migration will work alongside any advances in technology.

Making Local Land Charges digitally accessible is valuable to estate agents and their clients as it takes away some of the need for a solicitor or licensed conveyancer carrying out the search manually. Thus, this speeds up the process as the information can be obtained much quicker digitally than when requested manually by a legal professional to the Local Authority.

Ordnance Survey should begin integrating further details already publicly available into OS Master Map to further benefit user operability. OS Master Map Topography Layer provides registered land boundaries but does not then hold layer data sets

[6] http://www.naea.co.uk/join/continuing-professional-development-cpd.aspx

[7] http://www.naea.co.uk/join.aspx

[8] https://www.gov.uk/government/news/government-to-professionalise-the-estate-agent-market

[9] https://assets.publishing.service.gov.uk/government/uploads/system/uploads/attachment_data/file/700335/Local_Land_Charges_Impact_Assessment_BIS_LR003_HMLR.pdf

for ‘Price Paid Data’, which is freely available through HM Land Registry and the Open Government Licence (OGL). Considering that OS and HM Land Registry are partner bodies with the commission, we believe this collaboration would not face any challenges in a roll-out.

Collating this data in one source is beneficial for estate agents as it can be used for marketing and advertising purposes and allows for a simpler valuation process when vendors wish to sell. It would also be beneficial for consumers, as they would be able to access housing market trends when considering whether to make an investment in a certain area.

Q5: Do you anticipate that any changes will be needed to the both address data and the wider address ecosystem, to support emerging technologies? Please provide evidence of value to support any proposed changes.

There should be a standardisation of address data across the entirety of the UK. If this is not possible, the commission should consider creating an authority or standard that can combine devolved authorities address data. It is equally important that address data is verified to ensure accuracy.

The National Address Gazetteer should be fully utilised to support emerging technologies. It is managed by Geoplace which is owned by Ordnance Survey and the Local Government Association. This combines existing Local Authority data with further data from Ordnance Survey, Valuation Office Agency and Royal Mail Postcode Address File (PAF). This also includes Scottish data through a partnership with Ordnance Survey and Scotland’s Improvement Service. It uses Ordnance Survey’s AddressBase technology to match the PAF with the Unique Property Reference Number (UPRN). Almost 400 checks are ran on each record before Geoplace accepts it onto the database, meaning that each record is of high accuracy.

The commission will have to consider how to involve Northern Ireland authorities and the corresponding data to ensure a single UK standard, as Northern Ireland address data is not covered by the National Address Gazetteer. By ensuring a standardisation of address data, wider users of geospatial data in the public and private sector will be able to match up and complement existing data with clarity.

Q6: How should the commission be looking to develop the UK’s capability in Earth observation data, both technologically and to support an effective market?

It is not applicable for us to respond to this question.

Q7. Which new technologies should the commission focus on to provide new opportunities to process and exploit geospatial data for economic growth?

The commission should focus on creating a Digital Log Book for each property that is bought and sold to speed up the buying and selling process and provide transparency and comprehensive information for all parties involved. This Log Book would be underpinned through geospatial data and information held by Land Registry (or the corresponding form of land registration outside of England and Wales).

Using geospatial data as a base this technology could go further. The Log Book should have sections for the different stages of the transaction, allowing for documentation to be uploaded from the various parties with dates for deadlines and timescales. This would be a hub for property information such as: boundary lines, flood and mining zones, historical ownership data and digital copies of home related administration such as the Energy Performance Certificate. This would allow for all parties involved to log-in and find out relevant information and ensure that they are more engaged and better informed.

Property chains can become long and complicated, and a problem at any point, such as simple as missing piece of paperwork can cause delays for all involved. An online filing system specific to each property sold would speed up the process and allow for documents to be loaded onto a central point and importantly be downloaded quickly and easily to produce documents on request. Furthermore, the conveyancing process requires information from various third parties before contracts can be exchanged. The Log Book would help to avoid delays and allow regular contact with the agent and buyer to help deal with any issues that arise.

By simplifying the home buying and selling process, a Digital Log Book would contribute to an increase in property sales, and consequently revenue obtained through churn and taxes associated in the purchase of property. To this end, less time, resources and energy from all involved parties will be put into long or failed transactions and more revenue will be generated for spending on local goods and services.

Q8. How can geospatial data and applications be used to support enhanced roll-out of future technologies?

Through the creation of a commission approved geospatial standard and corresponding applications, it will provide a firm foundation to support enhanced roll-out of future technologies.

Q9: What are the options for how public sector organisations could continue to invest in maintaining and enhancing our geospatial data assets?

It is not applicable for us to respond to this question.

Q10: What areas of the underpinning geospatial infrastructure such as positioning technologies, including GPS and indoor positioning systems, and geodetic networks and frameworks to support them, should we be prioritising the development of, in order to support the emerging requirements for geospatial data?

The commission should prioritise the development of Global Positioning System (GPS) in land planning and development to efficiently source suitable locations. GIS complements GPS, combining the systems allows planners and developers to pinpoint the best location for a particular structure. For example, planning a new block of flats close to desirable amenities, or placing a commercial building in an area lacking in much needed amenities.

GIS and GPS software can forecast future needs, making it imperative that planners consider housing for the increasing elderly population. In our Housing 2025[10] report, we discovered that whilst 1.1 million households in England and Wales are overcrowded (4.5% of total households), but 16.1 million households are under occupied (making up 69% of total households). Despite a projected 48,000 additional private retirement homes by 2022[11], there will still be a significant shortfall of property for those at retirement age as the Government continue to prioritise building family homes. It is for these reasons that planners should now prioritise homes for downsizers.

Currently, there is a lack of suitable choices for 'last-time buyers'. In 2015, Legal & General commissioned a report which found that when last time buyers are looking for a new home, the most common preferences are being close to family and friends (32%), being near their current neighbourhood (18%), having easy access to healthcare (16%) and being located near shops (10%)[12].The same report highlighted the worth of this market at £820 billion.

Through prioritising GPS in planning of retirement properties, downsizers will be provided with more choice of suitable properties. Planners will be able to consider existing amenities and transport networks, whilst considering issues such as proximity to neighbourhoods and hospitals. They will also be able to make use of the software in planning new amenities to complement new housing developments for downsizers.

[10] http://www.naea.co.uk/media/1043988/housing-2025.pdf

[11] http://www.naea.co.uk/media/1047383/autumn-budget-2018-representation-to-hm-treasury-from-naea-propertymark.pdf

[12] https://cebr.com/reports/uk-last-time-buyer-market-worth-820-billion/

This not only benefits planners by making land sourcing simpler and better targeted, but also downsizers and the wider housing market. By encouraging 'last-time buyers' to downsize, existing larger properties will become available on the market, increasing churn through property sales and taking away some of the pressure for government built affordable housing. Through prioritising the use of GPS in development, the commission are futureproofing the planning and design of property and community infrastructure.

Q11: What role should the private sector have in both the development and maintenance of the underpinning infrastructure and enhancing the UK's geospatial data assets?

The role of the private sector will be crucial in opening up its own geospatial assets and data by working collaboratively with the public sector. The commission should consider working with privately held geospatial applications to encourage innovative ideas from the private sector.

Knight Frank, an NAEA Propertymark regulated company, has an entire team dedicated to geospatial data analysis in its research body. In response to the government's 2017 Housing White Paper in which the upward extension of buildings was discussed, Knight Frank utilised geospatial data to create 'SKYWARD'[13].

The creation of SKYWARD highlights that geospatial innovation from the private sector can also be exploited by the public sector. SKYWARD uses GIS software to systematically analyse the potential of every building to be extended upwards without changing the character of the skyline.

Knight Frank analysed 3D spatial data from Ordnance Survey, and cross referenced it with data from Land registry to assess ownerships as well as Historic England data in order to filter out listed buildings[14]. Knight Frank's study found that 41,000 new dwellings could be built in Zones 1 and 2 of Central London, just through utilising roof space.

Another working example of the private sector working alongside the public sector to exploit useful geospatial data is GetRentr[15]. GetRentr tracks regulation from across the UK that has impact on the private rented sector. Our sister organisation, ARLA Propertymark[16] is in a partnership with GetRentr that provides ARLA Propertymark members with a Licensing Database. This Database collates information from Local Authorities to provide a comprehensive list of upcoming property licensing schemes and consultation events. GetRentr provides this data by working collaboratively with Geovation, Ordnance Survey and HM Land Registry.

[14] https://www.knightfrank.co.uk/blog/2017/11/15/more-than-40000-new-homes-could-be-built-on-londons-roofs

[15] https://getrentr.com/

[16] http://www.arla.co.uk/

To incentivise the private sector in the development of geospatial infrastructure, we would recommend that the commission considers allowing GIS specialists access to data that is not publicly available or licensable. The commission could also consider interoperability between the public and private sector where both parties benefit from sharing data, such as with GetRentr.

Q12. Do you face challenges when working with geospatial data from across the public sector? If so, what are they and how could value be better released? Are there any technical remedies or standards that could be adopted to improve the interoperability of geospatial data? Please provide supporting evidence of what these remedies could help to accomplish.

There needs to be a singular platform used for GIS mapping in the public sector across the UK. Geospatial data from across the public sector has many inconsistencies. Due to the fragmentation of data provided by devolved authorities, some GIS maps are full of useful layers and localised information, whereas others lack data entirely. This means that content across the UK is inconsistent, as is the software used by the Local Authorities making use of GIS maps.

A platform such as ArcGIS[17] should be adopted to marry existing geospatial data from the public sector, this would ensure consistent data mapping and a standalone form of software that is recognisable across the UK. ArcGIS allows for the creation of maps, sharing and community collaborating and is ultimately used to analyse data. The Government are already familiar with ArcGIS, as the Cabinet Office used this software to create 'Find Me Some Government Space' – the first public-facing GIS developed by the Office to improve public sector transparency[18].

We believe that through the creation of a singular platform, operability of public geospatial data will be improved. This will be achieved by removing the complications involved with different software being used for different devolved areas. By removing inconsistencies, it makes understanding GIS software simpler. This would allow those operating across the UK to navigate the data with ease

[17] https://www.esriuk.com/en-gb/arcgis/products/arcgis-online/overview

[18] https://e-pims.cabinetoffice.gov.uk/government-property-finder/Home.aspx

without having to learn how to use multiple forms of software within the public sector.

Q13. How can the Geospatial Commission act as a more effective customer for geospatial data on behalf of the public sector?

It is not applicable for us to respond to this question.

Q14. Are there any additional geospatial datasets, from the other partner bodies or other sources, that the public sector would derive significant benefit from having access to, that might have novel and valuable use cases? What would that access look like?

It is not applicable for us to respond to this question.

Q15: How can we best develop a single UK strategy, ensuring alignment between the individual strategies across the UK while still allowing for regional variations?

The partner bodies of the commission should further integrate their data and ensure data sharing from other public bodies to create an aligned and standardised strategy across the entire UK. Ordnance Survey and Coal Authority hold data for England, Scotland and Wales and HM Land Registry only for England and Wales. As aforementioned in Q5, the National Address Gazetteer only covers Great Britain. Consequently, the commission will have to consider how best to work with the corresponding devolved authorities not covered by partner bodies.

These are the further bodies that we believe the commission should consider working alongside to develop a single UK-wide strategy:

- Land Register of Scotland from Registers of Scotland
- Land Registry for Northern Ireland from Land & Property Services
- Pointer from Land & Property Services
- OSNI from Land & Property Services
- Geological Survey of Northern Ireland (GSNI)

It is imperative that all areas of the UK work together to deliver the geospatial strategy to ensure that the UK becomes a figurehead. The commission will need to consider how a singular strategy would apply to the whole of the UK when in some of the bodies there is a lack of representation. In the charter for the Geospatial Commission, it denotes that it will coordinate with the Devolved Administrations without usurping their powers or impinge on their relationships with public and private sector bodies. Thus, the commission must make consideration of how best to gain relationships with the above bodies without contradicting the charter.

The commission should take inspiration from the EU INSPIRE Directive[19] in formulating a single UK strategy. Whilst this strategy accounts for environmental spatial information, it enables the sharing of this information across public sector organisations as well as allowing public access. This model allows for regional variation but ensures a single standard that can be understood across the member states. We believe that a similar strategy would work in aligning individual strategies across the UK whilst still encouraging regional variation. An existing example of this being Stamp Duty. Stamp Duty is collected at a national level, but the housing market is made up of differing regional markets, resulting in the criteria for paying Stamp Duty being different across the four countries of the UK.

Q16: How can we best ensure effective local authority coordination and sharing of best practise, using location data to better deliver public services?

It is not applicable for us to respond to this question.

Q17: As a result of this analysis, we are prioritising the exploration of possible initiatives in the high-value categories identified:

- **property and land**
- **infrastructure and construction**
- **mobility**
- **natural resources**
- **sales and marketing**

What are the existing or potential geospatial applications which could be scaled-up or developed in order to capture economic value? (We would particularly welcome responses from industry and other bodies engaged in these sectors.)

To exploit the economic benefits of geospatial applications, broadband maps created through Office of Communications (Ofcom)[20] data and Esri marketing and business tools should be promoted for use in estate agency, to encourage property sales and simplifying decision making.

A broadband map of the UK will encourage residential and commercial property

[19] https://inspire.ec.europa.eu/

[20] https://www.ofcom.org.uk/home

sales. Data provided to the Financial Times by Ofcom[21] has been used to produce a broadband map that highlights the disparity of internet speed across Great Britain. Whilst this study highlighted how even in city centres there is issue with internet speed, this data is useful for prospective property buyers throughout the UK.

A study by broadbanddeals.co.uk indicated that 88% of respondents would be put off buying a property where there was slow or poor broadband connection, and the average homebuyer would be willing to offer an extra £6,500 on a property guaranteed to have excellent internet speed[22]. Considering this, datasets held by Ofcom are of benefit to estate agents and their clients. Scaling up this data for across the UK would aid in finding the preferential location for a prospective home buyer, speeding up decision making and the home buying process.

A broadband map will aid in the decision making of commercial buyers for businesses. In rural locations businesses often find their options for high-speed broadband prohibitive. Through identifying a location on a broadband map, commercial buyers will gain more clarity on what their requirements for broadband will be depending on location – this could mean choosing a better suited location where the business would not be required to set up their own high-speed line or being more aware of what they will have to do to achieve high internet speed.

Instead of focusing resources on attaining an adequate internet speed, businesses can focus on starting their business up from the new location straight away and direct their revenue towards hiring staff who will in turn make further contributions to the wider economy. Additionally, for businesses that set up their own internet service there is further economic benefit as they can become an Internet Service Provider (ISP) themselves. By becoming an ISP, it will encourage further buyers into the area, consequently bringing more income into the local economy and encouraging further property sales.

To enhance marketing tools and market research for estate agents, the use of GIS software should be promoted. We believe that most of these benefits currently lie within private sector applications that are optimised specifically for business.

Esri Demographics[23] is used to provide insight on the population and can thus be used to effectively target consumers as well as to source property that fits the criteria of clients. The software allows for targeted allocation of resources in marketing and takes away time from conducting in-house market research of local areas, where the GIS software collates data from many existing sources.

ArcGIS Business Analyst[24] provides users with a map-based means to segmentation. Through analysis of demographics, the map layers allow users to identify trends of specified demographics in the area. Through better allocation of marketing resources, estate agents will be able to minimise outsourced marketing

[21] https://ig.ft.com/gb-broadband-speed-map/

[22] http://www.naea.co.uk/news/august-2017/broadband-essentials/

[23] http://www.esriuk.com/arcgis-content/demographics-and-lifestyle

[24] https://www.esri.com/en-us/arcgis/products/arcgis-business-analyst/overview

as the software brings it in-house. These maps can be used to create compelling infographics to use in property sales, and to make clients more aware of the local area.

Both technologies are used extensively in real estate marketing in the United States, and we believe it would be beneficial for estate agency marketing in the UK too. Engaging and visually appealing media will encourage clients to use these agencies themselves, going some way in aiding in customer retention and loyalty where the marketing produces results.

Q18: Are there any other areas that we should look at as a priority?

We do not believe that there are any other areas that the commission should look at as a priority.

Q19: What are the main potential private and public sector innovations that will rely on the use of geospatial data to rollout, and are there corresponding regulatory challenges?

The main potential innovations that will rely on the use of geospatial data to roll out will be the Digital Log Book (discussed in Q7), and a public register of properties owned by overseas entities, which will be discussed further in this question.

Through the introduction of a property Digital Log Book, the commission needs to consider how a geospatial data rollout will correspond with General Data Protection Regulations (GDPR) and the Data Protection Act 2018[25]. Information identifying personally owned property falls under GDPR – and geospatial data in property often reflects property ownership. Therefore, we believe a digital property log book should be a log-in service, only showing details and information to those who have permission to, consequently providing a protection for the contained personal data.

GIS in property sales improves communications between estate agents and consumers regarding Consumer Protection Regulations by offering estate agents

[25] http://www.legislation.gov.uk/ukpga/2018/12/contents/enacted

simpler access to information that may influence a sale. This will impact on the Consumer Protection from Unfair Trading Regulations 2008[26] which placed more responsibility on estate agents to provide information at the point of marketing where it was traditionally a task of conveyancers. Classically, this information (such as proximity to an operating railway line) would be physically obtained and analysing existing GIS data against property proximity absorbs much of the need to conduct checks for influencing factors.

Further, we believe that by introducing a property Digital Log Book, it is an ample opportunity to go further by introducing a compulsory 'How to Buy' and 'How to Sell' guide to complement existing 'How to Rent'[27] and 'How to Lease'[28] guides produced by the Ministry of Housing, Communities & Local Government[29]. These guides could be uploaded digitally on the portal for involved parties to access, in order to explain the differing roles of estate agents, surveyors, conveyancers and mortgage advisors and what to expect of each involved party.

One of the many arguments for using geospatial data in estate agency is to make decision-making easier. Consequently, by providing many factors that could influence a sale to a customer in a singular format, estate agents will have a comprehensive list that goes above and beyond factors that may influence a property sale allowing consumers to make better informed decisions. Additionally, providing this information to consumers in the Digital Log Book will raise consumer awareness and allow them to revisit all provided information.

The commission should consider the Draft Registration of Overseas Entities Bill[30] and the data collected on overseas entities owning property in the UK. There is a need for more importance to be placed on the verification of this information and how it relates to ownership of property and land in the UK. The data must be accurate and coincide with future technological change around buying and selling property as highlighted in this document.

Q20: How best can we make the UK's presence in the international geospatial world more visible?

Geospatial organisations and dataset holders should be promoted for their services outside of the UK to further advance the UK's presence in the international geospatial world. This has already been witnessed with Ordnance Survey MasterMap being recognised as a global exemplar; UK Hydrographic Office's ADMIRALTY being used on 90% of the world's ships[31]; and the prominence of the British Geological Survey worldwide.

[26] http://www.legislation.gov.uk/uksi/2008/1277/contents/made

[27] http://www.propertymark.co.uk/advice-and-guides/renting/england.aspx

[28] https://www.gov.uk/government/publications/how-to-lease

[29] https://www.gov.uk/government/organisations/ministry-of-housing-communities-and-local-government

[30] https://assets.publishing.service.gov.uk/government/uploads/system/uploads/attachment_data/file/727915/Draft_Registration_of_Overseas_Entities.pdf

[31] https://www.admiralty.co.uk/

Through the creation of a single UK standard, the UK can highlight its presence through exemplar collaboration and organisation. Whilst in other countries there are stellar examples of geospatial datasets and applications, even the most geospatial ready state does not have a singular platform which collates the data and layers consistently across the country.

We believe that by setting a global example, the new platform will act as a template for other countries to replicate in their own geospatial policies and also provide recognition for the best of the UK's geospatial developers.

Q21: Where should the UK be looking for points of comparison overseas? Who are the other international exemplars? What best practice is being modelled overseas that we can learn from?

Although the UK is second behind only the United States for geospatial readiness, there are further exemplary models and practices in the US, Germany and Singapore.

We believe that the commission should consider existing GIS technology in the US as a basis for combining OS Mastermap with HM Land Registry Price Paid Data. In the US, GIS land mapping company GeoThinq has created real estate investment heat maps for various states such as Florida[32]. This data is made freely available and marks properties by 'sales hotspots' and 'investment opportunity' through prices per square foot. The map also has an optional layer for commercial sales transactions. Users can choose what layers to apply to the map, which is useful for both potential investors for conducting their own research, and also real estate agents in attaining data visualisation for marketing purposes. In the UK, online property portal Zoopla has an existing GIS map with some of these factors[33], however it is in a simplified format.

The commission should consider creating a similar GIS API to privately owned TaxNetUSA[34]. TaxNetUSA is a licensed property information geospatial software that allows users to search for specifics in property and land. Users can discover property value, property equity, view floorplans and refine the search to only include owner occupied property. It is a useful tool for the real estate market as it allows in depth segmentation in marketing, down to the year the property was built and the year the owner took out their mortgage.

TaxNetUSA makes the full names of homeowners and their full addresses publicly available to view. This leaves homeowners open to receiving spam correspondence from any business or person who has searched the geospatial data in their area. In the EU such publicly available identifiable data has potential to breach GDPR, so although the software would be beneficial to replicate in the UK, the commission may need to consider the ethics behind such data and the consent of land owners.

[32] https://app.geothinq.com/

[33] https://www.zoopla.co.uk/heatmaps/

[34] https://www.taxnetusa.com/

Germany was ranked third for geospatial readiness, scoring slightly less than the UK. Since 2012 Germany has had in place legislation that allows all federal government spatial datasets, services and metadata available free of charge for both commercial and non-commercial use and reuse.

In the initial roll-out of geospatial data, the commission should consider replicating the German model of making publicly-held spatial datasets free to access and reuse. This would encourage sectors to make use of the data, and after an initial period – the commission could consider introducing fees for the services, allowing for reinvestment and upkeep of the public geospatial data. With this, users should have to option to garner additional information from privately held geospatial datasets through a generalised licensing agreement (either with full access or pay per click). Whilst in the UK there is a plethora of geospatial data held centrally, it is not necessarily open or accessible for third parties, adapting the German model will remedy this.

The partner bodies should work together taking inspiration from the Singapore Land Authority (SLA)[35], and create a singular portal that integrates various elements from the commission's partner bodies. Singapore is rated fourth on the Geospatial Readiness Index. The SLA combined the Land Office, Singapore Land Registry, Survey Department and Land Systems Support Unit and was formed in 2001. The SLA focuses on optimising state land resources for economic and social development, working alongside the Government in developing geospatial policies. Multiple disciplines come together to generate new ideas, insuring that geospatial policy is not insular to one industry. It provides various e-services, but notably an online portal where users can search and purchase land information such as property ownership, survey plans and road line plans. Along with the digitisation of the UK's land registration, the commission should consider integrating purchase features of state land in with Price Paid Data and Local Land Charges. A singular public sector portal aids in removing user confusion and increases operability.

Thank you for your time in completing your response to our call for evidence.

Any questions, please get in touch with the Geospatial Commission via geospatialcommission@cabinetoffice.gov.uk

[35] https://www.sla.gov.sg/

Geospatial Commission: Call For Evidence Response Questionnaire

Please submit your completed questionnaire to:

geospatialcommission@cabinetoffice.gov.uk.

Clearly title your email *'Call for evidence response'*.

About you and your organisation

Name	[Text redacted]
Organisation	National Centre for Earth Observation
Job title	[Text redacted]
Address	[Text redacted]
E-mail	[Text redacted]
Telephone	[Text redacted]

Please select which of the following best describes you as a respondent:

Respondent	**Please mark with a X**
Academic	**X**
Business representative / trade body	
Central government	
Charity or social enterprise	
Individual	
Legal representative	

Local government	
Large business (over 250 staff)	
Medium business (50 to 250)	
Small business (10 to 49)	
Micro business (up to 9)	
Other - please state	**The National Centre for Earth Observation is a research centre of UKRI-NERC**

Call for evidence - three key themes

We have identified three high-level themes that could help our approach to setting a strategy which are as follows:

1. **Supporting innovation in the geospatial sector**, exploring how to secure cutting edge skills, the right access to data, and opportunities from emerging technologies for the geospatial sector itself
2. **Enhancing the UK's geospatial assets,** looking at how best to align interests, avoid duplication, and instill best practice across the whole public sector
3. **Driving investment and productivity in geospatial applications**, asking in which wider sectors the most value lies from better exploitation and use of geospatial data, in the UK and internationally

Our questions

Q1. Is our view of the geospatial data types accurate? If not, what should be included or excluded from this?

The definition of geospatial data types should not be constrained artificially – all data and information types which encompass “geospatial” AND “public sector” should be included for consideration by the Commission. This includes where:

- Public sector expert organisations collect, produce and curate products and provide services, (e.g. 6 Partner bodies; UKRI-NERC Centres such as NCEO, CEH, NCAS, NOC, BAS, BGS; Met Office etc.)
- The public sector is a user of geospatial products and services and would benefit from cross government arrangements, eg for cost effective purchase of services (eg AirPhotoGB, Public Sector Mapping Agreement)
- Government policy has a strong influence on the collection and curation of geospatial data, for example with respect to satellite Earth observation (EO) data.

We particularly welcome the frequent mention of satellite Earth observation data in the consultation document. At the simplest level these are additional sources of geospatial data and information but with some special attributes, including frequent wide area update, global long term comparability and the addition of a wealth of environmental information (e.g. on condition of land cover, temperature, crop health, water quality, atmospheric gases and aerosols etc). Brought together with the products and services already provided by the 6 partner bodies, satellite Earth observation enables a much wider range of products and services for government and in support of innovation in the private sector.

It is particularly important to realise that there is a vast amount of geospatial data produced by non-GC bodies. Bringing together GC partners with non-GC partners is essential for covering geospatial data types needed by the markets.

Q2. In addition to current government policy, what are the areas of geospatial skills where the commission could best focus, to help ensure the necessary capability within the UK for the future?

Innovation will come from bringing different data sets together and using them in novel ways.

- Encourage multidisciplinary teams, eg, geographers, data scientists, statisticians, ecologicals,physical scientists and mathematicians working together.
- Develop algorithms for data fusion, change detection
- Develop understanding of data quality.
- Enhancing digital skills including software, high performance computing and AI
- Skills in transformational geospatial techniques including satellite EO and new mobile sensors.

It is noticeable that UKRI is missing from the document. Working wth UKRI and the HEI section must be an essential component of any skills strategy; UKRI invests heavily in environmental science data sets through NERC and AI through EPSRC and other councils.

It is worth emphasizing the point that whilst geography must be a fundamental discipline, there are large efforts on-going in physical sciences and mathematics capabilities applied to geospatial data. This includes new sensor technologies, for example related to autonomous vehicles and UAVs.

Q3. What are the geospatial skills needs and gaps in your organisations, how can these be most effectively addressed, and how can careers in the sector be best promoted?

In our organisation, the key skills needed are in physics, analytical mathematics and modelling, and high performance computing. The gaps are in location-based geography, high spatial resolution data processing and in links across geospatial technologies.
These gaps can be addressed by increased support of the HEI sector, by closer engagement with UKRI funding streams and by improved access to O/S type data.
A key area which needs to be addressed to accelerate progress in the geospatial sector is to attract highly skilled data scientists, mathematicians and statisticians enabling multidisciplinary teams to work together on a wide variety of problems in different types of organisations. The formation of UKRI should help to break down disciplinary barriers in research and innovation. A key area seems to be the support of HEI courses with requisite skills in geography, sensor technologies, mathematics, statistics and physics. It is not clear that the GC has considered this element.
Challenges, opportunities and careers need to be promoted in learned societies across disciplines, eg promote geography to data scientists and mathematicians and vice versa.
Ultimately people choose careers where there are jobs to go to with good pay and conditions. Does Geospatial Commission have a target in terms of new jobs created? £6-11bn for the UK economy means significant numbers of new jobs or retrained people.

Q4. Are there any publicly or privately-held geospatial datasets that are currently challenging to access or use or of insufficient quality, but which you or your organisation would find valuable if these issues could be resolved? Please explain why this would be of value, and how access/quality could be improved?

There are two key areas: 1) access and 2) a collaborative ecosystem.
Data.gov.uk is addressing some questions of access but inevitably challenges remain, even where data and information products have been paid for by public organisations - licences, particularly for commercial or operational use mean some datasets are effectively invisible or, at best under utilised.
The integration of satellite Earth observation data remains a challenge: data suppliers span both the public and private sector. In the public sector, data sources are linked to international programmes, eg Copernicus where UK may have limited influence in the future due to BREXIT. Private sector supply is often expensive for initial feasibility studies, inhibiting innovation. In both cases government could act to improve data access. Simple moves could be transformational.
One of the key attributes of satellite data is long term data availability making

them suitable for detection and attribution of change – both detecting presence/absence of features (eg trees, water) and also looking at quality of landscape. Challenges are those associated with many big data sources – efficient and effective manipulation and processing – cloud based techniques, data cubes and the like offer potential but assembly of data sets in a suitable form for easy use is still a challenge.
Collaboration in the geospatial sector needs to cross the spatial dimension from the very fine spatial resolution to the coarser-scale scientific climate product. Techniques used to extract information in the environmental sector, including models, do not necessarily have analogues in the geospatial sector and this could hinder returns on investment.
Access to datasets such as OS MasterMap should not only be made available but taught to students and actively promoted to researchers.

Q5: Do you anticipate that any changes will be needed to the both address data and the wider address ecosystem, to support emerging technologies? Please provide evidence of value to support any proposed changes.

Isolated and invisible datasets are more difficult to use than visible and easily accessible. If we want to truly exploit public investment in data then we must tend towards the latter rather than the former. This will require constructive change to achieve what is necessary.

The Commission cannot cover everything within its own team so two aspects could be very important. Firstly, ensuring key relationships are in place across government and the research centre world. Secondly, working with the other big government data initiatives would be cost-effective and bring critical mass: initiatives around space data led by Innovate UK and involving the UK Space Agency and the digital environment run by NERC. Thirdly, looking for projects between the partner bodies and other organisations that can exploit joint datasets (and models) in a synergistic manner.

Q6: How should the commission be looking to develop the UK's capability in Earth observation data, both technologically and to support an effective market?

The integration of Earth observation, where it is cost effective to do so, will be a key innovation step for the Commission. EO will augment more traditional geospatial data sources, providing new data layers, with frequent and wide area updates. Development of machine learning techniques will enable change to be tracked across the landscape, atmosphere and ocean areas of interest to the UK. For the public sector, examining change in key policy areas will provide evidence of where policy intervention is required and enable the effectiveness of policy to be assessed. Change could be on the timescale of hours (eg monitoring flooding) to years (eg monitoring the effectiveness of the 25 Year Environment Plan or the environmental impact of new road and rail infrastructure). Within this role, co-

ordination with the UK Space Agency, other government departments such as Defra and NERC will be essential.
First and foremost the Commission should provide the oversight of integrated UK government requirement for EO data and services with the objective of developing a government EO service served by appropriate satellites with routes to integration with non-satellite data assets and services.
Secondly, it should ensure that the UK has access to assets to deliver satellite-based EO data at requisite timeliness, coverage and quality.
At present a government EO service does not exist leading to fragmented activities related to individual requirements, a lack of use of skills and infrastructures already available and limited opportunity to provide transformational approaches better meeting government functionalities. The Commission should work with other stakeholders, particularly UK Space Agency, the Commission Partners and others across government and the research sector to articulate how government EO requirements are to be met.

- The commission should consider the whole value chain from satellites to identifying products and services to meet government needs. It should work pro-actively with government customers to mainstream EO data, through innovation, within the wider context of geospatial data.
- It should work with researchers and innovators to understand gaps between requirements and state-of-the-art. It should commission research and innovation projects to close the gap between current capabilities and government needs.
- It should make recommendations for EO data infrastructure to meet government needs, looking at both public sector and private sector data supply chains.
- It should set its recommendations in the wider context of innovation worldwide, both drawing on the best examples across the globe and helping to promote UK capabilities across the world. This wider dialogue will be important to support the UK geospatial industry develop markets.

An important issue going forward will be the architecture, implementation and governance of an operational government EO service. It is too early to say with confidence what this should look like but the Commission should be a key enabler. Cost effectiveness (eg eliminating duplication) and innovation should be key criteria for determining its recommendations.
The Commission should have a clear understanding that data is produced by sensors, whether on the ground or in space, and therefore geospatial data and markets are bound to sustainable and evolving observation technologies.

Q7. Which new technologies should the commission focus on to provide new opportunities to process and exploit geospatial data for economic growth?

Satellite EO is an important technology, emerging rapidly from the research domain into operational services. Other technologies worth considering are for examples use of drones, mobile sensors on all transport vehicles and HAPS. Citizen science also provides a new dimension.
With respect to data processing the consultation document mentions are wide range of techniques and technologies: AI, machine learning, analysis ready data cubes – consideration of all will be valuable to make the most of the data collected and exploited by government. Methods to provide robust data fusion, understanding uncertainties in the data and processing in the cloud are all relevant.

Q8. How can geospatial data and applications be used to support enhanced roll-out of future technologies?

The Commission should work with researchers and innovators to understand gaps between requirements and state-of-the-art. It should commission research and innovation projects to close the gap between current capabilities and government needs. UKRI has a Strategic Priorities Fund for which the GC and NERC would be obvious partners.

Q9: What are the options for how public sector organisations could continue to invest in maintaining and enhancing our geospatial data assets?

The government has at its disposal a wide range of business models and investment strategies depending on its primary objectives. A key decision point will be what the government will pay for itself and make available as free and open assets and how innovators will use these to develop opportunities in the geospatial applications. The evidence suggests that making basic geospatial data freely available drives innovation, for example making the Landsat archive available as free and open data or Google maps. Closer to home, there is good evidence from Environment Agency that making the Lidar data archive open access has created a significant increase in the number of users.
So the options which realistically lead to a increased marketplace are:

1) Free and open access with large numbers of users and a government-provided highway for UK PLC.
2) Free and open access for R&D in HEIs and businesses with streamlined access “at cost” for bespoke commercial services.

Q10: What areas of the underpinning geospatial infrastructure such as positioning technologies, including GPS and indoor positioning systems, and geodetic networks and frameworks to support them, should we be prioritising the development of, in order to support the emerging requirements for geospatial data?

Recently concerns have emerged regarding our participation in the Galileo GNSS programme. It will be unfortunate if the UK has no part to pay in this important European programme.
It is important also to recognise the geospatial infrastructure now includes:

- The observing systems including satellites and mobile “on-ground and inflight” systems
- Systems for integrating positional information
- The data processing systems wich transform raw observations to information products
- The platforms for data access, analytics and archiving.

Q11: What role should the private sector have in both the development and maintenance of the underpinning infrastructure and enhancing the UK’s geospatial data assets?

The private sector should be involved throughout the value chain from data collection systems, including new satellites through observation systems such as satellites, data curation and processing to provision of products and services.
The role of the private sector will be an important consideration if the aim is to drive innovation and growth in the geospatial economy. The private sector could divide into two camps. Those on the “inside”, working as contractors to specify, develop and provide underpinning infrastructure and enhanced geospatial data assets of the 6 partner organisations and those of the “outside” who are looking to use the geospatial assets to address new markets and provide new services, generating revenue and profit and realising the large markets foreseen in the consultation document. There will also be tensions with the partner organisations themselves; what should be done “in-house” or “outsourced” to the private sector? Where do the partners’ expertise lie and where are the other centres of expertise or evolving capabilities.
The checks and balances between what is done by the public and private sectors and the role of research organisations will need to be carefully monitored in the initial stages of development.

Q12. Do you face challenges when working with geospatial data from across the public sector? If so, what are they and how could value be better released? Are there any technical remedies or standards that could be adopted to

improve the interoperability of geospatial data? Please provide supporting evidence of what these remedies could help to accomplish.

As a research organisation, NCEO can generally get the data it needs to carry out research and development, albeit very inefficiently at times. It is not always clear what is available and what isn't; conditions for R&D are not always clear. Also data quality is not always addressed so how does a MasterMap compare to other digital elevation models? In general we have the skill sets to overcome lack of standards if needs be, but more telling for us is the lack of obvious training and engagement between different communities. Joint projects would start to overcome these barriers.
The really difficult problems come when trying to make the results of the R&D into sustainable long term services. The issues are well documented in the world of satellite data:, eg no long term guarantees of data supply; poor data access; lack of facilities to undertake big data analytics cost effectively. Some of these issues are being tackled by programmes like Copernicus – however at the time of writing BREXIT has resulted in significant uncertainty.
Depending on the breadth that the Commission needs to cover, support to build connecting digital infrastructure would be helpful. Common computing platforms and shared projects would enable new problem solving approaches with real potential for translation to the commercial sector. UKRI-NERC is working quite strongly on a new digital environment piece to which the Commission could link very nicely. In addition, organisations such as the Satellite Applications Catapult and the Defra EO Centre of Excellence have much experience and collaboration to offer.

Q13. How can the Geospatial Commission act as a more effective customer for geospatial data on behalf of the public sector?

Acting as an effective customer for geospatial data on behalf of the public sector is a very important role for the Commission. The Commission should provide the oversight geospatial requirements and ensure that the public sector is aware of what is available and what can be accessed in an efficient and transformative manner. There are some good examples already of collective thinking across government, eg PMSA and AirPhotosGB. In the area of satellite data some attempts have been made to identify value and understand requirements but much more needs to be done to be enable effective new government systems to be developed and implemented.

Q14. Are there any additional geospatial datasets, from the other partner bodies or other sources, that the public sector would derive significant benefit from having access to, that might have novel and valuable use cases? What would that access look like?

As NCEO, we are particularly interested in access routes to satellite Earth observation data, from both public and private sources. The attributes and potential value of EO data were noted in Q6.
The UK public sector holds a wide range of geospatial data, much of it open with its existence made known through data.gov.uk.
At NCEO, we also create data sets, mostly global and lower spatial resolution (typically a few hundred metres to several km), but increasingly paying particular attention to the UK. At this spatial resolution, there is a whole stream of sophisticated data products that inform UK bodies of current state from weather forcasting to climate change and ocean biology.

Q15: How can we best develop a single UK strategy, ensuring alignment between the individual strategies across the UK while still allwoing for regional variations?

Firstly, dialogue and inclusion are the best approach. If relevant regional organisations are involved for the start, they are likely to be more cooperative. In addition, it is less likely that the strategy will be problematic because it does not recognise the factors that underpin regional variations.
Secondly, use the key government bodies and national research entities to inform the GC on areas where it has less expertise. The NERC community has long-standing activities in the geospatial area and in centres it has operational expertise. NCEO provides a championing role for expert research in EO systems in the UK, working alongside many bodies including the other NERC research centres such as BGS and the Satellite Applications Catapult. We recently held the national EO conference in Birmingham with the Remote Sensing and Photogrammetry Society and the Centre for Earth Observation Instrumentation. Over 250 people attended from academia, government and industry.
Thirdly, recognise that geospatial is a technical area which is evolving internationally. Access to good technical advice is crucial which will mean going outside the six partner bodies.

Q16: How can we best ensure effective local authority coordination and sharing of best practise, using location data to better deliver public services?

This is a difficult area. Clearly working with local government co-ordination bodies is one route. A second route could be to work through local enterprise partnerships which , although focussed on business, convey a clear sense of the priorities of local leaders.

Q17: As a result of this analysis, we are prioritising the exploration of possible initiatives in the high-value categories identified:

- **property and land**
- **infrastructure and construction**
- **mobility**
- **natural resources**
- **sales and marketing**

What are the existing or potential geospatial applications which could be scaled-up or developed in order to capture economic value? (We would particularly welcome responses from industry and other bodies engaged in these sectors.)

As a research organisation NCEO is not offering a response to this question.

Q18: Are there any other areas that we should look at as a priority?

This depends on the remit that the Commission is going to adopt. Entirely reasonably, the Commission is concentrating on issues within the purview of the partner bodies but then it will need to be transparent about this. It cannot then be following a mandate to be prioritising for UK government as a whole or indeed to be international as opposed to national. This is a not a problem per se as long as there is clarity.

There are a whole raft of issues which GC could support which are being handled by other government departments but where government systems for geospatial data could help. A few examples:

Climate adaptation and mitigation. For example, there is an active Space4Climate group which is looking at market applications of climate data and working with government to unlock value from such data.

Agriculture and food security. Defra is responsible for this within the UK but of course the UK depends on both access in the UK and internationally. Co-ordination between national and international efforts is lacking.

Coastal and maritime applications. Defra, Cefas, the National Oceanography Centre and Plymouth Marine Laboratory are engaged in such work. I am not aware of the interactions with UK Hydrographic Office, however this is likely to be a big area for the UK in the future.

Q19: What are the main potential private and public sector innovations that will rely on the use of geospatial data to rollout, and are there corresponding regulatory challenges?

There is a long list of potential examples, “new space” EO satellites, drones, autonomous vehicles, precision agriculture, city planning and environmental impact assessment. Brexit clearly will increase the regulatory challenge as recognised by Defra, for example, but there are many other areas from transport to energy.

Q20: How best can we make the UK’s presence in the international geospatial world more visible?

Firstly it is essential to make the UK’s presence visible in the international geospatial world:

- to learn from the international community
- to influence international standards
- to export our know-how, products and services into global markets.

The consultation document provides some examples.
There are a number international bodies of relevance, including UN and intergovernmental organisations, eg GEO, CEOS, UN-GGIM, OGC, etc which provide UK good access to the world community and enable peer-to-peer dialogue.
The Commission should also consider how it makes its presence felt in international **user** communities.

Q21: Where should the UK be looking for points of comparison overseas? Who are the other international exemplars? What best practice is being modelled overseas that we can learn from?

A good point to start is to analyse those active /leaders in the international community, eg Geosciences Australia and their data cube.
For benchmarking it is useful to compare with countries of similar size/GDP and see how they organise geospatial data. It may be useful to take a few examples which span radically different approaches.

Geospatial Commission: Call For Evidence Response Questionnaire

Please submit your completed questionnaire to:

geospatialcommission@cabinetoffice.gov.uk.

Clearly title your email *'Call for evidence response'*.

About you and your organisation

Name	[Text redacted]
Organisation	National Oceanography Centre
Job title	[Text redacted]
Address	[Text redacted]
E-mail	[Text redacted]
Telephone	[Text redacted]

Please select which of the following best describes you as a respondent:

Respondent	**Please mark with a X**
Academic	
Business representative / trade body	
Central government	
Charity or social enterprise	
Individual	
Legal representative	
Local government	
Large business (over 250 staff)	
Medium business (50 to 250)	
Small business (10 to 49)	
Micro business (up to 9)	
Other - please state	**Non departmental Government organisation**

Call for evidence - three key themes

We have identified three high-level themes that could help our approach to setting a strategy which are as follows:

1. **Supporting innovation in the geospatial sector**, exploring how to secure cutting edge skills, the right access to data, and opportunities from emerging technologies for the geospatial sector itself
2. **Enhancing the UK's geospatial assets,** looking at how best to align interests, avoid duplication, and instill best practice across the whole public sector
3. **Driving investment and productivity in geospatial applications**, asking in which wider sectors the most value lies from better exploitation and use of geospatial data, in the UK and internationally

Introduction: Marine data management in the UK

The National Oceanography Centre (NOC) is the UK's centre of excellence for oceanographic sciences, with a remit to provide marine national capability and leadership for big ocean science at a global scale. NOC welcomes this initative to develop a National Geospatial Strategy.

NOC hosts the Marine Environmental Data and Information Network (MEDIN), which is a partnership of UK organisations committed to improving access to UK marine data and sponsored by 14 organisations, including the Natural Environment Research Council (NERC) and the UK Hydrographic Office (UKHO). MEDIN will submit a separate response to this call.

MEDIN effectively delivers marine data through a *network* of accredited Data Archive Centres (DACs). The British Oceanographic Data Centre (BODC) is the UK's designated DAC for water column oceanography, and is part of NOC. Although UKHO is the designated DAC for UK bathymetry data, BODC hosts the General Bathymetric Chart of the Oceans (GEBCO) and is the Global Data Centre for Seabed 2030, which is an initiative to map all of the world's oceans by 2030.

Within the UK, NOC is involved in an initiative with the Maritime and Coastguard Agency (MCA) and industry partners to develop and apply new Marine Autonomous Systems such as Unmanned Surface Vehicles for high-resolution seabed mapping. This forms part of a funding bid under Wave 3 of the Industrial Strategy Challenge Fund, and is being strongly supported by the Department of Transport. Previous attempts to initiate a UK seabed mapping programme have acknowledged the requirement to access the large volumes of seabed data held by industry in areas such as the North Sea.

The above examples all highlight the complexity of the marine data landscape in the UK, and the key role played by NOC in the archiving and dissemination of marine data, including global bathymetry. ***We therefore strongly urge the Geospatial Commission to ensure that NOC is a key partner in this initiative, working closely alongside UKHO (and complementing their domestic focus as a***

Partner Body) by providing access to global bathymetry and UK and global oceanographic data.

Questions

Q1. Is our view of the geospatial data types accurate? If not, what should be included or excluded from this?

Yes, although we suggest that **in the marine environment the impact of temporal change on geospatial data (including bathymetry) should also be considered**. For example, the MCA regularly commission bathymetric "resurveys" in key areas as part of the UK Civil Hydrography Programme in order to measure changes in seafloor bathymetry that may impact navigational safety, e.g. mobile sandbanks, channel infills.

NOC has world-leading expertise in global ocean and coastal modelling, and the measurement of global sea level, hosting the Permanent Service for Mean Sea Level (PSMSL). Changes in global, regional and local sea level will have a major impact on UK shoreline shape and character in the coming decades, influencing geospatial data from this dynamic environment.

NOC will be happy to support the Geospatial Commission through provision of expertise and advice relating to these observed and predicted temporal changes.

Q2. In addition to current government policy, what are the areas of geospatial skills where the commission could best focus, to help ensure the necessary capability within the UK for the future?

NOC encourages the Commission to explore development of **intitiatives and training opportunities for assimilation and interpretation of data across the interface between land and sea**; the coastal zone is of particular strategic importance to the UK and developing geospatial expertise that is able to cross from the marine to terrestrial environment is key to understanding and managing this zone.

Q3. What are the geospatial skills needs and gaps in your organisations, how can these be most effectively addressed, and how can careers in the sector be best promoted?

Not answered.

Q4. Are there any publicly or privately-held geospatial datasets that are currently challenging to access or use or of insufficient quality, but which you or your organisation would find valuable if these issues could be resolved?

Please explain why this would be of value, and how access/quality could be improved?

There are currently large volumes of high-quality seabed and oceanographic data from UK waters that are held by industry (e.g. oil and gas, offshore renewables) that lack regulatory requirement for subsequent public access, even when commercial sensitivity is no longer applicable. Developing mechanisms to unlock and disseminate these industry data through the MEDIN network of DACs would be a good starting point for the Geospatial Commission.

As mentioned in Q1, **improved coastal bathymetry coverage, including quality and repetition of data collection should be a priority.** As well as rocky shores, UK coastlines are made up of mobile sediment that changes with the currents and waves. These sediments form channels, banks and other features that change the coastal bathymetry and morphology over time. Better resolved coastal bathymetry and morphology data sets, would lead to the improvement of modelling for coastal defence and management. Regular and frequent mapping of the changing coast poses a great challenge for data collection and integration, which would require improvement in autonomous technology.

Q5: Do you anticipate that any changes will be needed to both address data and the wider ecosystem, to support emerging technologies? Please provide evidence of value to support any proposed changes.

See Q7 regarding Marine Autonomous Systems.

There is also a need to develop automated systems for effective and efficient data collection and delivery, and the metadata needs to be embeded within the data stream. **There needs to be investment in managing the data from the first point of collection to the end storage and use – from beginning to end**. There is also a need to develop existing systems and geospatial databases so that they are incorporated into wider information systems. Systems need to be flexible and agile and able to respond to developing applications and requirements.

Q6: How should the commission be looking to develop the UK's capability in Earth observation data, both technologically and to support an effective market?

A potential risk that is already impacting NOC is that marine remote sensing is heavily dependent upon recruitment of EU and non-EU scientists to gain the specialism to interpret data - the NOC team comprises mainly international colleagues. Remote sensing is a specialist field that draws on expertise from a small international community.

It is also unfortunate that the dedicated MSc Remote Sensing course at NOC has ended due to a shortage of funding. Our hosting partner, the University of Southampton does, however, incorporate some training but this is only at undergraduate level.

In terms of investment, historically, marine Earth observation has fallen between the National Centre for Earth Observation (NCEO) and the NOC in terms of funding, with the consequence that obtaining funding for basic marine Earth observation (not applications) has been poorly funded.

Q7. Which new technologies should the commission focus on to provide new opportunities to process and exploit geospatial data for economic growth?

NOC is a world-leader in the development and deployment of Marine Autonomous Systems (MAS), having received £30M of UK Government investment in MAS in the current decade, including a £3M Marine Robotics Innovation Centre and the new Oceanids development programme, which forms part of the Industrial Strategy Challenge Fund.

MAS platforms (e.g. Unmanned Surface Vehicles and Autonomous Underwater Vehicles), their onboard sensors (e.g. multibeam bathymetry, biogeochemical) and softwares (e.g. automated command-and-control) provide opportunities to collect high-resolution seabed mapping data at reduced cost (and in some cases higher spatial resolution) compared to manned vessels - MAS will undoubtedly play a significant role in the Seabed 2030 initiative.

The ability for MAS to undertake long-term observations in all weather conditions allows great potential for measuring temporal change. And as well as generating geospatial data, these systems will require geospatial data for safe and efficient operation (see Q18). They are also able to transmit data in real-time via satellite, which is driving new data management tools within BODC to enable through-flow of these data to end users such as UK Met Office and Royal Navy.

Other technologies with varying levels of autonomy include fixed platforms (e.g. shore-based radar and the ARGOS beach camera system), passive drifters and satellites. Integration of these autonomous platform data, with other data sources, would lead to a seamless transition from land to sea when considering problems like flooding, sediment transport and coastal defence, or intertidal fisheries management.

The Commission is strongly encouraged to engage with the NOC to 1) understand

the full potential of MAS to collect and exploit marine geospatial data, 2) identify opportunities for MAS data integration with model and satellite data in order to develop a holistic 4D view of the ocean (see also Q8 below), and 3) explore mechanisms for seamless integration of data collected by autonomous platforms across land and sea.

Q8. How can geospatial data and applications be used to support enhanced roll-out of future technologies?

Integration of satellite and model data with real-time data collected by autonomous and drifting platforms is a key research area for NOC and its partners, and is being applied in new projects in UK waters (e.g. MASSMO – Marine Autonomous Systems in Support of Marine Observations), and overseas as part of the Global Challenges Research Fund and the UK ODA agenda (e.g. SOLSTICE – Sustainable Oceans, Livelihoods and food Security Through Increased Capacity in Ecosystem research, focussed on the Western Indian Ocean). In addition to capturing information about the ocean, data captured can feed back information on how the technology is performing in the field, which in turn can be used to enhance vehicular performance. **Geospatial data layers (and model outpurs) can play a key role in targeting features of interest to the end user**, that are then surveyed in detail with high-resolution *in situ* observations.

Q9: What are the options for how public sector organisations could continue to invest in maintaining and enhancing our geospatial data assets?

A fundamental requirement of centres like the British Oceanographic Data Centre (BODC) is to put data at the heart of research operations.

Some data centres also develop products. The Natural Environment Research Council gave BODC a clear remit to provide open data but not information products, and we believe that this has proved beneficial.

Data centres like the BODC have a role to provide the data and information to underpin the recommendations determined by the Intergovernmental Panel on Climate Change (IPCC).

Contributing data that has societal benefit is a key requirement of public sector organisations. The underlying value of this data is not necessarily reflected in its commercial value.

Q10: What areas of the underpinning geospatial infrastructure such as positioning technologies, including GPS and indoor positioning systems, and geodetic networks and frameworks to support them, should we be prioritising

the development of, in order to support the emerging requirements for geospatial data?

It should be noted that many *in situ* observational platforms, including MAS and Argo floats, rely on the Iridium satellite network for data transfer. Radio and underwater communications are spatially limited and often challenging in the marine environment, so **investing in increased access to satellite networks and reducing cost / increasing resilience would provide a major benefit**.

Q11: What role should the private sector have in both the development and maintenance of the underpinning infrastructure and enhancing the UK's geospatial data assets?

See Q4.

Also, on the instrumentation side, **there is a need to develop and build in standards for marine data that are interoperable**. We would like to be able to work with commercial companies, to be assured that when their sensors start to send us data, that we know what it is. There needs to be knowledge exchange about standards.

Q12. Do you face challenges when working with geospatial data from across the public sector? If so, what are they and how could value be better released? Are there any technical remedies or standards that could be adopted to improve the interoperability of geospatial data? Please provide supporting evidence of what these remedies could help to accomplish.

As mentioned in the Introduction and questions above, the marine data landscape in the UK is complex, and so **ensuring that all existing marine data can be obtained and assimilated will be a key initial challenge for the Geospatial Commission**.

There also needs to be a standard applied to metadata, to ensure all provides and users are speaking the same language. For example, if a data point describes a feature as 'rain' and another data point describes another feature as 'sleet', the technology that needs to read this, must be able to interpret 'sleet' as a sub set of 'rain'.

Vocabularies are used to describe the data - there must be clarity in description and interpretation. There should be standards in both vocabularies and interoperability. BODC is an acknowledged leader in the marine community in terms of developing vocabulary services, and would be happy to support the Geospatial Commission in this aspect.

Q13. How can the Geospatial Commission act as a more effective customer for geospatial data on behalf of the public sector?

As mentioned in the Introduction, although NOC is not one of the initial Partner Bodies of the Commission, our role as the UK centre of excellence for oceangraphic sciences, and as the hosting institution of MEDIN, BODC, and the Seabed 2030 Global Data Centre, **should see us playing a key role in providing marine geospatial data and scientific expertise to the Commission**. We would be happy to discuss this in more detail.

Q14. Are there any additional geospatial datasets, from the other partner bodies or other sources, that the public sector would derive significant benefit from having access to, that might have novel and valuable use cases? What would that access look like?

As per Q4, **it would be beneficial to be able to access commercially-collected bathymetric data** that have been gathered for commercial surveys for use within derived products. e.g. seafloor bathymetry at high resolution. Although we appreciate that this type of data may include commercially sensitive information, if a version could be produced at a lower resolution, e.g. 200 m, this would provide societal benefit in terms of navigation.

Q15: How can we best ensure effective local authority coordination and sharing of best practise, using location data to better deliver public services?

Not answered

Q16: As a result of this analysis, we are prioritising the exploration of possible initiatives in the high-value categories identified:

- **property and land**
- **infrastructure and construction**
- **mobility**
- **natural resources**
- **sales and marketing**

What are the existing or potential geospatial applications which could be scaled-up or developed in order to capture economic value? (We would particularly welcome responses from industry and other bodies engaged in these sectors.)

We recommend that the five themes of Private Sector Use Cases should be expanded to reflect marine, for example:

Property and land – marine data can be used to enhance security of coastal communities in terms of preparation for storm surge and flooding events.

Infrastructure – as mentioned in Q1, marine data can help scientists predict flooding and storm surge events that may compromise infrastructure. In addition, the British Ocean Sediment Core Research Facility (part of NOC) collects data about deep-sea sediments. These data can be used, for example, to provide predictions about the likelihood of submarine landslides, which may lead to tsunamis. Information from deep-sea floor sediments may be used for mapping and surveys, oil and gas exploration, national resource assessment, pollution studies, laying submarine cables and the siting of seafloor structures.

Mobility – data that is derived from monitoring ocean circulation can be used to enable shipping routes to operate with maximum efficiency, saving fuel and time, for example.

All five themes could be enhanced by showing the need for and applications of marine data sets. For example, marine geospatial data can be used to help the UK manage the protection of its coastline and infrastructure (e.g. Thames Barrier), the identification of Marine Protected Areas, and development of sea floor maps to enable society to better manage precious seabed resources. Marine geospatial data underpin environmental impact assessments for marine renewable energy installations and their energy resource assessment.

Q17: Are there any other areas that we should look at as a priority?

NOC again encourages the Commission to ensure that the Strategy reflects the critical role of marine data in delivering societal benefits **both for the UK and the wider global community**.

Q18: What are the main potential private and public sector innovations that will rely on the use of geospatial data to rollout, and are there corresponding regulatory challenges?

The rapidly increasing number of Marine Autonomous Systems in UK seas will require a variety of geospatial data to operate safely and to meet regulatory requirements. In 2016, the UK Marine Industries Alliance (MIA) launched an industry Code of Conduct in respect of surface Maritime Autonomous Systems, however, this is a voluntary code, and new regulations around navigational safety will undoubtedly require real-time access to high-quality geospatial data, e.g. bathymetry.

Hot off the press – linked to the above, in October 2018 it was announced that the

Maritime and Coastguard Agency (MCA) and the Department of Transport (DfT), in collaboration with the NOC, sucessfully secured £1M in a bid to position the UK as a world leader in the autonomous and smart shipping industry. The funding, awarded by the UK Government's Department for Business, Energy and Industrial Strategy's (BEIS) 'Regulators Pioneer Fund', will be used to pioneer new ways of regulating and supporting the autonomous and smart shipping industries to help them deliver innovative new technologies to the traditional maritime sector.

The global autonomous shipping industry is predicted to grow into a $136 billion behemoth by 2030, with UK businesses already playing a key role. The funding will see the creation of a Maritime Autonomy Regulation Lab (physically based at the NOC), where regulators from the MCA and DfT can work with academia and support industry to promote on-water testing and flagship projects and help the UK grow its presence in the global marketplace.

Q19: How best can we make the UK's presence in the international geospatial world more visible?

The Seabed 2030 programme is a high-profile international collaborative project, which will build on the NOC's contribution and commitment to the efforts of the General Bathymetic Chart of the Oceans (GEBCO) - under the auspices of the International Hydrographic Organization and the Intergovernmental Oceanographic Commission - to provide the most authoritative, publicly-available bathymetry data sets for the world's oceans. **It is vital that the Geospatial Commission acknowledges and supports NOC's leading role in the Seabed 2030 initiative**, as it has potential to underpin multiple UK maritime interests, particularly in the Global Britain agenda.

NOC-BODC has been a member of a number of EU initiatives so it is important to maintain our presence within those programmes e.g. the Argo global array of temperature/salinity profiling floats. Some programes have developed into long-term infrastructure in their own right. For example the EU's EMODnet Programme has developed into a leading European endeavour to capture an array of environmental information, including bathymetry, seabed habitats, marine geology, biology, chemistry and physical paramenters along with capturing human activities in the marine encvironment. The sole purpose of the EMODnet Programme is to capture existing data and ensure that they are made available to the public and industry alike.

Another example of a key European programme is the European Multidisciplinary Seafloor and water column Observatory (EMSO). The key contribution of the UK to the EMSO effort has been to collect data from the Porcupine Abyssal Plain sustained ocean observatory, and this has been coordinated by NOC. The EC granted legal status to EMSO, which has been helpful in maintaining the longevity of the programme. If the UK is no longer involved in these programmes, our ability to influence and benefit from these programmes will decrease.

As mentioned in Q12, the UK can enhance its global visibility by building upon its capability in the innovation in vocabularies and interoperability. BODC is an acknowledged leader in the marine community in terms of developing vocabulary services.

Q20: Where should the UK be looking for points of comparison overseas? Who are the other international exemplars? What best practice is being modelled overseas that we can learn from?

We recommend that the UK notes the following points of comparison:

The Australian Marine Data Network

The US' NOAA National Centres For Environmental Information

Germany's Pangea Data Publisher for Earth & Environmental Science

The EU's EMODnet and SeaDataNet

The IOC-UNESCO's IODE

Thank you for your time in completing your response to our call for evidence.

Any questions, please get in touch with the Geospatial Commission via geospatialcommission@cabinetoffice.gov.uk

Geospatial Commission: Call For Evidence Response Questionnaire

Please submit your completed questionnaire to:

geospatialcommission@cabinetoffice.gov.uk.

Clearly title your email *'Call for evidence response'*.

About you and your organisation

Name	[Text redacted]
Organisation	National Physical Laboratory (NPL)
Job title	[Text redacted]
Address	[Text redacted]
E-mail	[Text redacted]
Telephone	[Text redacted]

Please select which of the following best describes you as a respondent:

Respondent	**Please mark with a X**
Academic	
Business representative / trade body	
Central government	
Charity or social enterprise	
Individual	
Legal representative	
Local government	
Large business (over 250 staff)	
Medium business (50 to 250)	
Small business (10 to 49)	
Micro business (up to 9)	

Other - please state	Public Sector Research Organisation

Call for evidence - three key themes

We have identified three high-level themes that could help our approach to setting a strategy which are as follows:

1. **Supporting innovation in the geospatial sector**, exploring how to secure cutting edge skills, the right access to data, and opportunities from emerging technologies for the geospatial sector itself
2. **Enhancing the UK's geospatial assets,** looking at how best to align interests, avoid duplication, and instill best practice across the whole public sector
3. **Driving investment and productivity in geospatial applications**, asking in which wider sectors the most value lies from better exploitation and use of geospatial data, in the UK and internationally

Our questions

Q1. Is our view of the geospatial data types accurate? If not, what should be included or excluded from this?

NPL agrees that the view of geospatial data types within the strategy are accurate. However we believe that temporal data should also be included. **Accurate timestamping of all types of geospatial data will increase traceability of the data, facilitate comparisons across locations, increasing the confidence in the data.** Temporal information should also extend where possible to historical time series to enable climate or other changes to be evaluated.

Q2. In addition to current government policy, what are the areas of geospatial skills where the commission could best focus, to help ensure the necessary capability within the UK for the future?

NPL supports the Government's inclusive approach to improving UK citizens' digital skills, including life-long learning opportunities, as addressed through the digital strategy.[1] It is important that all citizens have the skills needed to access, interpret and make use of digital data and this applies to geospatial data.

To increase the UK's capability in the geospatial sector, the Government needs to continue to invest in embedding mathematical skills at all stages of education and upskilling the workforce. This should include **basic knowledge of uncertainties in all stages of data processing**, with these skills being further developed and extended into all postgraduate geo-spatial skills training. Continual professional development opportunities are needed to support capabilities within the workforce covering uncertainty analysis, quality assurance (QA) and communicating this information. This could significantly enhance the strength of geospatial data and it would ensure that the maximum number of datasets can be meaningfully utilised.

[1] UK Digital Strategy, Department for Digital, Culture, Media and Sport (2017)

Q3. What are the geospatial skills needs and gaps in your organisations, how can these be most effectively addressed, and how can careers in the sector be best promoted?

It should be noted that NPL is largely an added value enabler of geospatial information rather than a user and so our needs are usually met by selected recruitment.

Within NPL we have identified **uncertainty analysis of imagery particularly at per pixel level as a specific skills gap**. We have been addressing this through developing tools and specialist training packages for the community.

The geospatial sector is expanding and new applications and uses of geospatial data are continuing to emerge. For young people starting school today, there will be new opportunities and careers in the sector which may not even exist yet. To ensure that we have a pipeline of skilled people to work in the sector in the future, the Government needs to continue to promote the uptake of Science, Technology, Engineering and Maths (STEM) academic and technical qualifications. There will be a role for the **new technical pathways and science apprenticeships** to help deliver the skills required for the sector.

Q4. Are there any publicly or privately-held geospatial datasets that are currently challenging to access or use or of insufficient quality, but which you or your organisation would find valuable if these issues could be resolved? Please explain why this would be of value, and how access/quality could be improved?

All data starts with measurement and it is essential that **good measurement practice is followed when data is gathered** for these geospatial data sets. This is vital at all stages of the process, and enables scientists to better understand the uncertainty associated with data sets.

In order for publicly accessible or privately held data sets to be utilised effectively and to improve the confidence in the data sets held, the methods of data collection and interpretation processes must be valid and there must be **clear traceability of the data including timestamping**.

Additional metadata must be made available to include information about the **sensors used to gather the data and information about when the instruments were last calibrated and to what standard, which will provide quality assurance (QA)**. We believe that at present it is still quite rare for any dataset (including that of major space agencies) to have all the necessary metadata to provide the QA information on the data set. Enabling this is something that the UK Government could do for the UK geospatial community as a whole and in doing so ensure the national derived information becomes extremely valuable to government and commerce and an exemplar for the world.

Q5: Do you anticipate that any changes will be needed to the both address data and the wider address ecosystem, to support emerging technologies? Please provide evidence of value to support any proposed changes.

NPL believe that the **accurate timestamping of data will improve the comparability and traceability of data generated**. The addition of robust quality metrics on the data sets, and in particular the means to remove biases and enable harmonisation and interoperability, will be fundamental to enable the exploitation through data processing software (i.e. data cubes) and machine learning environments. The provision of analytical tools near to the data sources (avoiding transference of large data volumes) and the incorporation of socio-economic data will open many new applications.

Q6: How should the commission be looking to develop the UK's capability in Earth observation data, both technologically and to support an effective market?

The UK should be working towards **standardising the infrastructure for the provenance of data**. To do this, it is essential that underpinning interoperable ontologies, architecture and analytical tools are developed. Quality assurance is required throughout the data generation process, starting with ensuring that the sensors meet the appropriate standards required, to have confidence in the initial data inputs. It will be important to coordinate the UK's resources to continue to build on networks that are already in place.

New methods for distributed calibration and validation of instruments and methods to remove biases under different environmental and observational conditions before ingestion into data hubs will revolutionise the exploitability of Earth Observation (EO) data. This will facilitate full usage of the new space providers into the mainstream information systems.

The commission should build from the Climate and Environmental Monitoring from Space (CEMS) JASMIN[2] facility **and establish a national database and analytical processing system together with an appropriate QA architecture as a tool for the community**.

[2] http://www.jasmin.ac.uk/what-is-jasmin/ (accessed 18/10/2018)

Q7. Which new technologies should the commission focus on to provide new opportunities to process and exploit geospatial data for economic growth?

The commission should focus on **Artificial Intelligence**, machine learning and the means to enable and establish robust interoperability and the provision of 'fit for purpose' quality metrics.

Q8. How can geospatial data and applications be used to support enhanced roll-out of future technologies?

Geospatial data can be used to **improve ground conditions monitoring from space**, including: changes in ground infrastructure over time, civil infrastructure movement and identifying landslips and flood damage.

It can also be used to inform the **creations of digital twins** for use in city planning, transport systems and Connected and Autonomous Vehicle simulation testing. Other applications include: pollution monitoring, agri-tech applications including the monitoring of crop diseases, planning for forestry management and estimating carbon stores.

Q9: What are the options for how public sector organisations could continue to invest in maintaining and enhancing our geospatial data assets?

Q10: What areas of the underpinning geospatial infrastructure such as positioning technologies, including GPS and indoor positioning systems, and geodetic networks and frameworks to support them, should we be prioritising the development of, in order to support the emerging requirements for geospatial data?

The UK needs to ensure that there are **adequate calibration and validation sites** to provide data to validate satellite observations under a range of conditions.

Q11: What role should the private sector have in both the development and maintenance of the underpinning infrastructure and enhancing the UK's geospatial data assets?

Q12. Do you face challenges when working with geospatial data from across the public sector? If so, what are they and how could value be better released? Are there any technical remedies or standards that could be adopted to improve the interoperability of geospatial data? Please provide supporting evidence of what these remedies could help to accomplish.

NPL is an enabler rather than user of geospatial data. We believe that **interoperability is and will become increasingly an issue**. Our research programmes are looking at how to make interoperable similar datasets such as datasets from Landsat 8[3] and Sentinel 2[4] as well as more complex linkages to Sentinel 3[5] and Sentinel 1[6]. **New standardised methods for scaling, spectrally and spatially are required.**

[3] https://landsat.usgs.gov/landsat-8

[5] https://sentinel.esa.int/web/sentinel/missions/sentinel-3
[6] https://www.esa.int/Our_Activities/Observing_the_Earth/Copernicus/Sentinel-1

Q13. How can the Geospatial Commission act as a more effective customer for geospatial data on behalf of the public sector?

When considering the maximum reuse of data and wide range of potential users the UK should seek to ensure **that high quality information is provided as the default**. Customers such as the Geospatial Commission need to be requesting quality data with uncertainty information as part of the procurement process.

Q14. Are there any additional geospatial datasets, from the other partner bodies or other sources, that the public sector would derive significant benefit

from having access to, that might have novel and valuable use cases? What would that access look like?

Q15: How can we best develop a single UK strategy, ensuring alignment between the individual strategies across the UK while still allwoing for regional variations?

A coordinating body with a vision and regular meetings to build a **common comprehensive architecture for storing and exploiting data** could maximise the value of investments and facilitate maximum growth for the UK economy whilst ensuring all users are well served with comprehensive timely and trustable data.

Q16: How can we best ensure effective local authority coordination and sharing of best practise, using location data to better deliver public services?

Q17: As a result of this analysis, we are prioritising the exploration of possible initiatives in the high-value categories identified:

- **property and land**
- **infrastructure and construction**
- **mobility**
- **natural resources**

- **sales and marketing**

What are the existing or potential geospatial applications which could be scaled-up or developed in order to capture economic value? (We would particularly welcome responses from industry and other bodies engaged in these sectors.)

Q18: Are there any other areas that we should look at as a priority?

We believe that high risk sectors such as **finance, the energy sector** and other areas that are sensitive to climate change should be looked at as a priority.

Q19: What are the main potential private and public sector innovations that will rely on the use of geospatial data to rollout, and are there corresponding regulatory challenges?

The main potential private and public sector innovations that will rely on the use of geospatial data to rollout include **smart integrated transport systems across road, rail, marine and air**. These will increasingly incorporate systems for managing traffic (and therefore lanes/airspace) and the use of automated and eventually autonomous technologies both at the network and at the individual vehicle level. These will rely on a range of data including geospatial which must be trusted and traceable.

Autonomous vehicles will rely heavily on being able to access accurate geospatial data, making decisions based upon understanding their precise location and the location of other vehicles and objects in their vicinity.

Within agriculture there is the potential to use geospatial data to enable **automated farming**, capture data and inform the distribution of land use grants, monitor areas and inform risk mitigation processes and the costing of insurance.

There is the potential to utilise UK innovation platforms and concepts, to support developing nations, using additional data sets to improve the **targeting of aid**, mitigation of disease and monitoring of carbon accountancy sinks and emissions.

Q20: How best can we make the UK's presence in the international geospatial world more visible?

We can make the UK's presence more visible in the international geospatial world through the development of an innovative **data hub and analysis platform with quality assurance (QA) to deliver trusted products**. The ability to have full interoperability and encourage global datasets through UK architecture by providing interoperability/QA metrics alongside the data will place UK at the forefront of innovation. There are many data hubs and analysis platforms in existence or under development, so to make the most of the opportunity the UK has to develop something unique and act quickly to lead in this arena.

Q21: Where should the UK be looking for points of comparison overseas? Who are the other international exemplars? What best practice is being modelled overseas that we can learn from?

Australia has made a major global impact with the export of data cubes and is creating a digital Australia. They are also starting to look seriously at data quality assurance and interoperability as part of this process.

The US and US Geological Survey in particular have good platforms as increasingly do many in the private sector.

Thank you for your time in completing your response to our call for evidence.

Any questions, please get in touch with the Geospatial Commission via geospatialcommission@cabinetoffice.gov.uk

Geospatial Commission:
Call For Evidence Response Questionnaire

Please submit your completed questionnaire to:

geospatialcommission@cabinetoffice.gov.uk.

Clearly title your email *'Call for evidence response'*.

About you and your organisation

Name	[Text redacted]
Organisation	National Records of Scotland
Job title	[Text redacted]
Address	[Text redacted]
E-mail	[Text redacted]
Telephone	[Text redacted]

Please select which of the following best describes you as a respondent:

Respondent	**Please mark with a X**
Academic	
Business representative / trade body	
Central government	**X**
Charity or social enterprise	
Individual	
Legal representative	
Local government	
Large business (over 250 staff)	
Medium business (50 to 250)	
Small business (10 to 49)	
Micro business (up to 9)	
Other - please state	

Call for evidence - three key themes

We have identified three high-level themes that could help our approach to setting a strategy which are as follows:

1. **Supporting innovation in the geospatial sector**, exploring how to secure cutting edge skills, the right access to data, and opportunities from emerging technologies for the geospatial sector itself
2. **Enhancing the UK's geospatial assets,** looking at how best to align interests, avoid duplication, and instill best practice across the whole public sector
3. **Driving investment and productivity in geospatial applications**, asking in which wider sectors the most value lies from better exploitation and use of geospatial data, in the UK and internationally

Our questions

Q1. Is our view of the geospatial data types accurate? If not, what should be included or excluded from this?

Q2. In addition to current government policy, what are the areas of geospatial skills where the commission could best focus, to help ensure the necessary capability within the UK for the future?

Data Scientists are needed as a vital role to work collaboratively with GIS analysts. There is a deficit of trained Data Scientists and as the Geospatial landscape changes they will play a pivotal role in its development. More needs to be done to train and recruit these individuals into the public sector.

Q3. What are the geospatial skills needs and gaps in your organisations, how can these be most effectively addressed, and how can careers in the sector be best promoted?

As above for Data Scientists however a clearly defined career path within central government for both Data Scientists and GIS Analysts would be beneficial as a lot of these highly skilled individuals are forced to move into a middle management post in order to further their career as there is a ceiling to how far they can progress within their specialism.

Q4. Are there any publicly or privately-held geospatial datasets that are currently challenging to access or use or of insufficient quality, but which you or your organisation would find valuable if these issues could be resolved? Please explain why this would be of value, and how access/quality could be improved?

Access

- Getting data: GDPR has added more complexity and restrictions, some of which are totally unnecessary. Most location data, or fixed property type data can be viewed from the street or is available from other sources in some format or another. Demonstrates a lack of confidence / not understanding GDPR by owners of the data.

- Data itself
    - No facility to download from supplier site.
    - No facility to select what data to download, rather than have to take it all
    - Organisational rules prevent direct download even from bonafide sites
    - How to access private sector data
    - Adding value. Restrictions on how other public sector data can be used/can't get it in the first place e.g. access to SEPA flood boundaries to map our Archives. Unable to make our own data free and open because of legacy IPR e.g. NRS digital postcode boundaries,
    - Licensing and IPR
    - Standards
        - No standards exist so difficult to incorporate other datasets
        - those that exist are not fit for purpose e.g. given the widespread use of address BS7666 needs to be reviewed, conflict with RM format resolved
- Quality
    - Links into standards but quality must be maintained. IROAddress data:

- the quality of source data varies between Council Areas, Councils must be adequately resourced to maintain core gazetteers and senior managers /Council Executives made responsible. Address life cycle must be maintained.
- the work to match RM PAF addresses to Council area address by GeoPlace (for OS) contains errors. [Text redacted].
- Aim is a single source of truth.

Q5: Do you anticipate that any changes will be needed to the both address data and the wider address ecosystem, to support emerging technologies? Please provide evidence of value to support any proposed changes.

- Skills and knowledge. IRO Address. Existing addressing products are vast, complicated datasets which require significant skill to manage and interpret in order to extract information on records referring to premises whose identification required for census. General comment,
  - We don't possess the correct skills and knowledge
  - Require senior management to invest / buy in – which is best? A mix?

- Technologies – how do we know what's available to exploit our own data, where do we go for help? Definitely an issue for smaller organisations and ourselves.
  - Our existing website is not conducive to exploiting our data, Geography and other.
  - We don't know what we could do until we know what tools and technologies are available.

- Tools – don't always have correct tools/software to access/manipulate data.
  - Difficulties upgrading software
  - Difficulties obtaining new software
  - Exploit opportunities offered by Open Source

- Costs can be prohibitive e.g. access to OS data though this may change as more data is made open.

- Encourage partnership working across public sector organisations/public private sector ventures – addressing offers opportunities, save money, resource, benefit from external skills, knowledge, technical know-how, contacts etc. Requires change in mind-set and senior management buy in.

- Language – the language used is not necessarily easily understood by senior managers / those who hold the purse strings. Education required to help senior managers understand potential of what could be achieved by unlocking their data.

Given the widespread use and reliance of accurate location for organisations such as Emergency Services, work to roll out Broadband, Scottish Water, ROS and general communication between public sector and the public and accurate definitive address source is critical - a single source of truth. If the current product is not brought up to scratch, organisations will 'do their own thing' which is not in the public interest nor of benefit to the taxpayer – it is inefficient, costly and completely unnecessary. Instead improvements in back office systems and processes leading to greater efficiencies. For that reason we put forward outline proposals for the Commission to look at a Scottish addressing project, it could be in the form of enhancing what exists/collective project for something new e.g. set up an Address Hub. We think there would be significant wider benefits across a variety of government, private, third sector and commercial and infrastructure delivery sectors.

Q6: How should the commission be looking to develop the UK's capability in Earth observation data, both technologically and to support an effective market?

Q7. Which new technologies should the commission focus on to provide new opportunities to process and exploit geospatial data for economic growth?

Q8. How can geospatial data and applications be used to support enhanced roll-out of future technologies?

Q9: What are the options for how public sector organisations could continue to invest in maintaining and enhancing our geospatial data assets?

Q10: What areas of the underpinning geospatial infrastructure such as positioning technologies, including GPS and indoor positioning systems, and geodetic networks and frameworks to support them, should we be prioritising the development of, in order to support the emerging requirements for geospatial data?

Q11: What role should the private sector have in both the development and maintenance of the underpinning infrastructure and enhancing the UK's geospatial data assets?

Q12. Do you face challenges when working with geospatial data from across the public sector? If so, what are they and how could value be better released? Are there any technical remedies or standards that could be adopted to improve the interoperability of geospatial data? Please provide supporting evidence of what these remedies could help to accomplish.

Q13. How can the Geospatial Commission act as a more effective customer for geospatial data on behalf of the public sector?

Q14. Are there any additional geospatial datasets, from the other partner bodies or other sources, that the public sector would derive significant benefit from having access to, that might have novel and valuable use cases? What would that access look like?

- Digitising of archival maps and plans held by the national registers. (Scotland)
- Geotagging of the national archives (Scotland) in order to enable place based searching through thousands of records.

Use Case – New untapped historical geospatial data which has never been made available before. Various potential uses in family histories, land planning, archaeology etc.

Q15: How can we best develop a single UK strategy, ensuring alignment between the individual strategies across the UK while still allwoing for regional variations?

Q16: How can we best ensure effective local authority coordination and sharing of best practise, using location data to better deliver public services?

Q17: As a result of this analysis, we are prioritising the exploration of possible initiatives in the high-value categories identified:

- **property and land**
- **infrastructure and construction**
- **mobility**
- **natural resources**
- **sales and marketing**

What are the existing or potential geospatial applications which could be scaled-up or developed in order to capture economic value? (We would particularly welcome responses from industry and other bodies engaged in these sectors.)

Q18: Are there any other areas that we should look at as a priority?

Historical maps and plans being held in registers and geo-tagging of archival information from registers. (Scotland)

Q19: What are the main potential private and public sector innovations that will rely on the use of geospatial data to rollout, and are there corresponding regulatory challenges?

Q20: How best can we make the UK's presence in the international geospatial world more visible?

Q21: Where should the UK be looking for points of comparison overseas? Who are the other international exemplars? What best practice is being modelled overseas that we can learn from?

Thank you for your time in completing your response to our call for evidence.

Geospatial Commission: Call For Evidence Response Questionnaire

Call for evidence - three key themes

We have identified three high-level themes that could help our approach to setting a strategy which are as follows:

1. **Supporting innovation in the geospatial sector**, exploring how to secure cutting edge skills, the right access to data, and opportunities from emerging technologies for the geospatial sector itself
2. **Enhancing the UK's geospatial assets,** looking at how best to align interests, avoid duplication, and instill best practice across the whole public sector
3. **Driving investment and productivity in geospatial applications**, asking in which wider sectors the most value lies from better exploitation and use of geospatial data, in the UK and internationally

Our questions

Q1. Is our view of the geospatial data types accurate? If not, what should be included or excluded from this?

Collated responses from across the organisation:

- I haven't seen geospatial data types described in this way before but it makes sense and acknowledges that any dataset may have spatial attributes.
- "Geospatial services" is probably the most vague term and from the definition makes it difficult to determine what may and may not be included.
- I believe the data types are well formed.
- In general, the view of geospatial data and data types is too human centric. This is understandable, but hundreds of thousands of species, across all kingdoms, are strongly represented in geospatial datasets.

Q2. In addition to current government policy, what are the areas of geospatial skills where the commission could best focus, to help ensure the necessary capability within the UK for the future?

Collated responses from across the organisation:

- The strategy recognises the need for training to be targeted to different sectors.
- If anything the current approach leads to polarisation and needs to recognise that those working in the environmental sector for example need a suite of skills (geospatial, computing, statistical, environmental and social science…) which are not mutually exclusive.
- School/College/University courses/modules to engage at an early age to ensure core skills are available when entering a workplace. Courses need to embrace more disciplines as well (i.e. not just computer scientists, ecologists, statisticians).
- There are very few industries that would NOT benefit from the use of geospatial skillsets.

Q3. What are the geospatial skills needs and gaps in your organisations, how can these be most effectively addressed, and how can careers in the sector be best promoted?

Collated responses from across the organisation:

- Amongst geospatial professionals there is a tendency to focus on using geospatial data and GIS tools. In providing geospatial services there is a need to better exploit the wide availability of position data sources and to consider the use of a wider suite of tools for combing and analysing geospatial and positional data.
- Understanding how a place 'works' in a dynamic and interdisciplinary sense. It's not enough to be able to locate features and processes in a place; it is essential that we are able to put these together and understand the complex interactions between people and the natural environment in that place; and, crucially, how that place relates to other around it at and across various scales of time and space.
- General lack of understanding, not on what GIS can offer, but the sometimes complex nature of what is requested.
- Due to the great flexibility in GIS software and the products/outputs that are deliverable, some end users, for example, who request a "simple map", don't understand the skill required to deliver that map.

- School/College/University courses/modules to engage at an early age to ensure core skills are available when entering a workplace. Courses need to embrace more disciplines as well (i.e. not just computer scientists, ecologists, statisticians).

Q4. Are there any publicly or privately-held geospatial datasets that are currently challenging to access or use or of insufficient quality, but which you or your organisation would find valuable if these issues could be resolved? Please explain why this would be of value, and how access/quality could be improved?

Collated responses from across the organisation:

- Biodiversity observations datasets (species records) held by a range of organisations should be much easier to access. Much of the data is captured by volunteer surveyors, and then collated and managed by a wide variety of organisations (such as Local Environmental Record Centres, and national recording schemes and societies like Butterfly Conservation, British Trust for Ornithology), who then restrict access to the data. These organisations generate income from licensed data sales or create advantage in securing research funding or reputational benefits from ownership/primacy of publication of data. Public sector investment in many of these organisations ought to deliver publicly-accessible data, however this view is clearly not shared by many of those organisations, and the National Biodiversity Network (NBN) has for many years struggled to resolve this impasse. Declining public sector investment is driving some recording schemes and societies towards greater protection/restriction of data assets at a time when expectations are rising that data created from public investment should be publicly available.

  A national biodiversity data sharing infrastructure now exists (the NBN Atlas, https://nbnatlas.org) , however the intractable problems around access to data mean that this resource is not realising its full potential. Whilst the NBN Atlas currently shares >200 million species records, many of these are not made available openly or at full geospatial precision. Whilst biodiversity data is not openly shared, knowledge of the whereabouts of rare, important, threatened, protected, or otherwise interesting species remains out of reach, reducing the opportunities available to protect them or to enhance the natural environment for all to enjoy. Whilst Natural England may be granted privileged access to some of this data, we increasingly need to work openly with partners/customers who cannot access the same data. A further problem is that many data providers restrict access to ‘non-commercial use’ only, in order to protect income streams – disagreements arise over ‘commercial use’ is defined, creating further obstacles to use.

A current initiative, the Scottish Biodiversity Infrastructure (SBIF) Review, is exploring a new model for a sustainable biological recording infrastructure for Scotland, which may be applicable elsewhere in the UK. The draft proposals would bring about greater access to biodiversity data, but would require significant new funding.

- Detailed soil mapping is currently available under license from Cranfield Soil and AgriFood Institute. Whilst this is licensed to Defra the licensing restricticts the publishing of derived products which means that it is often not used and the licensing costs restricts wider availability.

- In general, the resolution of datasets can be a problem. For example, species observation data may be recorded at 1m resolution or 1000m resolution. Given the increasingly fine resolution of the satellite, LIDAR, drone datasets, we need to improve the resolution of all datasets going forward. Reducing the cost of fine-scale GPS capture equipment would help.

- Furthermore, the greater efforts to standardise datasets may be beneficial, as well as encouraging/improving data validation (e.g. removing free text fields wherever possible, or basic geospatial validation such as checking whether a giraffe is located in the middle of the north sea).

- Data standardisation, stronger metadata definition.

Q5: Do you anticipate that any changes will be needed to the both address data and the wider address ecosystem, to support emerging technologies? Please provide evidence of value to support any proposed changes.

No comments

Q6: How should the commission be looking to develop the UK's capability in Earth observation data, both technologically and to support an effective market?

Collated responses from across the organisation:

- A pan government agreement for access to commercially available imagery.

- As the likes of ESRI and Google are increasingly moving into the EO space we should where possible look to collaborate rather than try to compete, for instance by offering UK Analysis Ready Data made available through their portals.

- Where possible though we should engage with open initiatives. True partnerships between government, commercial and academic institutions is key to exploiting EO through co-development of solutions and shared capability building.

- Beyond the platforms and data processing, the key requirement is sense-making and this requires understanding of underlying processes that give rise to the various patterns and images that EOI generates. While powerful and valuable, statistical modelling is not sufficient as it can offer no explanatory power behind the descriptions it generates. Modelling based on empirical evidence is essential to build and drive process-based models that allow for fully scientific approaches to analysing the data and extracting valuable knowledge. So while an AI/EO engine can spot particular animals in a location; track changes in numbers and spatial distribution over time and generate an idea of the trends and status of that species in that place (and also allow for projections into the future), the engine cannot explain the patterns observed or projected and hence cannot get to the underlying drivers and pressures acting on the system and hence allow us to design and implement effective interventions. So the Commission needs to blend the development of EO/AI capabilities with investments in strengthening underlying scientific capabilities, spanning the natural and social sciences, economics and humanities. Only in this way will we have a fully comprehensive and integrated knowledge system to inform our decisions and advice.

- It is vital that we continue to contribute to EO projects and secure access to future EO datasets. Nature technological progression will inevitably lead to finer resolution datasets that bring about issues not only to do with data processing and the CPU/GPU power required to access that data, but also the recognised storage implications.

- We should continue to strive for greater network speed and improved infrastructure to enable high speed access to these large datasets.

- We also need to find a way to improve the frequency of updates to

represent the rapidly changing landscape due to development, climate change, etc.

Q7. Which new technologies should the commission focus on to provide new opportunities to process and exploit geospatial data for economic growth?

Collated responses from across the organisation:

- The Commission should focus on technologies that enable integration of data collection, curation, processing and sense-making; integrating statistical and scientific approaches and enabling practical, solution-oriented decision-support tools to be developed, shaped by decision-makers themselves in the context of the real-world decisions they have to make.

- EO, machine-learning, and validation (ground-truthing) to establish error margins and better inform decisions.

Q8. How can geospatial data and applications be used to support enhanced roll-out of future technologies?

No comments

Q9: What are the options for how public sector organisations could continue to invest in maintaining and enhancing our geospatial data assets?

Collated responses from across the organisation:

- There are opportunities to improve the quality of datasets through greater partnerships between government and non-government organisations. For example the Ancient Woodland Inventory is being updated through collaboration led by Natural England and the Woodland Trust. National habitat mapping could be updated using a similar approach to Open Street Map.

- Data assets can be enhanced through a clear framework for their integration; so that geospatial data carries explanatory power as well as descriptive power. So geospatial data assets are enhanced through an understanding of their interaction and the processes underpinning those interactions. So rather than a collection of data layers, there is a set of dynamic models underpinning and driving interaction between these layers.

- From a Natural England perspective, we have many data sets from hundreds of projects that are dispersed across many locations. This data would benefit from data validation (geospatial validation and cleaning) as well as greater data standardisation and accessibility.

Q10: What areas of the underpinning geospatial infrastructure such as positioning technologies, including GPS and indoor positioning systems, and geodetic networks and frameworks to support them, should we be prioritising the development of, in order to support the emerging requirements for geospatial data?

Collated responses from across the organisation:

- Access to affordable fine scale GPS would benefit species observations and link to the increasing fine scale EO datasets we have access to.

- Shared/cloud based data storage to reduce duplicated data holdings and for sharing and collaborating with analysis.

Q11: What role should the private sector have in both the development and maintenance of the underpinning infrastructure and enhancing the UK's geospatial data assets?

Collated responses from across the organisation:

- Research and development of new and emerging technologies are where the private sector excel. We are in a position to guide them in terms of the requirements.

Q12. Do you face challenges when working with geospatial data from across the public sector? If so, what are they and how could value be better released? Are there any technical remedies or standards that could be adopted to improve the interoperability of geospatial data? Please provide supporting evidence of what these remedies could help to accomplish.

Collated responses from across the organisation:

- Whilst there has been significant progress in making data open, much of the public sector data holdings remains unpublished and are often difficult to locate. Positional data is a particular problem as it typically held in multitude of databases and data formats which are not interoperable. One challenge is that whilst there are portals for publishing data, such as the NBN Atlas (nbnatlas.org), the structure of the data (such as geospatial relationships) is often not retained.

- Data holdings remaining in non-digital forms with little or no incentive to digitise are major blockers. Easy access to rapid digitisation services is essential to realise the full value of these data.

- If we could standardise our own datasets it would be far easier to provide access to them via a standardised query/search tool. This data would then potentially be open to all via our open-data policy.

- The ability to search geospatial and temporal datasets across the many projects conducted over the years would far improve our ability to establish metrics of change over time, and our ability to correlate those changes to environmental change (climatic, development, etc.).

Q13. How can the Geospatial Commission act as a more effective customer for geospatial data on behalf of the public sector?

No comments

Q14. Are there any additional geospatial datasets, from the other partner bodies or other sources, that the public sector would derive significant benefit from having access to, that might have novel and valuable use cases? What would that access look like?

Collated responses from across the organisation:

- One issue we run into is the lack of open access data that allows a wide variety of uses with little or no constraints. Perhaps we should be encouraging great open-access data across the board?

- Species records datasets collated and held by a variety of non-public-sector organisations (eg Local Environmental Record Centres, or National Recording Schemes and Societies such as Butterfly Conservation, Botanical Society of British Isles, etc) contain millions of observations of species of direct interest to Natural England, Defra, Environment Agency and other public bodies. Access to this data is generally restricted – if more of this data were openly accessible at full detail, we would be able to provide better services – targeting conservation effort, understanding species status and drivers of change, evaluating our inverventions, meeting our reporting obligations, supporting local delivery, and working in partnerhship more effectively because we were able to share the same data without hindrance. Access to such data would be via a portal such as the NBN Atlas. See relevant comments provided under Q4.

Q15: How can we best ensure effective local authority coordination and sharing of best practise, using location data to better deliver public services?

Collated responses from across the organisation:

- Firstly - this requires a greater understanding of HOW public services can be better delivered and then a programme of education/information for local authorities.

- Local authorities are often resistant to change unless there are clear demonstrable benefits and efficiencies that can be achieved. I think this is best demonstrated through full proof of concept projects.

Q16: As a result of this analysis, we are prioritising the exploration of possible initiatives in the high-value categories identified:

- **property and land**
- **infrastructure and construction**
- **mobility**
- **natural resources**
- **sales and marketing**

What are the existing or potential geospatial applications which could be scaled-up or developed in order to capture economic value? (We would particularly welcome responses from industry and other bodies engaged in these sectors.)

Collated responses from across the organisation:

- Natural England's Great Crested Newt licensing project has the potential to be rolled out to other species that require licensing activity. This project benefits both species conservation through the delivery of new habitat for the species (ecologically suitable areas that are geospatially identified at landscape level), but furthermore benefits developers through reduced costs and fewer development delays due to survey restrictions.

Q17: Are there any other areas that we should look at as a priority?

No comments

Q18: What are the main potential private and public sector innovations that will rely on the use of geospatial data to rollout, and are there corresponding regulatory challenges?

No comments

Q19: How best can we make the UK's presence in the international geospatial world more visible?

Collated responses from across the organisation:

- Through the delivery of use-cases developed into peer-reviewed journal articles in high-ranking journals. Where key results from research are also deliverable, these results, along with all new methodologies should be presented at leading international GIS/industry conferences.

Q20: Where should the UK be looking for points of comparison overseas? Who are the other international exemplars? What best practice is being modelled overseas that we can learn from?

No comments

Thank you for your time in completing your response to our call for evidence.

Any questions, please get in touch with the Geospatial Commission via geospatialcommission@cabinetoffice.gov.uk

Geospatial Commission: Call For Evidence Response Questionnaire

Please submit your completed questionnaire to:

geospatialcommission@cabinetoffice.gov.uk.

Clearly title your email *'Call for evidence response'*.

Respondent	**Please mark with a X**
Central government – Environment	**X**

Call for evidence - three key themes

We have identified three high-level themes that could help our approach to setting a strategy which are as follows:

1. **Supporting innovation in the geospatial sector**, exploring how to secure cutting edge skills, the right access to data, and opportunities from emerging technologies for the geospatial sector itself
2. **Enhancing the UK's geospatial assets,** looking at how best to align interests, avoid duplication, and instill best practice across the whole public sector
3. **Driving investment and productivity in geospatial applications**, asking in which wider sectors the most value lies from better exploitation and use of geospatial data, in the UK and internationally

Our questions

Q1. Is our view of the geospatial data types accurate? If not, what should be included or excluded from this?

There is some confusion over how geospatial data differs from positional data, this confusion occurs is with specialists within the industry so may further confuse none specialists or policy makers in the future.

What about other types of data such as big data and temporal data, how will these be considered.

Q2. In addition to current government policy, what are the areas of geospatial skills where the commission could best focus, to help ensure the necessary capability within the UK for the future?

As a national environment organisation, we hold a lot of data, we have some good data analysis skills in house but now need to focus on advanced data management. I believe this is also where the commission needs to focus and promote the skills for the future. These should include

- Data Science
- Machine learning
- Smart algorithms
- BIM

Q3. What are the geospatial skills needs and gaps in your organisations, how can these be most effectively addressed, and how can careers in the sector be best promoted?

We have a good range of Geospatial skills within our organisation any skills gap are around data sciences. These can be addressed by working with other government organisations who have these skills such as GDS and the ONS new data sciences campus based in Newport South Wales.

As organisations we need to focus on analysis and digital professions, GSE and digital data and technology profession. Internally we try to promote professional memberships and charterships through AGI and RGS CGeog.

Careers in the Geospatial sector could be promoted with pay on experience and increased pay for staff with a professional membership and qualification. Some thought needs to be included in how we bridge the public private sector pay gap in the geospatial industry.

Q4. Are there any publicly or privately-held geospatial datasets that are currently challenging to access or use or of insufficient quality, but which you or your organisation would find valuable if these issues could be resolved? Please explain why this would be of value, and how access/quality could be improved?

Before we target what data to go after the commission needs to focus their energy on what data sets will deliver the most results, if we open up OSMM there will be multi benefits for small businesses and we could see a “Geospatial Boom”. However, OSMM is not the be all and end all and another of other datasets or products would deliver better results if open.

Even in a small country such as Wales we don’t share data between organisations in the best way, particularly privately held spatial datasets. While we have a mechanism for sharing open data this is where we stop, a UK wide approach would help us with this.

Q5: Do you anticipate that any changes will be needed to the both address data and the wider address ecosystem, to support emerging technologies? Please provide evidence of value to support any proposed changes.

I think as geospatial colleagues we all agree that location in particularly a physical address is most important.

How do we consider open addressing and in particular emerging technologies such as W3W. In some instances, for us as an organisation operating in remote locations this is more meaningful than a physical address. The stumbling blocks here is that W3W isn’t main stream enough yet. Thought needs to be given to how we can be help and promote future addressing enhancement and projects such as this.

Finally, the UK has a very good comprehensive address gazetteer, however we don’t make enough use of the UPRN. While this is used at a local council level usage could be expanded more to private sector, insurance companies, delivery companies etc. We all know and remember our postcode but hardly anyone knows about the UPRN.

Q6: How should the commission be looking to develop the UK’s capability in Earth observation data, both technologically and to support an effective market?

- Analysis ready data – involvement with Defra projects
- Concerns around a backwards step for earth observation post Brexit
- Lack of super computing resources for data processing
- Earth observations has significant cost savings in terms of field work and monitoring, but we need to re-invest these costs savings in technology improvements and enhancements.

Open sources vs proprietary software in EO, a lot of the support tools are developed by academics in the open source stack, how can we change the perception that open source is a challenge and burden I would like to see a push and lead from example here.

Continued access to the full range of products from the Copernicus programme is a must. In addition, we require access to higher resolution data – this could build on the contracts currently being put in place by the UK Space Agency but with two major changes – the inclusion of current data rather than just an archive, and permission to use the data for operational purposes as well as research projects and proof-of-concepts.

The commission should encourage more EO information sharing between the public, private and third sectors, for example, through funding events and web forums. It would be easier to share data with the third sector if public bodies were allowed to use open source software as a default, which is a win-win situation also minimising cost. Risk-averse ICT departments in public sector bodies may require steer from higher up in government to allow this.

One of the biggest issues with EO is the number of constellations, the way users access them and the different quality levels from each satellite. Could we have a data portal that centralises all EO data (open and proprietary), and options for joining this up with other forms of geospatial data and create a centralised data trading platform. This would be beneficial to query what data is available compare prices, quality, resolution etc. and have tools and infrastructure set up so users can process data to a level they want. An additional benefit can be reducing the number of systems/APIs users have to interact with a create a much smoother and easy to use system. There is potentially a lack of understanding about limitations of different constellations and by bringing them all together this could raise awareness about capabilities of these systems.

Q7. Which new technologies should the commission focus on to provide new opportunities to process and exploit geospatial data for economic growth?

The whole spatial data lifecycle needs to change from capture to publish.

Capture – Investment in 5G to support mobile GIS, but not forgetting rural locations. Some places in Wales don't even have broadband yet alone any form of mobile internet.

Publish – The way each organisation publish data needs to change, some comprehensive organisations have their own open data portals which is great but some don't even have time and resources to publish to data.gov

Consume – The way we consume data neds to change, for the last 5 years at PSMA regional conferences we have reported back on how the PSMA should include data as a service… still waiting.

The use of drone technology is expanding rapidly in the public sector. It would be a great help if the Geospatial Commission facilitated a framework contract of commercial suppliers that public bodies could call off rather than bodies having to do this individually. Again, there is too much focus on economic growth here, to the detriment of other benefits such as resilience to enable rapid response during an environmental incident such as flooding or pollution

Q8. How can geospatial data and applications be used to support enhanced roll-out of future technologies?

Within our internal GIS strategy and 2022 vision for the future we have a number of aspirational future technology enhancements and projects that are reliant on new investments in geospatial data and applications these include.

- Enhanced real time data visualisation
- Augmented reality for species mapping

There are several other Welsh initiatives that will support future technologies such as:

- Wales City Regions
- Wales Valleys taskforce

Q9: What are the options for how public sector organisations could continue to invest in maintaining and enhancing our geospatial data assets?

More emphasis on invest to save projects and collaboration. We talk about key principles like publish once reuse many times and once for Wales, but we don't put these into practice enough.

Ideas such as a national data hub (not just open data) and a National Map office idea. Were all procuring similar or the same data sets several times individually at a huge cost to Government.

We have all data strategies and chief digital officers, the commission need to promote calibration and embark on a joined up journey.

Collaboration e.g. the Defra EO CoE. It is essential to include the Devolved Administrations.

Q10: What areas of the underpinning geospatial infrastructure such as positioning technologies, including GPS and indoor positioning systems, and geodetic networks and frameworks to support them, should we be prioritising the development of, in order to support the emerging requirements for geospatial data?

BIM and Indoor positioning are potential important activities for us an organisation in future. As is remaining part of the EU Galileo program post Brexit.

GPS is everywhere where is great, and locational applications are as popular as ever but how can we take this further such as differential survey grade GPS in our pockets and hand held devices.

Q11: What role should the private sector have in both the development and maintenance of the underpinning infrastructure and enhancing the UK's geospatial data assets?

Work together a lot more in a partnership approach, adopting a shared services model for data where possible. The current method of data sharing and capture is disjointed. For example, as an organisation we design and build a flood scheme, however OS will still go out and capture this instead of making use of our detailed engineering diagrams. Why not support the principle of re using information?

Q12. Do you face challenges when working with geospatial data from across the public sector? If so, what are they and how could value be better released? Are there any technical remedies or standards that could be adopted to

improve the interoperability of geospatial data? Please provide supporting evidence of what these remedies could help to accomplish.

We all operate different applications, standards and procedures therefore all face different challenges when sharing data.

A set of simple data standards would help us when sharing of data. Public sector licencing has got better over the years, but we still have a long way to go. Access to data is a key issue, understanding what data is available and who holds the data, data.gov has gone some way to help with this but this technology should be more customer focused and viewable in a spatial format to allow the use of wms/wfs services.
Lle in Wales needs more promotion, Local Authorities should be encouraged to publish data. The GC should have a role in promoting this and by promoting the advantages for the authority

Q13. How can the Geospatial Commission act as a more effective customer for geospatial data on behalf of the public sector?

The Geospatial commission needs to be the organisation that leads the way for both the public sector and private sector. The commission needs to dictate our strategy for the UK and work more with devolved administrations. The GC should be working with Welsh Government to push for a joined-up approach to ensure access to core data across Wales. Pushing for a Wales SDI that is resourced and managed.

Communicate with all public sector bodies to understand their needs then e.g. act as a bulk buyer for national coverage of high-resolution EO data – see question 6 - this could build on the contracts currently being put in place by the UK Space Agency but with two major changes – the inclusion of current data rather than just an archive, and permission to use the data for operational purposes as well as research projects and proof-of-concepts.

Q14. Are there any additional geospatial datasets, from the other partner bodies or other sources, that the public sector would derive significant benefit from having access to, that might have novel and valuable use cases? What would that access look like?

Were all data rich organisations and should share these across government with any boundaries or restrictions.

Planetscope data at high resolution. Access could be through a portal similar to Defra's Alpha project which includes Analysis Ready Data and high-speed processing in the cloud.
See also questions 6 and 13. Expand the archive of high resolution data currently being purchased by the UKSA to include up-to-date coverage and operational

use.

Q15: How can we best develop a single UK strategy, ensuring alignment between the individual strategies across the UK while still allwoing for regional variations?

Learn from the big 6 but recognise that these are not the only organisations leading the way for geospatial. My own organisation creates more data than some of them.

We need to clearly set out our strategy and vision, but don't reinvent the wheel learn from devolved organisations and other international ventures.

Q16: How can we best ensure effective local authority coordination and sharing of best practise, using location data to better deliver public services?

In wales we work closely with local authority, central government, education and the third sector. AGI Cymru has 12 active members from a variety of backgrounds to help give wales a voice, this is all volunteer time.

As professionals we shouldn't underestimate the involvement of local authorities and their use of data. In my organisation we produce dataset's that are used by 22 local authorities and often get a variety of feedback from them.

Q17: As a result of this analysis, we are prioritising the exploration of possible initiatives in the high-value categories identified:

- **property and land**
- **infrastructure and construction**
- **mobility**
- **natural resources**
- **sales and marketing**

What are the existing or potential geospatial applications which could be scaled-up or developed in order to capture economic value? (We would particularly welcome responses from industry and other bodies engaged in these sectors.)

Natural Resources Wales is the organisation responsible for environment issues in Wales. Our purpose is to ensure that the natural resources of Wales are

sustainably maintained, enhanced and used, now and in the future. As our core remit is around the environment most of our geospatial data fits into the natural resources category. In Wales we need to scale up a national geospatial database, connecting to one Wales wide national database would have huge time and cost savings.

The emphasis on economic value alone here is disappointing and overlooks key sectors such as health and wellbeing. In Wales, all decisions by public bodies must be taken with reference to the Well-being of Future Generations (Wales) Act 2015. The Geospatial Commission need to be aware of this and also take it into account when acting on behalf of the whole UK.
For the individual, if they do not have their health then none of those bullet points matter. The Geospatial Commission must take into account that the governments of other Devolved Administrations have priorities other than money.

Q18: Are there any other areas that we should look at as a priority?

Health and further education are often the forgotten sectors in the geospatial Industry.

Q19: What are the main potential private and public sector innovations that will rely on the use of geospatial data to rollout, and are there corresponding regulatory challenges?

There are a number of current UK big infrastructure projects such as HS2, Heathrow third runway that will utilise huge amounts of spatial data and geospatial technology. These projects should be embracing and promoting spatial e.g. a third run way open data portal, bringing together all of the spatial data sets. As a country we underutilise a chance to promote spatial data in situations such as this.

Real-time monitoring. Privacy and security issues.

Q20: How best can we make the UK's presence in the international geospatial world more visible?

I think the UK has a presence in the wider international geospatial market however I think this is limited solely with a data and data capture focus e.g. OS international. Our presence in the international geospatial world needs to focus on more than just data capture, particularly analysis and the use & impact that spatial data has on problem solving.

Fund specialist public sector employees to attend high profile international conferences e.g. hosted by overseas Space Agencies or organisations such as the European Geosciences Union (whose annual conference now has over 15,000 attendees).

Q21: Where should the UK be looking for points of comparison overseas? Who are the other international exemplars? What best practice is being modelled overseas that we can learn from?

As part of the GIS & Spatial strategy in Natural Resources Wales we have conducted a literature review of other similar geospatial strategies and documents. Australia, New Zealand and Canada all had excellent geospatial strategies which our organisation has learnt from.

European Space Agency – openness of governance, data and software, speed of delivery, culture of collaboration.

Thank you for your time in completing your response to our call for evidence.

Call for evidence - three key themes

We have identified three high-level themes that could help our approach to setting a strategy which are as follows:

1. **Supporting innovation in the geospatial sector**, exploring how to secure cutting edge skills, the right access to data, and opportunities from emerging technologies for the geospatial sector itself
2. **Enhancing the UK's geospatial assets,** looking at how best to align interests, avoid duplication, and instill best practice across the whole public sector
3. **Driving investment and productivity in geospatial applications**, asking in which wider sectors the most value lies from better exploitation and use of geospatial data, in the UK and internationally

Our questions

Q1. Is our view of the geospatial data types accurate? If not, what should be included or excluded from this?

I believe that the four proposed data types are sufficient.

Q2. In addition to current government policy, what are the areas of geospatial skills where the commission could best focus, to help ensure the necessary capability within the UK for the future?

More emphasis should be placed on providing skills around improving the underlying data quality rather than the exploitation of 'art of the possible' and the aspirations/desire of delivering BIM compliant projects. BIM technologies are impossible without high quality interoperable data (with full meta-data) underpinning the foundations.

We should focus skills on the longevity and interoperability of datasets. Encouraging industries to developing geospatial data that could have benefits across other disciplines would reduce the silo-mentality that currently exists.

Q3. What are the geospatial skills needs and gaps in your organisations, how can these be most effectively addressed, and how can careers in the sector be best promoted?

There is a big division of geospatial knowledge between geospatial practitioners and more senior figures who are being influenced by external industry. In large organisations there often tends to be very little internal review of their own capabilities from senior figures before initiating 'revolutionary programmes'. Geospatial practitioners spend too long managing expectations of high-level geospatial concepts whilst they are firefighting the basic data quality and data improvement issues.

There are pockets of excellence in some areas of the business but we lack the overarching backing of the company to actively recognise cross-organisational geospatial issues as fundamental to what we do.

The Cabinet Office could actively encourage cross organisation collaboration for the benefit of all involved.

Q4. Are there any publicly or privately-held geospatial datasets that are currently challenging to access or use or of insufficient quality, but which you or your organisation would find valuable if these issues could be resolved? Please explain why this would be of value, and how access/quality could be improved?

Our organisation spends far too long concerned with the politics and licencing of data than we do with data quality and exploitation of the data.

For example, Network Rail has been denied PSMA twice from the Ordnance Survey. This has significant costs to our business, our innovation, data sharing across our supply chain and our delivery of works.

We often end up using the lower quality open source data in favour of the preferred OS MasterMap data / OS Water Networks, OS Highways etc. This is reflected across many industries. Opening up the best available data to all businesses will inspire innovation from all industries. Network Rail would be

available to provide enhanced, more accurate decision based solutions if they had access to particular data sets.

This has a knock on effect to the accuracy and applicability of our own analysis. We have considerable contracts in place with other organisations who also act on behalf of government departments. The administration and management of these contracts alone divert a significant amount of geospatial resources that could otherwise be employed on more data enhancements and exploitation.

Q5: Do you anticipate that any changes will be needed to the both address data and the wider address ecosystem, to support emerging technologies? Please provide evidence of value to support any proposed changes.

Addressing is a fundamental part of how our country operates. The omission of Royal Mail from the commission is a concern.

Likewise the omission of the Meteorological Office is a concern. Weather and climate data should be open to all to use and interpret.

With emerging technologies enabling a more personalised mobile society, will future address data need to adjust likewise?

Network Rail has the requirement to address several assets that would not normally receive a standard address point. Bridges, access points, and locations that do not necessarily have direct road access require hierarchical geospatial positional information similar to the way that postcodes currently work. Addressing needs to move beyond building delivery points to introduce an interoperable cross-organisation standard.

Q6: How should the commission be looking to develop the UK's capability in Earth observation data, both technologically and to support an effective market?

Earth Observation is one of many data sources. Like many datasets, it has benefits and disadvantages and is suitable for a select number of applications.

One of the biggest advances in a wirelessly connected world for Network Rail is the potential of near real-time monitoring. Installation of ground based Remote Condition Monitoring stations across our highest risk assets have enabled the business to receive near real-time data on the condition of assets. This only provides feedback on monitored assets. Earth observation technology offers the potential of remote monitoring without the need for fixed infrastructure that would otherwise need its own maintenance.

Earth observation will never replace constant monitoring of assets as it is not real-time but does provide the opportunity to receive periodic snapshots of asset conditions. This would enable retrospective monitoring of asset degradation or land use change.

Currently Sentinel based earth observation technologies don't provide nationwide coverage due to the angle of sensors and the orbit. Also the resolution varies across the country. This prevents a national organisation from fully adopting such a data source. National consistency is one of the biggest benefits of Ordnance Survey data.

Acquisition for earth observation data is on a large tiled basis only. Therefore linear infrastructure owners would have to acquire / process large data sets containing unnecessary information rather than a specific area of interest.

As with all raster based datasets, EO data is large and requires significant resources for storage. The geospatial commission could investigate the potential of centrally hosting such services across multiple businesses.

Q7. Which new technologies should the commission focus on to provide new opportunities to process and exploit geospatial data for economic growth?

Organisations should not be forced to adopt one particular format as this could be very restrictive. The Commission should focus on the development of (meta) data standards and data integration. The commission should be seen as the enabler to reform the interoperability of data between organisations by enforcing minimum standards.
Perhaps the enforcement of open source data standards would enable software vendors to better integrate and share data across organisations.

Q8. How can geospatial data and applications be used to support enhanced roll-out of future technologies?

Consistency of geospatial referencing and addressing across organisations through enforced meta-data standards.

Possible mobile address system that enables personalised delivery of information / physical objects based on the individuals location.

The integration of open transportation and travel time information would ensure all delivery services could provide more accurately predicted delivery windows for products and services.

The integration of geospatial data from multiple organisations could open up

possibilities of infrastructure sharing. For example utilising the railway corridor for additional services / cabling / UAV delivery routes etc.

Q9: What are the options for how public sector organisations could continue to invest in maintaining and enhancing our geospatial data assets?

By opening up geospatial data, organisations would lose potential revenue from selling to other businesses. This loss of revenue would need to be quantified and compensated for in order to encourage the openness of data sharing.

Public sector investment should also consider improvements to data quality, maintenance and assurance to continue to deliver to meet the needs of the end users.

There is a potential option for connecting public with private sector organisations in order to develop a more sustainable investment model for geospatial strategies, rather than considering them as separate entities.

Q10: What areas of the underpinning geospatial infrastructure such as positioning technologies, including GPS and indoor positioning systems, and geodetic networks and frameworks to support them, should we be prioritising the development of, in order to support the emerging requirements for geospatial data?

Increasing nationwide coverage of technologies upon which geospatial data relies. Technology becomes very limited from a national organisation perspective when you can only access it in densely populated locations.

Q11: What role should the private sector have in both the development and maintenance of the underpinning infrastructure and enhancing the UK's geospatial data assets?

Without mandating any data sharing / delivery to public organisations etc there is no incentive for private companies to open up their data.
Private organisations need to be incentivised to deliver collaborative projects that minimise impact on end users. For example, utility companies should share access arrangements to buried services rather than repeatedly digging up the same piece of road inconveniencing the general public.

Q12. Do you face challenges when working with geospatial data from across the public sector? If so, what are they and how could value be better released? Are there any technical remedies or standards that could be adopted to improve the interoperability of geospatial data? Please provide supporting evidence of what these remedies could help to accomplish.

Data alignment and interoperability are probably the biggest issue. There is such a variety in data quality with little or no meta data. The mandating of data standards would alleviate some of the frustrations associated with cross-organisation data sharing.

Q13. How can the Geospatial Commission act as a more effective customer for geospatial data on behalf of the public sector?

Enforcing a mandate of geospatial data quality / sharing agreements / meta data standards and interoperability standards.

Q14. Are there any additional geospatial datasets, from the other partner bodies or other sources, that the public sector would derive significant benefit from having access to, that might have novel and valuable use cases? What would that access look like?

I believe that the proposed 6 partner bodies limit what the commission could achieve. By broadening the scope of partner bodies it would be possible to engage with a wider audience and enable the Geospatial Commission to gain influence across a more diverse range of industries.
Other industries that should be involved include:
Transportation:

1) Highways England (and their equivalents across the UK)
2) Network Rail
3) Regional rail / tram / light rail providers
4) Local Authorities roads

Addressing:

1) Royal Mail
2) Local Authorities

Aviation

1) CAA – in a world of increasing UAV use
2) NATS

Meteorological

1) Met Office – with increasing issues relating to climate change it is important to share this data with other partner bodies

Earth Observation

1) Sentinel data – Whilst this data is available to use, it's current delivery mechanisms prevent it from being more widely adopted.

Environmental

1) Environment Agency (and their equivalents across the UK) – ensuring consistency across borders.

Whilst Opendata.gov.uk provides access to a lot of geospatial content, this needs to be enhanced. The user interface for interaction with data should be geospatial. Enabling users to query data on the fly online would prevent the need for business to constantly download data.
The tracking of data concurrency is difficult and users should be able to receive notifications of when a data set they have downloaded or 'follow' is updated.

Q15: How can we best develop a single UK strategy, ensuring alignment between the individual strategies across the UK while still allwoing for regional variations?

Devolution across many industries has benefits and pitfalls. Ensuring geospatial consistency and compliance with standards across multiple devolved organisations is very difficult unless it is mandated from the government.
Future geospatial innovations will have limitations without consistent approaches across the entire country.
Unless the geospatial commission looks to promote and mandate standards then it will be very difficult for the UK to become a leader in geospatial strategies and innovations.

Q16: How can we best ensure effective local authority coordination and sharing of best practise, using location data to better deliver public services?

Mandating a national standard of data quality & meta data along with the necessary investment in high quality data capture to ensure the concurrency and accuracy of data.
Incentivise with financial reward for compliance and financial penalties for non-complince.

Q17: As a result of this analysis, we are prioritising the exploration of possible initiatives in the high-value categories identified:

- **property and land**
- **infrastructure and construction**
- **mobility**
- **natural resources**
- **sales and marketing**

What are the existing or potential geospatial applications which could be scaled-up or developed in order to capture economic value? (We would particularly welcome responses from industry and other bodies engaged in these sectors.)

OpenStreetMap offers subscribed members the opportunity to contribute to the base map to enhance the overall offering. By enabling crowd-sourced rule-based editing for certain Ordnance Survey products could enhance the data offering, especially in more rural areas where there are less frequent updates to Ordnance Survey products.
Ensuring that any data captured by local authorities or utilities organisations complies with and synchronises with Ordnance Survey MasterMap data.

Q18: Are there any other areas that we should look at as a priority?

Q19: What are the main potential private and public sector innovations that will rely on the use of geospatial data to rollout, and are there corresponding regulatory challenges?

The extended use of UAVs would certainly benefit from enhanced geospatial accuracy.

Q20: How best can we make the UK's presence in the international geospatial world more visible?

In order to enhance our visibility we need to be seen to be more open and more collaborative than we currently are. Ultimately tax payers are funding data sharing across government organisations multiple times despite already paying for the data capture. This is seen as a massive waste of government resources.
The UK can't become an international standard of excellence in this area without first breaking down the barriers that prevent innovation and collaborative working within its own government.
Lead by example.

Q21: Where should the UK be looking for points of comparison overseas? Who are the other international exemplars? What best practice is being modelled overseas that we can learn from?

Integrated public transport services are made possible by understanding where and when services interchange. Many European countries provide significating

Opening up visibility of services could increase economic value. For example live train tracking software enables smoother transitions between public transport. See this example of live Swiss trains.

www.Maps.vasile.ch/transit-sbb/

Thank you for your time in completing your response to our call for evidence.

Any questions, please get in touch with the Geospatial Commission via geospatialcommission@cabinetoffice.gov.uk

Geospatial Commission: Call For Evidence Response Questionnaire

Please submit your completed questionnaire to:

geospatialcommission@cabinetoffice.gov.uk.

Clearly title your email *'Call for evidence response'*.

About you and your organisation

Name	[Text redacted]
Organisation	Network Rail (Asset Information Services)
Job title	[Text redacted]
Address	[Text redacted]
E-mail	[Text redacted]
Telephone	[Text redacted]

Please select which of the following best describes you as a respondent:

Respondent	**Please mark with a X**
Academic	
Business representative / trade body	
Central government	
Charity or social enterprise	
Individual	
Legal representative	
Local government	
Large business (over 250 staff)	**X**
Medium business (50 to 250)	
Small business (10 to 49)	
Micro business (up to 9)	

Other - please state	

Call for evidence - three key themes

We have identified three high-level themes that could help our approach to setting a strategy which are as follows:

1. **Supporting innovation in the geospatial sector**, exploring how to secure cutting edge skills, the right access to data, and opportunities from emerging technologies for the geospatial sector itself
2. **Enhancing the UK's geospatial assets,** looking at how best to align interests, avoid duplication, and instill best practice across the whole public sector
3. **Driving investment and productivity in geospatial applications**, asking in which wider sectors the most value lies from better exploitation and use of geospatial data, in the UK and internationally

Our questions

Q1. Is our view of the geospatial data types accurate? If not, what should be included or excluded from this?

Yes they are

Q2. In addition to current government policy, what are the areas of geospatial skills where the commission could best focus, to help ensure the necessary capability within the UK for the future?

- Working cross industry iniatives
- High quality interoperable data with full meta-data to common standards so that users of data can assess what a given data set can be used for
- To improve the interoperability of legacy data/information
- Legal issues, e.g. liability for any data reported about 3rd party assets
- Security issues, e.g. security concerns over critical infrastructure
- Potential impact on revenue for data suppliers, e.g. lost revenue from services
- Historically no incentive to move beyond the bare minimum re information supply
- No clear mandate from govt. to share information
- Differing levels of technological advancement re provision of electronic data; cost of technology improvement a potential barrier and could be perceived to outweigh any benefits from sharing information
- Commercial sensitivity issues
- Lack of central repository for companies to securely store/update their datasets

Q3. What are the geospatial skills needs and gaps in your organisations, how can these be most effectively addressed, and how can careers in the sector be best promoted?

- Aerial survey/drone capture and LIDAR
- Augmented Reality
- FME analysis
- CAD skills
- Need more focus on data quality and data improvement
- Administration/Management of contracts use a significant amount of geospatial resources
- Basic compentancy in understanding geospatial data for front line staff

Q4. Are there any publicly or privately-held geospatial datasets that are currently challenging to access or use or of insufficient quality, but which you or your organisation would find valuable if these issues could be resolved? Please explain why this would be of value, and how access/quality could be improved?

- Though being declared as a wholly publicly owned entity Network Rail (NR) has consistently been refused entry to the Public-Sector Mapping Agreement (PSMA) on commercial technicalities. This has limited NR to an "Area of Interest" (AOI), restricting the amount of data available to the business. When extra data is required beyond the AOI, it has been at an additional cost both in terms of the extra geographic coverage required and the specific OS Mastermap (OSMM) derivatives needed. Though OS' negotiating position has softened and informal membership has been tabled it would still require NR to maintain its substantial financial contribution, the resources could readily be redeployed to drive innovation regarding the use of Geospatial data within the management of the GB rail infrastructure.
- In general licensing of data is challenging/ time consuming/ (including NDA's)
- After meeting with one of the Geosptial Commission reps – my understanding is that both the Royal Mail and the Met Office are not included in this commission – this is concening as this is type of data should be available

Q5: Do you anticipate that any changes will be needed to the both address data and the wider address ecosystem, to support emerging technologies? Please provide evidence of value to support any proposed changes.

- Investigate emerging technologies such as What3Words to integrate and make interoperable with existing gazetteers.This would allow the UK to utllise other address technologies and software which would not be constrained by the limitations and complexity of GB addressing (NLPG/AddressBase/PAF). This would broaden choice and strengthen the commercial procurement of the UK public sector.
- Network Rail has the requirement to address assets that would not normally receive a standard address point. For example bridges, access points, and locations that do not necessarily have direct road access require hierarchical geospatial positional information similar to the way that postcodes currently work.

Q6: How should the commission be looking to develop the UK's capability in Earth observation data, both technologically and to support an effective market?

- Earth observation data is on a large tiled basis only. Therefore linear infrastructure owners would have to acquire / process large data sets containing unnecessary information rather than a specific area of interest.

- As with all raster based datasets, EO data is large and requires significant resources for storage. The geospatial commission could investigate the potential of centrally hosting such services across multiple businesses.

Q7. Which new technologies should the commission focus on to provide new opportunities to process and exploit geospatial data for economic growth?

- Open source data standards
- Commission should focus on the development of (meta) data standards and data integration.
- Industry and Asset specific feature extraction tools to collect and validate national infrastructure data sets

Q8. How can geospatial data and applications be used to support enhanced roll-out of future technologies?

- Augmented Reality eg BIM for stations, tunnels etc
- Geosptial/Location data has to be at the heart of an integrated and automated transport infrastructure system, this applies to multi model transport – specifically automated train operations (ATO) systems and driverless vehicles, both personel and commercial

Q9: What are the options for how public sector organisations could continue to invest in maintaining and enhancing our geospatial data assets?

- Increased collaboration between public sector organisations which would include the rationalisation of databases
- Loss of revenue (from selling data) would impact companies willness to participate in data sharing – this would need to be quantified and compensated
- Need to create a new economy which quantifies the value of the exploitation of data and shift the focus away from recovering the cost of data collection and treating data sets themselves as commercial assets.
- A national central repository for all authorities and utility companies to share their information in a geospatial format (underground assets specific)

Q10: What areas of the underpinning geospatial infrastructure such as positioning technologies, including GPS and indoor positioning systems, and geodetic networks and frameworks to support them, should we be prioritising the development of, in order to support the emerging requirements for geospatial data?

- Importance of 3G/4G/5G coverage to be very high so that reliability of using GPS.
- Also increased number of satellites if cost permits. Regardless of Brexit outcome the UK's ongoing participation in the Galleo Project or an equivalent must be secured.
- For Network Rail - Certainly a need for all locations to be captured with high resolution eastings and northings rather than ELRs and mileages.

Q11: What role should the private sector have in both the development and maintenance of the underpinning infrastructure and enhancing the UK's geospatial data assets?

- Increased competition between private firms will arguably raise the standards in data quality, if they are going to secure contracts etc - so there is a role for private organisations. (concepts such as BIM)

- Without mandating any data sharing / delivery to public organisations etc there is no incentive for private companies to open up their data.

- This is particularly showcased in the example of Utilities Companies – there are pockets of best practice here and collaboration, however many will not participate in Data Sharing initiatives. The Vault initiative in Scotland is an example of best practice.

.

Q12. Do you face challenges when working with geospatial data from across the public sector? If so, what are they and how could value be better released? Are there any technical remedies or standards that could be adopted to improve the interoperability of geospatial data? Please provide supporting evidence of what these remedies could help to accomplish.

- Data alignment and interoperability
- Data currency and accuracy issues.
- Also knowing who to contact regarding datasets and which are the most up to date.
- Example : every local government has a different approach and standards, which could be standardised. Devolution should still require consistent standards.
- The commercial constraints placed upon the use of OSMM and other premium mapping data products by OS requires NR to maintain several staff to oversee sub-contractor licences as well as data sharing licenses with our vast supply chain and the wider railway industry which consists of both private and public-sector organisations. The administration of this is time consuming and often exhausting as organisations challenge the terms of boiler plate licenses, legal agreements, and caveats regarding data reuse.

Q13. How can the Geospatial Commission act as a more effective customer for geospatial data on behalf of the public sector?

- Enforcing a mandate of geospatial data quality / sharing agreements / meta data standards and interoperability standards.
- Some of NR's key datasets contain legacy OS IPR embedded within them, this has stifled NR's ability to produce truly open datasets. This in turn has frustrated the wider railway industry, academia, and contributors as they must sign up to legal agreements and sub-contractor licences limiting any commercial data reuse and therefore negating any benefit that might be gained through data driven innovation/R&D. NR has recognised this and has invested a significant amount in survey and data cleansing activity that will ultimately lead to the ability to produce these datasets in a truly open manner after removing any legacy OS IPR.

Q14. Are there any additional geospatial datasets, from the other partner bodies or other sources, that the public sector would derive significant benefit from having access to, that might have novel and valuable use cases? What would that access look like?

- Met Office
- Environment Agency
- British Geological Survey
- Highways England,
- Utility companies such as telecoms, water, gas and electricity.
- Network Rail and other regional rail / tram / light rail providers
- Local Authorities
- Royal Mail
- CAA
- Local authorities

Q15: How can we best develop a single UK strategy, ensuring alignment between the individual strategies across the UK while still allwoing for regional variations?

- Ensuring compliance with standards is very difficult unless it is mandated from the government.
- More support for legislation that guarantees' open data within the public sector and cross industry

- Unless the geospatial commission looks to promote and mandate standards then it will be very difficult for the UK to become a leader in geospatial strategies and innovations.

Q16: How can we best ensure effective local authority coordination and sharing of best practise, using location data to better deliver public services?

- Regular stakeholder groups to ensure consistent standards across local authorities.
- Incentivise for compliance and financial penalties for non-compliance.

Q17: As a result of this analysis, we are prioritising the exploration of possible initiatives in the high-value categories identified:

- **property and land**
- **infrastructure and construction**
- **mobility**
- **natural resources**
- **sales and marketing**

What are the existing or potential geospatial applications which could be scaled-up or developed in order to capture economic value? (We would particularly welcome responses from industry and other bodies engaged in these sectors.)

- OpenStreetMap offers users the opportunity to contribute to the base map to enhance the overall offering. However if OS data was fully open and free to use, OpenStreetMap would not be required?
- Crowd-sourced rule-based editing for certain Ordnance Survey products could enhance the data offering, especially in more rural areas where there are less frequent updates to Ordnance Survey products.
- Ensuring that any data captured by local authorities or utilities

organisations complies with and synchronises with Ordnance Survey MasterMap data. (MetaData standards/ Inspire)

Q18: Are there any other areas that we should look at as a priority?

- Environmental eg weather, geology, soils, flooding, rivers, coastal erosion etc

Q19: What are the main potential private and public sector innovations that will rely on the use of geospatial data to rollout, and are there corresponding regulatory challenges?

- For Network Rail , an example here would be the Digital Railway - this will be dependent on GPS etc for ETCS and real-time positioning systems. ATO as referred to earlier in the questionnaire

Q20: How best can we make the UK's presence in the international geospatial world more visible?

- Increase collaboration and engagement, and be involved with cross industry projects to increase the UK's reputation.
- Geospatial Consultancy should be added to all UK trade showcases

Q21: Where should the UK be looking for points of comparison overseas? Who are the other international exemplars? What best practice is being modelled overseas that we can learn from?

- This question identifies the value of sharing best practice on the international stage with stakeholders involved in similar work.

Thank you for your time in completing your response to our call for evidence.

Call for evidence - three key themes

We have identified three high-level themes that could help our approach to setting a strategy which are as follows:

1. **Supporting innovation in the geospatial sector**, exploring how to secure cutting edge skills, the right access to data, and opportunities from emerging technologies for the geospatial sector itself
2. **Enhancing the UK's geospatial assets,** looking at how best to align interests, avoid duplication, and instill best practice across the whole public sector
3. **Driving investment and productivity in geospatial applications**, asking in which wider sectors the most value lies from better exploitation and use of geospatial data, in the UK and internationally

Our questions

Q1. Is our view of the geospatial data types accurate? If not, what should be included or excluded from this?

Yes, seems reasonable

Q2. In addition to current government policy, what are the areas of geospatial skills where the commission could best focus, to help ensure the necessary capability within the UK for the future?

Short technical courses are extremely expensive. University and college course are often too broad and not focused on particularly outcomes. Some subsided funding for these would go some way to filling that skills gap.

Q3. What are the geospatial skills needs and gaps in your organisations, how can these be most effectively addressed, and how can careers in the sector be best promoted?

With eight years of austerity most of the GIS resources within our Authority have been lost. So, skills and resources wise we are probably worse now than we have ever been. We have made five GIS Officers redundant and hundreds of GIS users have left over that period. These are not going to be replaced any time soon. In association with lack of skills we have seen a huge reduction in in GIS projects and a degradation in the availability and quality of spatial datasets across the authority. Data that we have are often locked away and won't be shared because of fears over quality.

There is very limited budget for GIS training.

There is a pressing need to fund or subsidise training and provide technical courses in 'development / coding' (e.g. python) for GIS Officers / IT developers to bridge the gap between GIS and traditional IT development activities.

Outcomes – increase in availability and quality of spatial datasets (such as those that could be published as 'open data'). Provision of geospatial applications within the authority for internal/external use that would improve channel shift and the increased efficiencies around data management and processing (e.g. through spatial database warehousing).

Q4. Are there any publicly or privately-held geospatial datasets that are currently challenging to access or use or of insufficient quality, but which you or your organisation would find valuable if these issues could be resolved? Please explain why this would be of value, and how access/quality could be improved?

Access to Land Ownership causes the most problems and having a current, complete digital land ownership layer would be most beneficial internally. We have a mixed inventory consisting of paper maps (the standard) and a partially complete digitised version which cost over £100k. There is no further funding to capture and QA the rest.

We regularly carry out repairs and services on land we do not own. Because other key data such as Adopted Highway, and Grounds Maintenance are not updated (and not shared because of inferior quality) and the difficulty accessing ownership details makes what should be a simple query a protracted affair. However, in many cases this would breach SLA's service delivery times and therefore requests are completed without ascertaining if it's our responsibility.

Q5: Do you anticipate that any changes will be needed to the both address data and the wider address ecosystem, to support emerging technologies? Please provide evidence of value to support any proposed changes.

The Gazetteer custodian should be made into a statutory role like SNN otherwise it's just not resourced correctly. Our team has continued to shrink - We have lost 4 Gazetteer Officers through redundancies, yet the Data Cooperation Standards increase annually. This affects data quality – we were Below Standard for 10 months in 2017 and are currently still below standard in 2018.

There should only be one master address dataset – need to merge PAF and Address Base (Gazetteer).

The 'full' Address should be open data – small business cannot afford to license addressing data.

This would provide more value and lend itself to an easier maintenance process for all concerned. I believe making Addressing open would be more beneficial than opening up MasterMap *per se*.

Q6: How should the commission be looking to develop the UK's capability in Earth observation data, both technologically and to support an effective market?

We make use of high resolution LIDAR data and this has helped to land successful bids in projects (e.g. identification of properties suitable for solar pv):

http://www.iscopeproject.net/

However, any data such as this which is current, complete and good quality is expensive to update. It would be useful if this could be incorporated into the APGB. The current offerings are adequate for basic land type applications but not really good enough for advanced analysis (e.g. 0.5m resolution and banded lidar (point clouds) in asl format). LIDAR, CIR and other remotely sensed products are often not that user friendly when rasterised and need vectorizing into something that becomes more useful for most GI users.

Procesing raster's requires specialist tools and these are expensive. Developing an open source raster API's, GIS toolset or improving existing tools (GRASS) and improving the open source libraries (e.g. GDAL) will help unlock potential in this area.

Q7. Which new technologies should the commission focus on to provide new opportunities to process and exploit geospatial data for economic growth?

One of the biggest issues in the Geospatial sector is the prohibitive cost of licensing. This makes growth and tech start-ups very difficult. It makes it hard to develop the business case based on R & D that requires some very expensive licensing to get started! It's not 'new' but the use of open source technology that can be shared has to be assessed. Many proprietary products use open source code beneath the bonnet (think FME, ArcGIS).

We have successfully run a mixed estate making use of GeoServer, PostGIS and QGIS desktop for the last five years. We have cut the ESRI product set to a minimum to reduce costs.

There needs to be some work done on the business models to help those companies to become sustainable. That said there a few companies around that provide implementation, support and development in open source GIS.

Q8. How can geospatial data and applications be used to support enhanced roll-out of future technologies?

It's the pyramid affect – we need to get the foundations in place with good quality core datasets, open source tools, open standards and the right skills. Once the foundations are built the higher end, more focused applications and technology can build on this and grow.

Q9: What are the options for how public sector organisations could continue to invest in maintaining and enhancing our geospatial data assets?

We see this happening already with merging of OS ITN with the NSG. This type of harmonisation is painful for all involved, but it's been a long time coming. Identifying and continuing to thrash out the differences between the major datasets being managed and maintained in different public-sector organisations will benefit all and make the higher end products and processes more achievable.

Q10: What areas of the underpinning geospatial infrastructure such as positioning technologies, including GPS and indoor positioning systems, and geodetic networks and frameworks to support them, should we be prioritising the development of, in order to support the emerging requirements for geospatial data?

Most systems can now user a mixture of remote sensed positional information such as GPS, GLONASS etc. making for accurate locational information. The question is when is this not good enough and how can this be improved. Post processing is fine for asset inventory but it's no good for live on demand services where fixed sensors that have known points can send out coordinates, e. g. About to dig a hole into a mix of buried assets.

Q11: What role should the private sector have in both the development and maintenance of the underpinning infrastructure and enhancing the UK's geospatial data assets?

A mandate to share data to help facilitate a fully-fledged buried assets layer of the Uk.

Some progress is being made for example a pilot being led up North: called the Northeast Underground Infrastructure Hub – a pilot to ship and clip buried assets on demand between utilities and Local Authorities to avoid strikes/damage to buried assets. Stakeholders include the DNO's Gas, Water, LA's and Broad band operators.

Q12. Do you face challenges when working with geospatial data from across the public sector? If so, what are they and how could value be better released? Are there any technical remedies or standards that could be adopted to improve the interoperability of geospatial data? Please provide supporting evidence of what these remedies could help to accomplish.

Around 80% of any GI project is spent on data preparation. The analysis and reporting are the easy bit. Access to Metadata in any standard would be useful but it's a rarity. – a data dictionary with a date is hard enough to maintain.

Q13. How can the Geospatial Commission act as a more effective customer for geospatial data on behalf of the public sector?

Q14. Are there any additional geospatial datasets, from the other partner bodies or other sources, that the public sector would derive significant benefit from having access to, that might have novel and valuable use cases? What would that access look like?

Land Registry data – but with all the additional attributes that are not currently supplied.

Q15: How can we best develop a single UK strategy, ensuring alignment between the individual strategies across the UK while still allwoing for regional variations?

We could ask you the same question!

Q16: How can we best ensure effective local authority coordination and sharing of best practise, using location data to better deliver public services?

Good luck with that! You will have to implement something like INSPIRE and be prepared to provide funding. LA's are in a state of austerity – they won't deliver any additional burdens placed on them unless these are enshrined in law and funded.

Q17: As a result of this analysis, we are prioritising the exploration of possible initiatives in the high-value categories identified:

- **property and land**
- **infrastructure and construction**
- **mobility**
- **natural resources**
- **sales and marketing**

What are the existing or potential geospatial applications which could be scaled-up or developed in order to capture economic value? (We would particularly welcome responses from industry and other bodies engaged in these sectors.)

Q18: Are there any other areas that we should look at as a priority?

Q19: What are the main potential private and public sector innovations that will rely on the use of geospatial data to rollout, and are there corresponding regulatory challenges?

Q20: How best can we make the UK's presence in the international geospatial world more visible?

Q21: Where should the UK be looking for points of comparison overseas? Who are the other international exemplars? What best practice is being modelled overseas that we can learn from?

Look at Google. They have shown the so-called GIS Experts such as ESRI and MapInfo a thing or two about tech. Who needs a business case to do things! If we build it, they will use 'IT' approach.

I would also say that 'spatial' is not 'special' – it's sometimes different. By making it 'special' you create the silo mentality. Oh, it's something about GIS; which is kind of missing the point. The 'G' needs to become mainstream. That's where it becomes useful. The 'where' tag is just one component of the 5W's https://en.wikipedia.org/wiki/Five_Ws

Thank you for your time in completing your response to our call for evidence.

Any questions, please get in touch with the Geospatial Commission via geospatialcommission@cabinetoffice.gov.uk

Geospatial Commission:
Call For Evidence Response Questionnaire

Please submit your completed questionnaire to:

geospatialcommission@cabinetoffice.gov.uk.

Clearly title your email *'Call for evidence response'*.

Micro business (up to 9)	
Other - please state	

Call for evidence - three key themes

We have identified three high-level themes that could help our approach to setting a strategy which are as follows:

1. **Supporting innovation in the geospatial sector**, exploring how to secure cutting edge skills, the right access to data, and opportunities from emerging technologies for the geospatial sector itself
2. **Enhancing the UK's geospatial assets,** looking at how best to align interests, avoid duplication, and instill best practice across the whole public sector
3. **Driving investment and productivity in geospatial applications**, asking in which wider sectors the most value lies from better exploitation and use of geospatial data, in the UK and internationally

Our questions

Q1. Is our view of the geospatial data types accurate? If not, what should be included or excluded from this?

-

Q2. In addition to current government policy, what are the areas of geospatial skills where the commission could best focus, to help ensure the necessary capability within the UK for the future?

Improved capability in geospatial data handling in the UK in future relies on an educated workforce with technical, engineering and scientific skills. The discipline of geomatics - surveying, mapping, earth observation, GIS, spatial analysis - has been greviously neglected in UK further and higher education for decades. Its importance has not been sufficiently recognised, courses have closed or been marginalised, the gap between ever-growing demands from industry for graduates in the field of geospatial data handling and ever-decreasing supply of well-trained and capable graduates is growing. The resultant 'de-skilling' leads to a vicious circle, of lack of knowledge of what is required and possible from such activity and a lack of appreciation of the level of skill required. There needs to be better direction from professional organisations and government, and more engagement from FE and HE.

Q3. What are the geospatial skills needs and gaps in your organisations, how can these be most effectively addressed, and how can careers in the sector be best promoted?

From the previous comment it might be imagined that promotion of 'geography' at school might be a solution. To me, that is, in fact, a difficulty. Geography is a nebulous subject, delivered to unfocussed students, who have little aptitude in technical aspects and little interest in developing a coherent and value-added core of knowledge and practical ability: it is a 'look-see' discipline, when what is needed is 'getting your hands dirty, and coming up with a deliverable' attitude. It would be more valuable to promote careers in the geospatial sector to engineers, badging 'geospatial engineering' as an activity equal to mechanical or civil engineering. The geospatial skills gaps are in measurement science and rigorous data capture, big data management, integration of technologies (soft- and hard-ware), and geostatistical analysis. The human angle is also required - policy-driven application of GI; study of human-computer interaction (notably for GI, in visualisation); community, infra-structure, and indeed disaster management all require geospatial skills.

Q4. Are there any publicly or privately-held geospatial datasets that are currently challenging to access or use or of insufficient quality, but which you or your organisation would find valuable if these issues could be resolved? Please explain why this would be of value, and how access/quality could be improved?

-

Q5: Do you anticipate that any changes will be needed to the both address data and the wider address ecosystem, to support emerging technologies? Please provide evidence of value to support any proposed changes.

-

Q6: How should the commission be looking to develop the UK's capability in Earth observation data, both technologically and to support an effective market?

-

Q7. Which new technologies should the commission focus on to provide new opportunities to process and exploit geospatial data for economic growth?

This list of new technologies is well-known. The geospatial industry is good at forecasting, but too often the predicted trends are taken on by other sectors, and geospatial finds it difficult to assert its contribution and promote its leadership. 'Driverless vehicles', for example, rely totally on geospatial data for operation, reaction, safety, economy and reliability. BIM drives a standard 'modus operandi' throughout construction, initially developed by geomatics and GIScience. Precision agriculture, 'smart cities', augmented reality, UAVs, location-based services are all exploitable technologies which geospatial must retain or regain control over. Even the insurance industry (pre-eminent in the UK financial services sector) could profitably employ more geospatial expertise, in both domestic and foreigh markets.

Q8. How can geospatial data and applications be used to support enhanced roll-out of future technologies?

-

Q9: What are the options for how public sector organisations could continue to invest in maintaining and enhancing our geospatial data assets?

-

Q10: What areas of the underpinning geospatial infrastructure such as positioning technologies, including GPS and indoor positioning systems, and geodetic networks and frameworks to support them, should we be prioritising the development of, in order to support the emerging requirements for geospatial data?

-

Q11: What role should the private sector have in both the development and maintenance of the underpinning infrastructure and enhancing the UK's geospatial data assets?

-

Q12. Do you face challenges when working with geospatial data from across the public sector? If so, what are they and how could value be better released? Are there any technical remedies or standards that could be adopted to improve the interoperability of geospatial data? Please provide supporting evidence of what these remedies could help to accomplish.

Q13. How can the Geospatial Commission act as a more effective customer for geospatial data on behalf of the public sector?

Q14. Are there any additional geospatial datasets, from the other partner bodies or other sources, that the public sector would derive significant benefit from having access to, that might have novel and valuable use cases? What would that access look like?

The legacy of available, publicly funded, accurate geospatial datasets has been severely damaged by political agendas in recent decades. The decision to disband the Soil Survey of England & Wales is but one example - the dataset is archived, no longer maintained and almost impossible to access. Agricultural censuses, weather data, property registers, election results data, public health information are either no longer systematic, commissioned on a 'one-off' basis, are expensive to access, or are restricted and non-transparent. Crime data is an example of a public sector dataset which is well presented and documented. Temporal and spatial comparability is important, for research and for practical usage of the data. The uncertainty about the operation and administration of the 2021 UK population census does not augur well for an effective, joined-up, government data management strategy.

Q15: How can we best develop a single UK strategy, ensuring alignment between the individual strategies across the UK while still allwoing for regional variations?

-

Q16: How can we best ensure effective local authority coordination and sharing of best practise, using location data to better deliver public services?

From a practical viewpoint, local councils need the resources to do this, rather than having their budgets relentlessly cut in the name of 'austerity'.

Q17: As a result of this analysis, we are prioritising the exploration of possible initiatives in the high-value categories identified:

- **property and land**
- **infrastructure and construction**
- **mobility**
- **natural resources**
- **sales and marketing**

What are the existing or potential geospatial applications which could be scaled-up or developed in order to capture economic value? (We would particularly welcome responses from industry and other bodies engaged in these sectors.)

-

Q18: Are there any other areas that we should look at as a priority?

-

Q19: What are the main potential private and public sector innovations that will rely on the use of geospatial data to rollout, and are there corresponding regulatory challenges?

-

Q20: How best can we make the UK's presence in the international geospatial world more visible?

UK expertise in the the global marketplace was, in the past, evident in the activities of a wide range of hi-tech (at the time) firms who supported both goverment (colonial) projects and capacity support for commercial activities overseas. The days of Hunting Surveys and Fairey Surveys, each with capacity for large integrated geospatial projects are long gone. The skills of DOS were set aside for many years when they integrated with OS several decades ago. The revival of OS International in recent years shows that the UK can still bid for large multi-disciplinary projects. If the UK private sector could be more collaborative then such large-scale capability could be marketed anew. The wide-ranging competencies of Norway's geospatial industry markets Norwegian expertise internationally under the banner of its GeoForum - 46 separate firms in a small country, offering integrated capability. Korea Sweden, Japan etc. also adopt such a collaborative approach to winning business overseas. The UK geospatial industry does itself no favours in valuing itself too cheaply, and being fragmented in outlook.

Q21: Where should the UK be looking for points of comparison overseas? Who are the other international exemplars? What best practice is being modelled overseas that we can learn from?

see answer to Q20 above.

Thank you for your time in completing your response to our call for evidence.

Any questions, please get in touch with the Geospatial Commission via geospatialcommission@cabinetoffice.gov.uk

Geospatial Commission: Call For Evidence Response Questionnaire

Call for evidence - three key themes

We have identified three high-level themes that could help our approach to setting a strategy which are as follows:

1. **Supporting innovation in the geospatial sector**, exploring how to secure cutting edge skills, the right access to data, and opportunities from emerging technologies for the geospatial sector itself
2. **Enhancing the UK's geospatial assets,** looking at how best to align interests, avoid duplication, and instill best practice across the whole public sector
3. **Driving investment and productivity in geospatial applications**, asking in which wider sectors the most value lies from better exploitation and use of geospatial data, in the UK and internationally

Our questions

Q1. Is our view of the geospatial data types accurate? If not, what should be included or excluded from this?

The definition of 'positional data' is completely unclear. Some examples would help.

Q2. In addition to current government policy, what are the areas of geospatial skills where the commission could best focus, to help ensure the necessary capability within the UK for the future?

Skills are needed across all the sensing and positioning technologies (whether terrestrial, airborne, spaceborne or marine) that form the basis of geospatial data collection. This will require skills in fundamental mathematics and physics, and in various branches of engineering, and in aspects of the Earth, atmospheric and marine sciences which are needed to understand the full measurement problem. More should be done to engage practitioners in these fields and encourage migration into geospatial applications of their discplines.

Q3. What are the geospatial skills needs and gaps in your organisations, how can these be most effectively addressed, and how can careers in the sector be best promoted?

We require skills in fundamental mathematics and physics, and in various branches of engineering, and in aspects of the Earth, atmospheric and marine sciences which are needed to understand the measurement problems faced in sensing and positioning technologies. Publicity and resources are needed to promote geospatial further education and careers to students of these subjects at 16+ (or earlier) and at university.
At present there is great difficulty in promoting the geospatial sector, because professionals in the sector are split amongst a wide variety of learned, professional and trade bodies (e.g. RICS, CICES, TSA, GA, RGS, IoN, RAS, GeolSoc, BCS). Although these bodies between them reflect the many aspects of geospatial data use, none of them represents the field as a whole, and this militates against a coherent high-profile effort to raise the profile of the discipline, to campaign for it, and to agree standards.

Q4. Are there any publicly or privately-held geospatial datasets that are currently challenging to access or use or of insufficient quality, but which you or your organisation would find valuable if these issues could be resolved? Please explain why this would be of value, and how access/quality could be improved?

No comment.

Q5: Do you anticipate that any changes will be needed to the both address data and the wider address ecosystem, to support emerging technologies? Please provide evidence of value to support any proposed changes.

The information to translate between different address systems (including global and national coordinate reference frames) is a vital public good. The ability to use this without hindrance will be vital for developing geospatial applications.

Q6: How should the commission be looking to develop the UK's capability in Earth observation data, both technologically and to support an effective market?

In technological terms, more targeted resources are needed for research and development in this area. This will include funding for satellite missions, whether through UKSA or as part of ESA (continued UK membership of ESA, post-Brexit, is important to achieve economies of scale in space missions). Development of an effective market must be based on stable availability of datasets, and/or a predictable transition from subsidised costs at early stages (and for research users) through to fully-commercial development where appropriate.

Q7. Which new technologies should the commission focus on to provide new opportunities to process and exploit geospatial data for economic growth?

No comment.

Q8. How can geospatial data and applications be used to support enhanced roll-out of future technologies?

No comment.

Q9: What are the options for how public sector organisations could continue to invest in maintaining and enhancing our geospatial data assets?

These assets are an important public good, and their maintenance using public funds is a necessary support for the commercial geospatial sector, and a means of ensuring common (and exacting) adoption of standards.

Q10: What areas of the underpinning geospatial infrastructure such as positioning technologies, including GPS and indoor positioning systems, and geodetic networks and frameworks to support them, should we be prioritising the development of, in order to support the emerging requirements for geospatial data?

Maintenance of GNSS reference station networks provides access to national and international reference frames which are vital geodetic infrastructure. Other positioning technologies (e.g. e-Loran, indoor positioning) are needed as backup and for particular environments. However, with the proliferation of GNSS satellites (space segments) there should be no question of diverting large amounts of resource towards a separate UK GNSS space segment.

Q11: What role should the private sector have in both the development and maintenance of the underpinning infrastructure and enhancing the UK's geospatial data assets?

No comment.

Q12. Do you face challenges when working with geospatial data from across the public sector? If so, what are they and how could value be better released? Are there any technical remedies or standards that could be adopted to improve the interoperability of geospatial data? Please provide supporting evidence of what these remedies could help to accomplish.

No comment.

Q13. How can the Geospatial Commission act as a more effective customer for geospatial data on behalf of the public sector?

By ensuring that all data, once obtained for the public, is available to the public.

Q14. Are there any additional geospatial datasets, from the other partner bodies or other sources, that the public sector would derive significant benefit from having access to, that might have novel and valuable use cases? What would that access look like?

No comment.

Q15: How can we best develop a single UK strategy, ensuring alignment between the individual strategies across the UK while still allwoing for regional variations?

Through the use of common data and metadata standards, regional strategies can be allowed to overlay or substitute aspects of a national strategy.

Q16: How can we best ensure effective local authority coordination and sharing of best practise, using location data to better deliver public services?

Again, the use of common data and metadata standards will allow common approaches to be applied to specific applications and datasets.

Q17: As a result of this analysis, we are prioritising the exploration of possible initiatives in the high-value categories identified:

- **property and land**
- **infrastructure and construction**
- **mobility**
- **natural resources**
- **sales and marketing**

What are the existing or potential geospatial applications which could be scaled-up or developed in order to capture economic value? (We would particularly welcome responses from industry and other bodies engaged in these sectors.)

No comment.

Q18: Are there any other areas that we should look at as a priority?

No comment.

Q19: What are the main potential private and public sector innovations that will rely on the use of geospatial data to rollout, and are there corresponding regulatory challenges?

No comment.

Q20: How best can we make the UK's presence in the international geospatial world more visible?

As mentioned previously, at present there is great difficulty in promoting the UK geospatial sector because professionals in the sector are split amongst a wide variety of learned, professional and trade bodies (e.g. RICS, CICES, TSA, GA, RGS, IoN, RAS, GeolSoc, BCS). Although these bodies between them reflect the many aspects of geospatial data use, none of them represents the field as a whole, and this militates against a coherent high-profile effort to raise the profile of the discipline, to campaign for it, and to agree standards.

Q21: Where should the UK be looking for points of comparison overseas? Who are the other international exemplars? What best practice is being modelled overseas that we can learn from?

UNGGIM.

Thank you for your time in completing your response to our call for evidence.

Any questions, please get in touch with the Geospatial Commission via geospatialcommission@cabinetoffice.gov.uk

Geospatial Commission: Call For Evidence Response Questionnaire

Call for evidence - three key themes

We have identified three high-level themes that could help our approach to setting a strategy which are as follows:

1. **Supporting innovation in the geospatial sector**, exploring how to secure cutting edge skills, the right access to data, and opportunities from emerging technologies for the geospatial sector itself
2. **Enhancing the UK's geospatial assets,** looking at how best to align interests, avoid duplication, and instill best practice across the whole public sector
3. **Driving investment and productivity in geospatial applications**, asking in which wider sectors the most value lies from better exploitation and use of geospatial data, in the UK and internationally

Our questions

Q1. Is our view of the geospatial data types accurate? If not, what should be included or excluded from this?

Data derived from the internet of things is specifically geolocated (or moving) but is often overlooked as spatial data as IoT is seen (incorrectly) as a computing science and technology issue. Place, space and location are embedded within how we conceptualise and use IoT data but not usually considered spatial data.

I would expand this list to include information that is currently not available but will be such as those being derived from CAVs and related infrastructure. The danger here is that it is corralled and ring fenced from public use by manufacturers and other (transportation industry) players.

Q2. In addition to current government policy, what are the areas of geospatial skills where the commission could best focus, to help ensure the necessary capability within the UK for the future?

There is a woeful lack of geospatial training at tertiary levels in the UK. We currently have very few instistitutions that develop analytical skills in geospatial measurement, management and analytics. (Compared with other countries and especially the emerging economies of India and China). I suspect there are less that 150 University trained Geospatial (at UG and MSc level).
There is a big skills gap between employment opportunities and availability of people to fill those opportunities from the technoloigy and digital sector all the way to oil and gas and construction.

Q3. What are the geospatial skills needs and gaps in your organisations, how can these be most effectively addressed, and how can careers in the sector be best promoted?

We are in the privileged position of offering the only UK undergraduate course in Surveying and Mapping and GIS. Nevertheless addressing the skills shortage requires the embedding of spatial literacy within our schools curriculum and realising and championing the skills of geospatial analysts. They should be as ubiquitous as statisticians (and valued) but are not and there is a need to embed spatial thinking and problem solving (as well as practical data handling skills) into other disciplines.

Q4. Are there any publicly or privately-held geospatial datasets that are currently challenging to access or use or of insufficient quality, but which you or your organisation would find valuable if these issues could be resolved? Please explain why this would be of value, and how access/quality could be improved?

Too many to mention. The moves to open data are a great step forward but it is a very complicated licensing, copyright and reuse landscape. Concerns here are more focussed on the private sector who consider spatial data as a monetary asset to be exploited through other services (Strava, Google, TomTom etc.). For use in such things as transport planning, urban analytics and simulation, access to geospatial data from non gov't sources is potentially key. Private data firms will be the key data holders in the near future (some already are). The move towards CAVs and other singularities (car on demand etc.) puts potentially critical datasets in the hands solely into private companies.

The issue is not just about data provision – mechanisms for timeliness of provision, upkeep and maintenance that all have a cost must be addressed. Ie. It is not enough to get a data dump as a one-off – it must be process based and ongoing. A key commitment to open-data through government contract and

licensing arrangements may be a way of passing the cost onto the operator and ensuring longer term solutions.

Mobile phone data could be a huge asset for research and planning.

Q5: Do you anticipate that any changes will be needed to the both address data and the wider address ecosystem, to support emerging technologies? Please provide evidence of value to support any proposed changes.

Q6: How should the commission be looking to develop the UK's capability in Earth observation data, both technologically and to support an effective market?

Access is the key. Make it discoverable, visible and usable. Consider deploying data as services rather than files or products. Create SLAs for data delivery to encourage commercial use. Give open access to education and non commercial use to encourage training and understanding.

Q7. Which new technologies should the commission focus on to provide new opportunities to process and exploit geospatial data for economic growth?

I don't think the emphasis should be on technology. It should be on methods for
1. data access
2. data provenance
3. commitment to openness
4. services rather than products
5. agility over completeness

Q8. How can geospatial data and applications be used to support enhanced roll-out of future technologies?

Geospatial data (and the associated analytics) underpin many new technologies (AR, CAV, IoT to name a few) – they already implicitly are geospatial and interact with geospatial. They are not seen as geospatial problems and geospatial but technologies and data from the geospatial realm is absolutely there. The fact that we are asking this question is rather revealing as it assumes that geospatial is not ALREADY embedded. Therefore we need sustainable data delivery systems, pricing etc. to support it. These should be a revenue stream for better data and data integration from government data providers.

Q9: What are the options for how public sector organisations could continue to invest in maintaining and enhancing our geospatial data assets?

1. Make it open and and ger revenue from innovation and growth in sectors that use it (hard to pin value and not market driven)
2. Be more agile in how data is delivered and charged for (and who gets charged)
3. The local authorities have a key role here (esp in urban data) but they have been stripped of skills (in Newcastle for instance the spatial team has gone from 8 people to 0.5 people over the past few years). Mapping and geospatial is not seen as essential.
4. Work with technology partners more directly as a key data provider

Q10: What areas of the underpinning geospatial infrastructure such as positioning technologies, including GPS and indoor positioning systems, and geodetic networks and frameworks to support them, should we be prioritising the development of, in order to support the emerging requirements for geospatial data?

Not my are of expertise but a national open GNSS correction facility would be useful.

Q11: What role should the private sector have in both the development and maintenance of the underpinning infrastructure and enhancing the UK's geospatial data assets?

They already do, most don't share it though. Most of us use google services that effectively bypasses national data assets. Google (and others) are a useful delivery programme. If they are out of the loop they will develop alternate data sets (that may be inferior but will be widely used)

Q12. Do you face challenges when working with geospatial data from across the public sector? If so, what are they and how could value be better released? Are there any technical remedies or standards that could be adopted to improve the interoperability of geospatial data? Please provide supporting evidence of what these remedies could help to accomplish.

It's a very mixed bag. I really really don't think we should stress on standards – they are already there – but it needs variety as well as there are as many use cases for the data as there organisations using it. One size does not fit all. An agile approach with data being able to be accessed, queried and utilisied through many different lenses (quality, attributes, scale, function, location) is what we need. Technology moves so fast that principles and openness are more important than standards.

Q13. How can the Geospatial Commission act as a more effective customer for geospatial data on behalf of the public sector?

Provide leadership, vision and direction of travel. Use clout to enable access to data generated by commercial entities for the public good. Create a socio-technical ecosystem that enables data accessibility in an ongoing fashion. Be clear that today's solutions may not be applicable in 12 months time.

Invest in skills and develop these from the bottom up through from schools to universities and in the work place.

Q14. Are there any additional geospatial datasets, from the other partner bodies or other sources, that the public sector would derive significant benefit from having access to, that might have novel and valuable use cases? What would that access look like?

Mobile phone data – transport planning and analytics, fine scale movement patterns.
Data.gov.uk is a good start but clumsily executed for spatial data.

Q15: How can we best develop a single UK strategy, ensuring alignment between the individual strategies across the UK while still allwoing for regional variations?

Encourage funding for spatial data specialists (data, analysis and visualisation) in regional and local government. They have been decimated.

Q16: How can we best ensure effective local authority coordination and sharing of best practise, using location data to better deliver public services?

Encourage funding for spatial data specialists (data, analysis and visualisation) in regional and local government. They have been decimated.

Have a pipeline of skilled practitioners to supprt

Q17: As a result of this analysis, we are prioritising the exploration of possible initiatives in the high-value categories identified:

- **property and land**
- **infrastructure and construction**
- **mobility**
- **natural resources**
- **sales and marketing**

What are the existing or potential geospatial applications which could be scaled-up or developed in order to capture economic value? (We would particularly welcome responses from industry and other bodies engaged in these sectors.)

Q18: Are there any other areas that we should look at as a priority?

I think CAV is a game changer both in the quantity of data generated and required.
IoT – an inherently spatial issue that is not seen as such.

Q19: What are the main potential private and public sector innovations that will rely on the use of geospatial data to rollout, and are there corresponding regulatory challenges?

Data governance and data security is something that transcends sectors. IoT, CAV, Smart Cities are all dependent on the same set of technologies, protocols and semi standards.

Q20: How best can we make the UK's presence in the international geospatial world more visible?

Invest in the education sector. Ensure that it is seen as a profession with value.

Q21: Where should the UK be looking for points of comparison overseas? Who are the other international exemplars? What best practice is being modelled overseas that we can learn from?

Geospatial Commission: Call For Evidence Response Questionnaire

Call for evidence - three key themes

We have identified three high-level themes that could help our approach to setting a strategy which are as follows:

1. **Supporting innovation in the geospatial sector**, exploring how to secure cutting edge skills, the right access to data, and opportunities from emerging technologies for the geospatial sector itself
2. **Enhancing the UK's geospatial assets,** looking at how best to align interests, avoid duplication, and instill best practice across the whole public sector
3. **Driving investment and productivity in geospatial applications**, asking in which wider sectors the most value lies from better exploitation and use of geospatial data, in the UK and internationally

Our questions

Q1. Is our view of the geospatial data types accurate? If not, what should be included or excluded from this?

Yes

Q2. In addition to current government policy, what are the areas of geospatial skills where the commission could best focus, to help ensure the necessary capability within the UK for the future?

Appreciation of the added value that openness, transparency and accountability, bring, as well as the capacity and involvement of citizens in the process. Regional coordination and balance, to avoid the mistake of piecemeal approaches adopted in the past leading to differences in service delivery and making inter-regional trade in expertise and service provision a challenge. A greater focus on what can be done with the data, rather than (solely) the existence and detail in the data itself.

Q3. What are the geospatial skills needs and gaps in your organisations, how can these be most effectively addressed, and how can careers in the sector be best promoted?

In general, the availability and quality of open geospatial (and locational) data in **Northern Ireland is not on par with equivalent data across the UK.**

This acts as a **significant barrier to entry** for developers, business and end-users based in Northern Ireland or providing services to our citizens.

Governance of the Ordnance Survey Northern Ireland (OSNI) differs from that of OS in GB, and they have operated as separate entities since 1922. While OSGB is an *independent* non-ministerial government department with Executive Agency status, OSNI itself is simply a part of the NI Department of Finance's internal branch Land and Property Service (LPS). The Department of Finance therefore, in effect, has control over the availability and licensing of a number of strategically important geospatial datasets.

OSNI/LPS concerns about 'derived data' in turn **restricts the publication and licensing of other government departments' and public bodies' production of open geospatial and locational data**, even in cases where the impact would be insubstantial.

A National Geospatial Strategy must therefore be cognisant of the current **discrepancy in the availability, transparency and accountability of geospatial information assets in Northern Ireland**, and must seek to **address these limitations in a material way**, otherwise the economic opportunity that exists will not be delivered equally to all citizens.

Q4. Are there any publicly or privately-held geospatial datasets that are currently challenging to access or use or of insufficient quality, but which you or your organisation would find valuable if these issues could be resolved? Please explain why this would be of value, and how access/quality could be improved?

In particular, organisations and individuals in Northern Ireland are greatly disadvantaged by the **lack of a free, openly licensed postcode or address geolocation data,** seemingly due to a different funding situation with respect to Royal Mail's Postcode Address File. Use of the NI postcodes requires users to pay a substantial fee.

The fact is that it is not possible to perform a lookup operation on a postcode to determine a geographical location using well-maintained, purportedly accurate and official database under an Open Government Licence. This has **obvious and significant drawbacks** for the potential users and beneficiaries of this basic functionality as the licensing is not interoperable with, or on par with, the rest of the UK.

Access and positive impact could be greatly improved by **openly licensing the Northern Ireland Central Postcode Database**.

Q5: Do you anticipate that any changes will be needed to the both address data and the wider address ecosystem, to support emerging technologies? Please provide evidence of value to support any proposed changes.

See response Q4

We believe that there is a great deal of potential to be gained from openly-licensed spatial, geographic and property data which would bring significant economic and social value through the development of new products and services, innovative solutions to existing problems, and better access to information.

Q9: What are the options for how public sector organisations could continue to invest in maintaining and enhancing our geospatial data assets?

Adherence to open standards in procurement pipelines will lead to sustainable maintenance of assets without 'vendor lock-in', encouraging growth in specialised geospatial data processing SMEs.

Q11: What role should the private sector have in both the development and maintenance of the underpinning infrastructure and enhancing the UK's geospatial data assets?

Engagement with producers of national and regional (i.e. devolved) geospatial data assets in an open, transparent and participatory manner, and through contributing to the improvement of the quality of these assets.

Such engagement and participation should go beyond the immediate actors in the geospatial industry, and should also **involve citizens and organisations outside of the private sector**.

This engagement should occur **at a regional level, with local authorities and devolved administrations as well as the UK bodies**.

Q12. Do you face challenges when working with geospatial data from across the public sector? If so, what are they and how could value be better released? Are there any technical remedies or standards that could be adopted to improve the interoperability of geospatial data? Please provide supporting evidence of what these remedies could help to accomplish.

Previous response have highlighted the challenge of working with geospatial data in Northern Ireland on an equivalent basis to other areas in the UK.

Value could be better realised through **aiming to achieve parity across the UK** in the availability, openness and quality of geospatial data**.**

Interoperability of data licensing is as important an issue as technical interoperability for data users. As a general rule, licensing interoperability is best addressed through the **consistent adoption of the Open Government License** across all parts of the UK, and for as many types of spatial data as possible.

Q13. How can the Geospatial Commission act as a more effective customer for geospatial data on behalf of the public sector?

The Geospatial Commission can **identify regional imbalances which exist** due to either a differing approach or differences in need for particular geospatial data assets, and press for action to address the problems that this creates.

Q14. Are there any additional geospatial datasets, from the other partner bodies or other sources, that the public sector would derive significant benefit from having access to, that might have novel and valuable use cases? What would that access look like?

Comparative land registry and house price data is not accessible in Northern Ireland.

Cadastral data ('land packets') is also in short supply locally.

Land registry, domestic and non-domestic property data, including building types, size, valuation, land area, outbuildings, etc. both in tabular and GIS formats. This may form part of planning data held by other government departments.

Orthophotography. There are a number of historic orthophotographic datasets that are not the current version sold by OSNI as they have been produced in various waves (around 5) since 2006. Near-infrared imagery is also useful for quantifying vegetation coverage and health for agricultural and ecological purposes. While not commercially useful to OSNI, the historic photography from the older orthophotography could still be useful in a number of applications, particularly those with an interest in urban development, built heritage, environmental protection.

Q15: How can we best develop a single UK strategy, ensuring alignment between the individual strategies across the UK while still allwoing for regional variations?

Previous responses have made reference to the challenge of working with geospatial data in Northern Ireland, and value could be better realised through **aiming to achieve parity across the UK** in the availability, openness and quality of geospatial data**.**

'Regional variations', in a national strategy context, should account for need, rather than being dependent on (and therefore restricted by) the ability or willingness of necessary parties to participate.

It is also relevant (and timely) to note that Northern Ireland faces significant challenges in its status and economic position due to Brexit, and that the somewhat lack of existence of innovative responses to these mounting problems, on the whole, **cannot be addressed by ignoring the areas in which the potential for developing new markets and solutions could be realised**.

Thank you for your time in completing your response to our call for evidence.

Any questions, please get in touch with the Geospatial Commission via geospatialcommission@cabinetoffice.gov.uk

Geospatial Commission: Call For Evidence Response Questionnaire

Please submit your completed questionnaire to:

geospatialcommission@cabinetoffice.gov.uk.

Clearly title your email *'Call for evidence response'*.

About you and your organisation

Name	[Text redacted]
Organisation	North Somerset Council
Job title	[Text redacted]
Address	[Text redacted]
E-mail	[Text redacted]
Telephone	[Text redacted]

Please select which of the following best describes you as a respondent:

Respondent	**Please mark with a X**
Academic	
Business representative / trade body	
Central government	
Charity or social enterprise	
Individual	
Legal representative	
Local government	**X**
Large business (over 250 staff)	
Medium business (50 to 250)	
Small business (10 to 49)	
Micro business (up to 9)	

Other - please state	

Call for evidence - three key themes

We have identified three high-level themes that could help our approach to setting a strategy which are as follows:

1. **Supporting innovation in the geospatial sector**, exploring how to secure cutting edge skills, the right access to data, and opportunities from emerging technologies for the geospatial sector itself
2. **Enhancing the UK's geospatial assets,** looking at how best to align interests, avoid duplication, and instill best practice across the whole public sector
3. **Driving investment and productivity in geospatial applications**, asking in which wider sectors the most value lies from better exploitation and use of geospatial data, in the UK and internationally

Our questions

Q1. Is our view of the geospatial data types accurate? If not, what should be included or excluded from this?

Nothing to add

Q2. In addition to current government policy, what are the areas of geospatial skills where the commission could best focus, to help ensure the necessary capability within the UK for the future?

Nothing to add

Q3. What are the geospatial skills needs and gaps in your organisations, how can these be most effectively addressed, and how can careers in the sector be best promoted?

Make senior managers and decision makers aware of the existence and benefits to the organisation of spatial data. As a result of this hopefully further resources will be allocated towards the development of geospatial data and staff can be given the opportunity to stay up to date with changes in the industry and develop their skills (for example obtaining CGeogGI status). At the moment there is no time and little money/budget to obtain these credentials.

Q4. Are there any publicly or privately-held geospatial datasets that are currently challenging to access or use or of insufficient quality, but which you or your organisation would find valuable if these issues could be resolved? Please explain why this would be of value, and how access/quality could be improved?

Currently the council has to pay for access to British Geological Survey data. Our Flooding Team uses this data in order to assess flooding risks. It would be helpful if we could receive this data free of charge.

It would be helpful if we could get access to Land Registry data as this would enable us to more quickly find out ownership information which would enable large council infrastructure projects to progress faster and more efficiently. At the moment we have to pay for these searches, but it would be even better if we could access this data free of charge.

In terms of street naming and numbering allocations it would be useful to be able to interrogate the MPAN database in order to check for any duplicate numbers/property names prior to allocating new addresses. At the moment this address information is unobtainable.

Satellite navigation systems and certain private mapping providers such as Google do not consult with Local Authorities with regards to road types and road names. A recent example of this is the naming of a new bus link road which Google have added to their map as Feeder Road when the official name is Longmoor Way. There is no easy and quick way to make Google aware of these errors which is frustrating. Also, in terms of Highways data Feeder Road which is accessible to buses and emergency vehicles only was listed as open to local traffic, buses, towed caravans, trailers and motorhomes on Here maps' database. We need improved channels of communication with these private organisations so that the data that they hold is always accurate. Inaccurate third party content causes additional issues for Local Authorities in terms of increased queries and resolving otherwise unavoidable issues. Google especially seem to decide whether they want to accept my suggested modifications leaving incorrect data in the public domain for as long as they wish.

The e-PIMS website is a good idea however the data could be up to six months out of date which means that it is unusable. The data is represented by points and not polygons therefore the information that is there is not only potentially out of date but not very meaningful either. Please can this website be improved as it has a lot of potential.

Q5: Do you anticipate that any changes will be needed to the both address data and the wider address ecosystem, to support emerging technologies? Please provide evidence of value to support any proposed changes.

The UPRN and BLPU need to be made freely available along with its various LPIs e.g. approved address, alternative address, historic address. Current licensing issues stops us from making this information available and therefore the wider public and third party private sector companies are not aware of its existence.

Street naming and numbering requires new, clear legislation which especially clarifies whether councils can charge for the provision of the service and how the address allocation process should take place. It also needs to be made clearer that Local Authorities issue addresses and it is not the property owner's duty to allocate their own version of the address. Unofficial addresses cause issues going forward in terms of them not being listed on external databases, future tenants experiencing issues with their credit rating etc. Unofficially allocated addresses often become embedded and therefore changing them at a later stage can often generate more confusion and hence this cannot be done.

The ownership of the postcode by Royal Mail causes issues. Also, the way in which postcodes are being used today is not what they were designed for e.g. using postcodes in sat navs. An alternative to postcodes needs to be developed which is more fit for purpose and means that addresses will be free from any Royal Mail copyright issues.

Local Authorities experience issues with the fact that the public are more likely to see Royal Mail's version of their address than the council's. Because of this the

public believe that the council's version of their address is incorrect. One of the biggest anomalies between the two datasets (council and Royal Mail) are that the council's version of the address must refer to a street, however especially in rural areas Royal Mail don't refer to streets and instead refer to localities. The council's addresses are geographical whereas Royal Mail's are for the delivery of mail.

The link to Royal Mail and the power that they hold over how addresses are shown on their database (e.g. the multi occupancy database and alternative records) is especially restrictive to Local Authorities and also creates confusion for the public.

Q6: How should the commission be looking to develop the UK's capability in Earth observation data, both technologically and to support an effective market?

If the UK is to lose access to Copernicus data from the EU, we should start looking into a replacement or find a way to remain a part of the Copernicus program.

Examples of data currently provided by Copernicus that are useful for UK economic growth (by informing decisions) are optical land imagery (for emergency services), atmospheric data such as weather, infrared imagery and other land data such as nitrogen saturation (for food production/growth predictions and monitoring) and altimetry (for development of land and navigation).

Q7. Which new technologies should the commission focus on to provide new opportunities to process and exploit geospatial data for economic growth?

Drones, autonomous vehicles

Q8. How can geospatial data and applications be used to support enhanced roll-out of future technologies?

Using the UPRN as a unique identifying feature. ESU points/lines used as an aid to navigation for autonomous vehicles.

Q9: What are the options for how public sector organisations could continue to invest in maintaining and enhancing our geospatial data assets?

Subject to support being offered and an acceptable timescale being in place it would benefit others if all Local Authorities worked to a standard dataset format for key datasets such as highways and street lights. Therefore, if for example Highways England needed to combine all Local Authorities Highways datasets this could be easily achieved.

Provide better awareness and funding of geospatial departments so that time can be invested in streamlining procedures and creating efficiencies rather than just processing data as per business as usual.

Better funding would enable Local Authorities to purchase new technologies or attend courses where staff would glean better skills to enhance the maintenance and improvement of our geospatial data.

Q10: What areas of the underpinning geospatial infrastructure such as positioning technologies, including GPS and indoor positioning systems, and geodetic networks and frameworks to support them, should we be prioritising the development of, in order to support the emerging requirements for geospatial data?

Nothing to add

Q11: What role should the private sector have in both the development and maintenance of the underpinning infrastructure and enhancing the UK's geospatial data assets?

Make data sharing easier between public and private organisations. At the moment sharing data which has been derived from Ordnance Survey data or which contains a UPRN or any reference to PAF is difficult. The private sector should make data sharing easier.

Q12. Do you face challenges when working with geospatial data from across the public sector? If so, what are they and how could value be better released? Are there any technical remedies or standards that could be adopted to improve the interoperability of geospatial data? Please provide supporting evidence of what these remedies could help to accomplish.

Subject to support being offered and an acceptable timescale being put in place it would benefit others if all Local Authorities worked to a standard dataset format for key datasets such as highways and street lights. Therefore, if for example Highways England needed to combine all Local Authorities Highways datasets this could be more easily achieved.

Q13. How can the Geospatial Commission act as a more effective customer for geospatial data on behalf of the public sector?

Nothing to add

Q14. Are there any additional geospatial datasets, from the other partner bodies or other sources, that the public sector would derive significant benefit from having access to, that might have novel and valuable use cases? What would that access look like?

Please refer to question 4

Q15: How can we best develop a single UK strategy, ensuring alignment between the individual strategies across the UK while still allwoing for regional variations?

Nothing to add

Q16: How can we best ensure effective local authority coordination and sharing of best practise, using location data to better deliver public services?

Maintain annual, free PSMA and Geoplace conferences

Q17: As a result of this analysis, we are prioritising the exploration of possible initiatives in the high-value categories identified:

- **property and land**
- **infrastructure and construction**
- **mobility**
- **natural resources**
- **sales and marketing**

What are the existing or potential geospatial applications which could be scaled-up or developed in order to capture economic value? (We would particularly welcome responses from industry and other bodies engaged in these sectors.)

Nothing to add

Q18: Are there any other areas that we should look at as a priority?

Nothing to add

Q19: What are the main potential private and public sector innovations that will rely on the use of geospatial data to rollout, and are there corresponding regulatory challenges?

Drones, autonomous vehicles

Q20: How best can we make the UK's presence in the international geospatial world more visible?

Better communication and marketing

Q21: Where should the UK be looking for points of comparison overseas? Who are the other international exemplars? What best practice is being modelled overseas that we can learn from?

Nothing to add

Geospatial Commission: Call For Evidence Response Questionnaire

Please submit your completed questionnaire to:

geospatialcommission@cabinetoffice.gov.uk.

Clearly title your email *'Call for evidence response'*.

About you and your organisation

Large business (over 250 staff)	
Medium business (50 to 250)	
Small business (10 to 49)	
Micro business (up to 9)	

Other - please state	**Emergency Service**

Call for evidence - three key themes

We have identified three high-level themes that could help our approach to setting a strategy which are as follows:

1. **Supporting innovation in the geospatial sector**, exploring how to secure cutting edge skills, the right access to data, and opportunities from emerging technologies for the geospatial sector itself
2. **Enhancing the UK's geospatial assets,** looking at how best to align interests, avoid duplication, and instill best practice across the whole public sector
3. **Driving investment and productivity in geospatial applications**, asking in which wider sectors the most value lies from better exploitation and use of geospatial data, in the UK and internationally

Our questions

Q1. Is our view of the geospatial data types accurate? If not, what should be included or excluded from this?

Ensuring that Geo Standards used are as open as possible. Avoid proprietary formats whenever possible.

Providing a repository for National Datasets that are updated by the relevant Single Source of Truth centrally and available to all.

Q2. In addition to current government policy, what are the areas of geospatial skills where the commission could best focus, to help ensure the necessary capability within the UK for the future?

Ensure UK has access to Satellite Navigation System.

Q3. What are the geospatial skills needs and gaps in your organisations, how can these be most effectively addressed, and how can careers in the sector be best promoted?

Within Policing, whilst everyone understands the need for effective mapping and gazatteer products, there is little understanding of how the functions are deliverd and maintained. The common (but annoying) expression of, “It’s just an address.” is often heard.

The College of Policing and Police Officer/PCSO training should include at least a dedicated section on addressing and mapping and specialist training should then include extra training on available technologies.

Education should start at Primary School level regarding Geo.

Q4. Are there any publicly or privately-held geospatial datasets that are currently challenging to access or use or of insufficient quality, but which you or your organisation would find valuable if these issues could be resolved? Please explain why this would be of value, and how access/quality could be improved?

Phone box information is provided by BT when requested, however this is only on request. If this information was available to download at any time, with a defined update cycle, it would benefit all.

Road speed information, there is a large gap between the accuracy of posted speed limit signs and the legal document that defines the start and end of speed limit variations.

Q5: Do you anticipate that any changes will be needed to the both address data and the wider address ecosystem, to support emerging technologies? Please provide evidence of value to support any proposed changes.

If Standards are introduced that incorporate the main elements of Geo referencing, and addressing then it becomes easier for the data to be consumed in a consistent way.

Q6: How should the commission be looking to develop the UK's capability in Earth observation data, both technologically and to support an effective market?

Ensure Galleleo or similar is available.

Q7. Which new technologies should the commission focus on to provide new opportunities to process and exploit geospatial data for economic growth?

Do not focus on technologies, focus on data standards that will allow the data to be exploited by those technologies.

Q8. How can geospatial data and applications be used to support enhanced roll-out of future technologies?

Allowing the most open policies to give free reign to individuals to innovate and develop systems and applications.

Q9: What are the options for how public sector organisations could continue to invest in maintaining and enhancing our geospatial data assets?

Resources (both human and financial) are required.

Q10: What areas of the underpinning geospatial infrastructure such as positioning technologies, including GPS and indoor positioning systems, and geodetic networks and frameworks to support them, should we be prioritising the development of, in order to support the emerging requirements for geospatial data?

The ones that have the support of industry.

Q11: What role should the private sector have in both the development and maintenance of the underpinning infrastructure and enhancing the UK's geospatial data assets?

As most innovation comes from the private sector, they should be involved.

Q12. Do you face challenges when working with geospatial data from across the public sector? If so, what are they and how could value be better released? Are there any technical remedies or standards that could be adopted to improve the interoperability of geospatial data? Please provide supporting evidence of what these remedies could help to accomplish.

The recent introduction of Imagery into the PSMA has had an incredibly positive effect. This dataset was previously prohibitively expensive for our organisation to justify as most of the benefits are very hard to financially quantify.

The continued IP and copyright issues of both Postcodes and UPRN with Eastings/Northings inhibits the wider adoption of the UPRN as a referencing key.

Q13. How can the Geospatial Commission act as a more effective customer for geospatial data on behalf of the public sector?

By acting as single procurement agency.

Q14. Are there any additional geospatial datasets, from the other partner bodies or other sources, that the public sector would derive significant benefit

from having access to, that might have novel and valuable use cases? What would that access look like?

3D cities.

Q15: How can we best develop a single UK strategy, ensuring alignment between the individual strategies across the UK while still allwoing for regional variations?

By defining standards that take into account the regional variations. IE '2nd Language' fields.

Q16: How can we best ensure effective local authority coordination and sharing of best practise, using location data to better deliver public services?

This probably relies on effective resourcing, but also increased access to data requires that there are effective mechanisms to keep the data current. Each data set should have a clearly defined schema to accommodate additions, amendments and deletions.

Q17: As a result of this analysis, we are prioritising the exploration of possible initiatives in the high-value categories identified:

- **property and land**
- **infrastructure and construction**
- **mobility**

- **natural resources**
- **sales and marketing**

What are the existing or potential geospatial applications which could be scaled-up or developed in order to capture economic value? (We would particularly welcome responses from industry and other bodies engaged in these sectors.)

Infrastructure to include Roads and the information to deliver smart vehicles and smart cities.

Q18: Are there any other areas that we should look at as a priority?

The opening up of geospatial data will expose the data to a greater critical audience. There should be an avenue by which users of the data can feed back errors & omissions in a timely manner and these should be acted upon to increase the currency, accuracy and detail of the geospatial data.

Q19: What are the main potential private and public sector innovations that will rely on the use of geospatial data to rollout, and are there corresponding regulatory challenges?

Smart Roads, Smart Cities.
Citizen centric service delivery.

Update of the archaic SNN legislation and include a much more robust enforcement of prominent building number display.

Q20: How best can we make the UK's presence in the international geospatial world more visible?

Q21: Where should the UK be looking for points of comparison overseas? Who are the other international exemplars? What best practice is being modelled overseas that we can learn from?

Thank you for your time in completing your response to our call for evidence.

Any questions, please get in touch with the Geospatial Commission via geospatialcommission@cabinetoffice.gov.uk

Call for evidence - three key themes

We have identified three high-level themes that could help our approach to setting a strategy which are as follows:

1. **Supporting innovation in the geospatial sector**, exploring how to secure cutting edge skills, the right access to data, and opportunities from emerging technologies for the geospatial sector itself
2. **Enhancing the UK's geospatial assets,** looking at how best to align interests, avoid duplication, and instill best practice across the whole public sector
3. **Driving investment and productivity in geospatial applications**, asking in which wider sectors the most value lies from better exploitation and use of geospatial data, in the UK and internationally

Our questions

Q1. Is our view of the geospatial data types accurate? If not, what should be included or excluded from this?

We include all spatially organised data within this definition; coming from satellites, aircraft, drones, sensors on the ground and in the sea, probes in the atmosphere, data related to satellite positioning and navigation and all data collected using the full range of surveying techniques, including crowd sourcing, as well as data that is put together using various techniques that can be grouped under the heading GIS.

Q2. In addition to current government policy, what are the areas of geospatial skills where the commission could best focus, to help ensure the necessary capability within the UK for the future?

In the light of Brexit and UK national security we should ensure UK academia is well resourced and well funded to provide people with the Geospatial skills for the future, including GNSS and specialised Earth Observation, such as novel InSAR techniques originating in the UK like ISBAS, as well as a good understanding of the many application areas that geospatial data can service.

The teaching of these undergraduate and postgraduate students should also be complemented by the promotion, provision and full professional accreditation of Continuing Professional Development courses.

Q3. What are the geospatial skills needs and gaps in your organisations, how can these be most effectively addressed, and how can careers in the sector be best promoted?

There is a shortage of, for example, homegrown GNSS and InSAR specialists in particular. These technologies should be promoted much more effectively through STEM ambassadors and careers events.

Q4. Are there any publicly or privately-held geospatial datasets that are currently challenging to access or use or of insufficient quality, but which you or your organisation would find valuable if these issues could be resolved? Please explain why this would be of value, and how access/quality could be improved?

Public procurement of novel datasets such as the UK relative land deformation map produced using the ISBAS processing technique from Geomatic Ventures Limited should be considered. Once established, underpinning of the ongoing updating of the dataset on for example a biennial basis, with managed access to UK public sector organisations, would be beneficial.

Q5: Do you anticipate that any changes will be needed to the both address data and the wider address ecosystem, to support emerging technologies? Please provide evidence of value to support any proposed changes.

We have no comment on this question.

Q6: How should the commission be looking to develop the UK's capability in Earth observation data, both technologically and to support an effective market?

Development of an integrated UK InSAR capability should be considered; we have several leading groups and at least three specialised companies but they operate individually and we do not realise their full potential.

Q7. Which new technologies should the commission focus on to provide new opportunities to process and exploit geospatial data for economic growth?

We need to turn to Artificial Intelligence and machine learning to handle the data volumes and provide rapid but accurate analyses in near real time.

There are big opportunities to apply geospatial technologies and generate growth in infrastructure, logistics and distribution networks, where such data are currently under exploited. These issues are of particular importance in the East Midlands, a distribution hub. Applications to, for example, new rail infrastructure such as HS2 are ripe to be developed. Other areas where this applies are agriculture and food production.

Q8. How can geospatial data and applications be used to support enhanced roll-out of future technologies?

One of the key future technologies is Artificial Intelligence. Geospatial data are the petrol in the engine of AI. Greater efforts should be made to connect the two.

Q9: What are the options for how public sector organisations could continue to invest in maintaining and enhancing our geospatial data assets?

Government should continue to follow the current free and open data policy and avoid charging for data wherever possible.

Q10: What areas of the underpinning geospatial infrastructure such as positioning technologies, including GPS and indoor positioning systems, and geodetic networks and frameworks to support them, should we be prioritising the development of, in order to support the emerging requirements for geospatial data?

Enhanced multi-GNSS and 5G enabled Network RTK infrastructure across the UK. A UK controlled and managed equivalent of the EU PRS system.

Q11: What role should the private sector have in both the development and maintenance of the underpinning infrastructure and enhancing the UK's geospatial data assets?

The private sector is well-placed to provide contributions to both infrastructure and data through public procurement contracts.

Q12. Do you face challenges when working with geospatial data from across the public sector? If so, what are they and how could value be better released? Are there any technical remedies or standards that could be adopted to improve the interoperability of geospatial data? Please provide supporting evidence of what these remedies could help to accomplish.

Not all major data sets are subject to the free and open data policy. Work should continue to bring as many national datasets as possible under its influence.

Q13. How can the Geospatial Commission act as a more effective customer for geospatial data on behalf of the public sector?

It can actively engage with and promote the use of the data arising from new UK technological breakthroughs such as the ISBAS InSAR processing method.

Q14. Are there any additional geospatial datasets, from the other partner bodies or other sources, that the public sector would derive significant benefit

from having access to, that might have novel and valuable use cases? What would that access look like?

Efforts should be made to secure access to UK 3D terrain data from a variety of public and private sources.

Q15: How can we best develop a single UK strategy, ensuring alignment between the individual strategies across the UK while still allowing for regional variations?

This requires a national conversation. Ensure that regional representatives are engaged in that process, from across the regional industrial, academic and public sector. Allow plenty of time for it to take place; it should not be rushed.

Q16: How can we best ensure effective local authority coordination and sharing of best practise, using location data to better deliver public services?

We have no comment on this question.

Q17: As a result of this analysis, we are prioritising the exploration of possible initiatives in the high-value categories identified:

- **property and land**
- **infrastructure and construction**
- **mobility**
- **natural resources**

- **sales and marketing**

What are the existing or potential geospatial applications which could be scaled-up or developed in order to capture economic value? (We would particularly welcome responses from industry and other bodies engaged in these sectors.)

InSAR ISBAS processing of satellite SAR data to extract ground motion over all land cover types, invented by the University of Nottingham and since developed and exploited through Geomatic Ventures Limited, is a real example of a cutting edge technology that could be leveraged and scaled up to provide new insights for property land, infrastructure, construction and natural resources monitoring.

Q18: Are there any other areas that we should look at as a priority?

Navigation and positioning in challenging areas: indoors, or in urban and rural settings, especially in relation to autonomous vehicles.

Applications in agriculture, forestry and urban planning.

Use of Earth Observation in policy & practice – we need to get it used more for environmental management applications and in direct support of major policies.

Finally, we need to grow its role in managing the subsurface. Decisions on the use of the ground beneath our get are ever more important and EO can play a role in improving them.

Q19: What are the main potential private and public sector innovations that will rely on the use of geospatial data to rollout, and are there corresponding regulatory challenges?

Where there are environmental risks identified and a lot of public scrutiny, the regulators should be encouraged through legislation to take full account of new technologies for identifying environmental factors. As an example, the ISBAS InSAR processing method is the only technology that provides actual values of land motion over all classes of land cover. This technology could be harnassed to monitor land motion caused by industries that have the potential to affect surface motion in the UK e.g. mining, onshore oil and gas, fracking, flood defences, large infrastructure projects and other installations (e.g. HS2, smart motorways & smart cities) etc.

Q20: How best can we make the UK's presence in the international geospatial world more visible?

Create an active programme for promoting international geospatial trade and inward investment. Encourage and incentivise geospatial champions from many different industries, academic institutions and the regions representing specific technological areas. Actively promote leading edge, emerging technologies that represent the best of British through the Geospatial Commision e.g. ISBAS InSAR processing.

Q21: Where should the UK be looking for points of comparison overseas? Who are the other international exemplars? What best practice is being modelled overseas that we can learn from?

Germany, Netherlands, Australia.

We should also watch closely what is done in the USA, although the conditions there are very different to those in the UK.

Thank you for your time in completing your response to our call for evidence.

Any questions, please get in touch with the Geospatial Commission via geospatialcommission@cabinetoffice.gov.uk

Geospatial Commission: Call For Evidence Response Questionnaire

Call for evidence - three key themes

We have identified three high-level themes that could help our approach to setting a strategy which are as follows:

1. **Supporting innovation in the geospatial sector**, exploring how to secure cutting edge skills, the right access to data, and opportunities from emerging technologies for the geospatial sector itself
2. **Enhancing the UK's geospatial assets,** looking at how best to align interests, avoid duplication, and instill best practice across the whole public sector
3. **Driving investment and productivity in geospatial applications**, asking in which wider sectors the most value lies from better exploitation and use of geospatial data, in the UK and internationally

Our questions

Q1. Is our view of the geospatial data types accurate? If not, what should be included or excluded from this?

In our opinion three data types would be sufficient, as the Geospatial Identifiers could be fit into Geospatial Data and Positional Data.

We think the type of real-time geospatial data is missing, e.g. traffic information, weather radar data, etc.

Q2. In addition to current government policy, what are the areas of geospatial skills where the commission could best focus, to help ensure the necessary capability within the UK for the future?

Assisting and providing support for start-ups in the geospatial sector to ensure UK companies can bring their ideas from the whiteboard to a functioning geospatial business model.

Q3. What are the geospatial skills needs and gaps in your organisations, how can these be most effectively addressed, and how can careers in the sector be best promoted?

Clean datasets can help in future to promote machine learning on those geospatial datasets, therefore knowledge of computer science is essential. Currently the geospatial data sector is lacking main stream data science skills having courses that promote combining main stream data science skills with geospatial skills would be benefitial.

Q4. Are there any publicly or privately-held geospatial datasets that are currently challenging to access or use or of insufficient quality, but which you or your organisation would find valuable if these issues could be resolved? Please explain why this would be of value, and how access/quality could be improved?

Hydrographic office's S-57 data would be benefitial, as well as any kind of elevation datasets from OS, UKHO, BGS, Crown Estate, licensing blocks datasets, BGS geochronological and resource datasets etc.

In lot of the cases, value value added services or products are created by by combining various datasets hence having easy access (if not open access) is crucial to building value added services and products.

Q5: Do you anticipate that any changes will be needed to the both address data and the wider address ecosystem, to support emerging technologies? Please provide evidence of value to support any proposed changes.

The coverage areas of postcodes could be refined (insurances screening, etc…)

Currently utilities, insurance, bank and other service providers use postcode to profile risk and availability of their services. A post code might cover quite large geographical area. As more granular data becomes commonplace, all those providers would be encouraged to provide further tailored products and it will also see more competitive offerings. Hence we believe further granularity is needed in address data system.

Q6: How should the commission be looking to develop the UK's capability in Earth observation data, both technologically and to support an effective market?

Try to keep affiliation with EU space agency to ensure full access to high quality earth observation data sets such Sentinel, Galileo, etc…

Q7. Which new technologies should the commission focus on to provide new opportunities to process and exploit geospatial data for economic growth?

Big data science and machine learning are key technologies which will benefit the growth of the geospatial economy significantly.

Q8. How can geospatial data and applications be used to support enhanced roll-out of future technologies?

As Internet of Things, Selfdriving cars, drones becomes common technologies in the near future they all will require detailed understaning of geospatial features. Hence it is important that the geospatial sector is prepared to support future technologies.

Q9: What are the options for how public sector organisations could continue to invest in maintaining and enhancing our geospatial data assets?

- Working with private organisations to develop derived data products from public sector datasets
- Free for development access to data held currently by government organisations
-

Q10: What areas of the underpinning geospatial infrastructure such as positioning technologies, including GPS and indoor positioning systems, and geodetic networks and frameworks to support them, should we be prioritising the development of, in order to support the emerging requirements for geospatial data?

Finer resolution satellite images than Sentinel datasets (up to 1m), free Lidar data,

Q11: What role should the private sector have in both the development and maintenance of the underpinning infrastructure and enhancing the UK's geospatial data assets?

Quite a significant role, otherwise key new developments will be missed and the provided datasets will be insufficient. Also the technological development have to keep up to date to prevent falling into a reactive role in the development of geospatial roles.

Q12. Do you face challenges when working with geospatial data from across the public sector? If so, what are they and how could value be better released? Are there any technical remedies or standards that could be adopted to improve the interoperability of geospatial data? Please provide supporting evidence of what these remedies could help to accomplish.

The largest improvement would be to standardize the way lat, longs are being published. If all lat longs could be displayed in decimal degrees that would make it much easier for all datasets to be implemented on the fly without the need of time intensive transformations.

Q13. How can the Geospatial Commission act as a more effective customer for geospatial data on behalf of the public sector?

--

Q14. Are there any additional geospatial datasets, from the other partner bodies or other sources, that the public sector would derive significant benefit

from having access to, that might have novel and valuable use cases? What would that access look like?

The following datasets would be benifitial to have full access to for the public to be able to develop more and innovative geospatial solutions:

-Crown Estate licensing blocks datasets
- BGS geochronological and resource datasets

Q15: How can we best develop a single UK strategy, ensuring alignment between the individual strategies across the UK while still allwoing for regional variations?

Establish proper channels for communication between geovernmentr bodies, academia and industry. Ideally set up a mixed advisory board having at least two meetings per year.

Q16: How can we best ensure effective local authority coordination and sharing of best practise, using location data to better deliver public services?

Inmproved communication and make sure laws are in place clarifying the proper use of geospatial data, which are clear and enables the most efficient and appropriate use of such data.

Q17: As a result of this analysis, we are prioritising the exploration of possible initiatives in the high-value categories identified:

- **property and land**
- **infrastructure and construction**
- **mobility**
- **natural resources**

- **sales and marketing**

What are the existing or potential geospatial applications which could be scaled-up or developed in order to capture economic value? (We would particularly welcome responses from industry and other bodies engaged in these sectors.)

The evoloving sector of proptech (property technology) needs to be scaled up and get supported by the provision of clean and sufficient data by the authorities. As part of the ongoing digitization and the use of machine learning the insights which can be gained by the use of geospatial data for proptech is limitless and will change the world we are acquiring property and land, as wel as in construction and natural resources. The provision of clean, standardized geospatial datasets are key in those sectors to generate unique and worl leading tools to asses these resources in a fast and efficient way.

Q18: Are there any other areas that we should look at as a priority?

Q19: What are the main potential private and public sector innovations that will rely on the use of geospatial data to rollout, and are there corresponding regulatory challenges?

See reoky in Q17. One regulatory challenge may be the use of address and telpohone information for individuals. Some limitations in privacy protection can hinder and slowdown some planned developments. In those field countries which do not have those regulations in place have a competitive advantage to the UK. Leaving the EU could give the UK more flexibility to adjust those laws, free from EU regulations and help to make the UK become more competitive in such areas.

Q20: How best can we make the UK's presence in the international geospatial world more visible?

Q21: Where should the UK be looking for points of comparison overseas? Who are the other international exemplars? What best practice is being modelled overseas that we can learn from?

See Q20.

Thank you for your time in completing your response to our call for evidence.

Call for evidence - three key themes

We have identified three high-level themes that could help our approach to setting a strategy which are as follows:

1. **Supporting innovation in the geospatial sector**, exploring how to secure cutting edge skills, the right access to data, and opportunities from emerging technologies for the geospatial sector itself
2. **Enhancing the UK's geospatial assets,** looking at how best to align interests, avoid duplication, and instill best practice across the whole public sector
3. **Driving investment and productivity in geospatial applications**, asking in which wider sectors the most value lies from better exploitation and use of geospatial data, in the UK and internationally

Our questions

Q1. Is our view of the geospatial data types accurate? If not, what should be included or excluded from this?

Generally, yes, however, we would also like to make the distinction between geospatial data that is in different 'states', recognising the value chain of data from raw data through to information in the form of data products and services. We believe that in the marine sector particularly, there is a complex picture of differing states of data, with much data available in its product state (e.g. navigational charts), which is not fit for other purposes, or in its raw state (e.g. individual hydrographic surveys), which requires significant value to be added prior to use.

Product-based data is designed and maintained for a particular purpose e.g. navigation and hence is unsuitable for wider use, being misleading with often associated safety and commercial risks. For example, navigational charts include only wrecks that are a danger to surface vessels, being around 20% of the known wrecks; for many non-navigational applications it is important to know about all wrecks. Considerable rework of navigational data is required to make it suitable for wider use including augmented navigational data with source data.

Raw or partially processed datasets may require significant expertise and effort in order to create products and services that are suitable to most end users. For example, OceanWise has processed many thousands of hydrographic survey datasets, including digitizing around 1000 paper survey sheets (known as fairsheets), comprising many billions of soundings to create a seamless Digital Elevation Model (DEM) of the UK Continental Shelf. The DEM is available at

different levels of resolution and is part of OceanWise's suite of marine mapping products and services that have been developed specifically for wider use e.g. in desktop and web GIS. A low-resolution version of the DEM is supplied to EMODnet, as part of the UK's commitment to create an Atlas of European Seas.

OceanWise marine mapping products and services are used widely across the public and private sectors in the U.K. and overseas. OceanWise has framework agreements with the Welsh, Scottish and Northern Irish Governments, and makes its data available to higher and further education via the Marine 'Digimap' service. The data is also used widely across the oil and gas, renewable energy, aquaculture, telecommunications and other sectors.

OceanWise personnel have been promoting wider and appropriate access to marine data for use in GIS and similar systems for over 20 years. Their efforts resulted in the first re-use licence agreement with the UK Hydrographic Office (UKHO) in 1998, the setting up of SeaZone Solutions Ltd as a wholly owned subsidiary of Admiralty Holdings Ltd. in 2005, and the establishment of OceanWise in 2010.

During this period, OceanWise personnel have championed marine mapping for wider purposes, rather than charting which is purely for navigation, for over 15 years, gaining much traction and bringing business back to the U.K. over this period. This success was aided by the creation of the Marine Spatial Data Infrastructure (MSDI) Working Group within the International Hydrographic Organisation (IHO) in 2006.

Made up primarily of national Hydrographic Office personnel, the MSDI Working Group has helped transform the way hydrographic offices now consider data. OceanWise continues to be an expert contributor to the working group, acts as its secretariat, and undertakes training on behalf of the IHO on this increasingly important topic.

Q2. In addition to current government policy, what are the areas of geospatial skills where the commission could best focus, to help ensure the necessary capability within the UK for the future?

There is a general focus across the sector on the use of GIS and similar technologies. There has been far less investment in the management and governance of data, leading to a lack of skills and understanding of this fundamental requirement. Geospatial data and its governance can be considered as data science, and as such should be a core requirement for anyone working in the geospatial sector. Sadly, this is often overlooked.

In recognition of the above, OceanWise is a member of the International Data Management Association (DAMA) and undertakes marine data management training via the International Hydrographic Organisation (IHO), as part of its capacity building programme, and directly to national Hydrographic Offices and Regional Hydrographic Commissions globally. OceanWise also collaborates with the Institute of Marine Science, Engineering and Technology (IMarEST) providing data management awareness training as open courses or to individual organisations. This training is backed up with ongoing advice and mentoring.

OceanWise is active in the Marine Environmental Data and Information Network (MEDIN) since its inception in 1999 (although the name has changed). Currently, OceanWise is MEDIN's only industrial sponsor, its personnel sit on MEDIN's Executive Team and working groups and represent MEDIN on certain working within government (e.g. the Marine Industries Liaison Group; MILG).

Q3. What are the geospatial skills needs and gaps in your organisations, how can these be most effectively addressed, and how can careers in the sector be best promoted?

In the marine sector, traditional GIS skills are less well developed than they are in terrestrial sectors. The marine sector, in terms of adoption and understanding of digital geospatial data (and GIS as a key enabler), is some years behind the terrestrial sector in the UK. This has hampered the development of digital adoption not only in the hydrographic sector, but also across U.K. ports and harbours and offshore sectors where paper-based work practices are still commonplace. In Government, divergence of career paths as a result of the introduction of Mapping and Charting grades in the Civil Service in the 1980's led to 'marine' seeing itself as different to 'terrestrial'.

We believe there is scope to streamline the number of individual government departments and agencies operating in the marine and coastal data domains (e.g. The Crown Estate, UK Meteorological Office, UK Hydrographic Office (UKHO), Defra, CEFAS, JNCC, MMO, Natural England, Historic England, MCA, BGS, Ordnance Survey). While the coordination of hydrographic survey work, for example, has improved in recent years, there is the potential to go much farther.

In particular, as well as with survey work, coordination should be extended to include the creation and maintenance of higher-level data products or services. Without this, products and service will be created multiple times in an ad hoc manner, incurring unnecessary expense and resulting in inconsistency.

Q4. Are there any publicly or privately-held geospatial datasets that are currently challenging to access or use or of insufficient quality, but which you or your organisation would find valuable if these issues could be resolved? Please explain why this would be of value, and how access/quality could be improved?

While more data is being made available under an Open Government Licence, which we consider a positive step forward, there is still much work to be done in respect of the structure and quality of this data.

There are numerous fundamental datasets where there is no authoritative 'ownership' body, despite the overlap in some areas of responsibility described in Q3. There are certain datasets where no organisation is able or willing to take on the responsibility for its effective management and curation; data and information obligations need to be clearly defined in public task.

This has been a topic of concern for the Marine Environmental Data and Information Network (MEDIN) for some time. As an example, the data register for Marine Spatial Planning identified 350+ datasets. Only a few of these datasets could be used immediately without significant rework or compromise. A typical example of a problematic marine data resource is submarine cables:

1) Historically the most comprehensive datasets were held by BT Marine and Cable & Wireless, but when these organisations were privatised, rather than the datasets being preserved and held as a national asset, the datasets were also transferred to the private sector. This historic dataset is now available in 'Geocable', a licensable software product, where the data is accessible only via the application.
2) The UK Hydrographic Office (UKHO) admits it is not the authority responsible for submarine cables, the Kingfisher Information Service (and associated industry bodies) are only interested in 'live' cables, and the leasing and licensing authorities (e.g. The Crown Estate and Marine Management Organisation (MMO)), who arguably should know what has been leased/licensed, state that it is not their remit either. It should be noted that UKHO takes cable data from various sources, including Geocable, that it then depicts on navigational charts. However, only cables of navigational significance are included. Recently, UKHO has been removing cables from charts that are in water depths greater than 20 metres (below Chart Datum), as they are not considered navigationally significant. Navigational charts are therefore not a definitive source of cable data fit for wider use, such as in marine spatial planning, as stated in our response to Q1.

With respect to source data generally, in the Geospatial Commission's consultation documents, the UKHO is promoted as being UK's marine geospatial data centre of excellence. In reality, it is more a centre for excellence for the production of navigational products and services. UKHO is responsible for very little of the data that it publishes, most data being sourced from other parts of government and the private sector e.g. ports, harbours, energy and telecoms companies.

The UK has no interoperable land-sea data despite numerous attempts to create

a seamless terrain model across the littoral zone. In 1991 the original Integrated Coastal Zone Map was produced by Ordnance Survey (OSGB) and UKHO. Sadly, whilst OSGB had the processes to handle digital data, the UKHO did not. The project was abandoned after just one paper sheet of Langstone Harbour was produced. A further project funded by HM Treasury under its 'Invest to Save' initiative in 2001 again fell by the wayside because the three agencies involved, OSGB, UKHO and BGS had, at that time, different governance models and priorities, and would not commit to developing the required terrain model.

In 2010, SeaZone Solutions Ltd. created marine mapping that was harmonised with land mapping from OSGB for six port cities, including London, for use by security services leading up to the 2012 Olympics. Sadly, after its initial success no sponsor in government could be found to maintain the harmonised dataset.

Presently, OceanWise has picked up this longstanding goal of creating marine mapping harmonised across the coastal zone, and has done this for three pilot areas, but ultimately this requires cooperation from OSGB to support the maintenance of the landside of these interoperable datasets.

Engagement with OSGB over many years has resulted in little progress, presumably because it has not been prioritised. Furthermore, as we have pointed out to OSGB, the coastal zone data in OSGB's datasets e.g. Terrain 5 and 50 are deficient in that the coastline is stepped between tiles (rather than being a continuous surface) and the marine area is populated by nonsensical values.

Q5: Do you anticipate that any changes will be needed to the both address data and the wider address ecosystem, to support emerging technologies? Please provide evidence of value to support any proposed changes.

A fundamental change is required to identify authorities which hold data as part of their public task, and therefore, should be responsible for maintaining the data as a national asset. We can provide numerous examples based on our experience preparing data registers for marine spatial planning for the MMO, for example.

Those core datasets can be published directly, or the custodian provided with the stimulus to make these datasets available to value added service providers, such as OceanWise, which are in a much better position to understand and react to user needs and market forces.

Q6: How should the commission be looking to develop the UK's capability in Earth observation data, both technologically and to support an effective market?

EO data is still considered novel and contentious by some marine data holders.

OceanWise considers the introduction of EO data in the marine as a useful option especially in defining coastal morphology and artefacts. Its usefulness in providing accurate water depths greater than 20-30 metres, even in clear water, remains limited. That said the market for this data has increased in the last five years mainly from scientists and planners.

The value of EO data to support oceanographic and hydrographic applications is not yet proven. UK Catapult is actively seeking new applications for EO data to assist the marine sector become more innovative and competitive.

OceanWise supports these initiatives but warns that on occasions public money has been used to create data products and services where there is already a successful company undertaking this role. We believe therefore that all public funded data related initiatives MUST include an impact assessment to include existing interested parties and markets, and potentially then allocate funding where it is more appropriate.

Q7. Which new technologies should the commission focus on to provide new opportunities to process and exploit geospatial data for economic growth?

In the marine sector, the increased deployment of autonomous underwater and autonomous surface vehicles (AUV/ASVs) will reduce the cost of data gathering. The National Oceanography Centre (NOC) should be commended on developing innovative platforms but appears to have missed the opportunity to develop commercial products from this initial success; the USA and Norway currently being the leading nations for commercial systems.

There is potential for greater industry involvement in marine monitoring programmes. This would facilitate private – public data sharing and help UK industry further develop expertise and systems with significant export potential. A lot has been achieved in this area but much more could be achieved with the right collaboration.

More generally, there is an emphasis on the platforms and sensors but less on data handling and the creation of end user products and services. OceanWise has attempted to raise this issue within UK Catapult, for example, but to date without success, presumably as it is not considered a priority for investment. We believe this is a mistake.

Q8. How can geospatial data and applications be used to support enhanced roll-out of future technologies?

Geospatial data underpins many different applications in so many ways, although this is often not recognised and certainly not at conceptual or design stages of many initiatives. The same can be said about data management generally.

OceanWise is actively involved in extending its marine mapping and environmental data sharing platform (aka marine IoT) to support such initiatives as 'Smart Ports', a key goal for Maritime 2050. This, and similar initiatives such as Smart Cities, will struggle or be less successful without the underpinning geospatial datasets and technologies to support them.

Q9: What are the options for how public sector organisations could continue to invest in maintaining and enhancing our geospatial data assets?

Geospatial data is never free, someone pays for it. Data made available by Google, for example, comes at a price i.e. Google's business model is to make geospatial data freely accessible as a hook to charge users through advertising or by exploiting their personal data (with their agreement). There needs to a wider and more insightful debate and how geospatial data is paid for, who pays for it, and to consider risks associated with relying on a purely public funding model.

Generally, we believe data acquired at public expense should be made accessible and the development of products and services based on these datasets should be left to the private sector. However, the capture, processing and publication of all data can - and arguably should - involve the private sector, which is more adept at being innovative and delivering value added data products and services to users.

The UK is in an excellent position to develop private – public sector partnerships to further exploit the capabilities of its leading geospatial data institutions and companies, as long as the institutions properly engage in this aim. There are too many people working in these institutions that see private enterprise as a bad thing, or as competition, rather than considering that if they worked with industry then everyone, especially UK plc, would be likely to benefit. Data sharing and working with industry should therefore be part of every applicable institution's public task.

As an example, OceanWise successfully works with UKHO to create products and services that it licenses to the private and public sector. The reduced licence fees paid by the public sector help fund the development, maintenance and support of these products and services, which are also licensed to the private sector at a higher price. A royalty is paid to UKHO for every data licence sold. Use of the data products and services by the public sector, and by further and higher education, provides credibility.

This model is now being exported by OceanWise to the benefit of OceanWise's stakeholders (i.e. its shareholders, employees, suppliers and local communities), and the UKHO and its stakeholders, and therefore UK plc.

UKHO effectively operates this model via its Admiralty branded navigational

products and services, which it understands and does well. In doing this, UKHO operates both as a private sector body (Admiralty Publishing Ltd. if you like) and as a national Hydrographic Office (i.e. data holder).

Q10: What areas of the underpinning geospatial infrastructure such as positioning technologies, including GPS and indoor positioning systems, and geodetic networks and frameworks to support them, should we be prioritising the development of, in order to support the emerging requirements for geospatial data?

The requirement for geodetic models to underpin positioning is vital. In the marine sector, the UKHO commissioned the UK and Ireland Vertical Offshore Reference Frame (VORF) a decade or so ago but the model was not made widely available to industry. This essential resource should be updated and made more accessible.

The recent data gathering programmes in the UK Overseas Territories (UKOTs) and commonwealth countries are designed to stimulate economic growth which could generate opportunities for UK business in the development of geospatial datasets, applications and services. One example is the Commonwealth Marine Economies (CME) Programme, which is delivering survey data to small island states in the Meso America and Caribbean region. Despite best efforts, engagement with private companies, by the responsible government agencies, has not been forthcoming thus opportunities to assist those small island states to date have been very limited.

Q11: What role should the private sector have in both the development and maintenance of the underpinning infrastructure and enhancing the UK's geospatial data assets?

As stated in Q1, OceanWise fulfils an essential role in providing marine mapping to the public and private sectors in the UK and farther afield, whilst the UKHO focuses on its core business of charting, which it does very well. It readily admits (at least to OceanWise in private) that UKHO does not possess the necessary skills and market understanding to fulfil such a role.

The work that OceanWise does involves taking source data where it exists, but primarily re-engineering source survey data and data captured from paper charts and making it suitable for use in desktop and web GIS e.g. as a seamless vector and gridded datasets UK Waters.

Looking ahead, the worst that could happen (and not only for OceanWise's business) is that UKHO makes its charted data available to non-navigational users without due regard to the fitness of purpose of these product-based datasets for use in wider applications, such as marine spatial planning.

OceanWise provides the UK input to EMODnet and our marine geospatial data products and services are gaining traction worldwide; we currently have contracts

in the Caribbean, Middle East and in South East Asia. Although OceanWise enjoys a good relationship with UKHO as a licensor, we have identified key areas where the management and supply of UKHO data could be improved and are in discussion with UKHO about this. Note that we also take source data from a number of international and national bodies e.g. the International Maritime Organisation (IMO) for which we pay a royalty for the use of the data.

Moreover, we believe that there are greater opportunities to be harnessed by OceanWise and UKHO collaborating to meet the emergent global demand for GIS related products and services for the benefit of UK plc.

Q12. Do you face challenges when working with geospatial data from across the public sector? If so, what are they and how could value be better released? Are there any technical remedies or standards that could be adopted to improve the interoperability of geospatial data? Please provide supporting evidence of what these remedies could help to accomplish.

A lack of authoritative source datasets as indicated in Q4 above. The quality of the datasets that are available. Competition from government itself by recreating products and services that are already in the market place and available at a lower cost, more so when personnel costs are taken into consideration.

OceanWise's vision is to create marine mapping that is harmonised with land mapping from, for example, Ordnance Survey (OSGB), an example output being an interoperable land-sea terrain model. Although OceanWise can proceed with the pilot dataset initiative alone, we would rather do this in collaboration with OSGB/OSNI as the interoperable datasets should be maintained either side of the assigned coastline.

Q13. How can the Geospatial Commission act as a more effective customer for geospatial data on behalf of the public sector?

Addressing the core issues e.g. authoritative datasets.
Stimulate a greater appetite for publically funded data to be shared and re-used
Public-private sector collaboration.

Trusting the private sector to deliver innovative products and services more cost effectively than Government thus benefitting UK users, and which would also stimulate business opportunities and growth overseas.

Presently, OceanWise has framework agreements with Scotland, Wales and Northern Ireland. We have promoted the benefits of a similar agreement within English and UK wide public bodies, but as yet these have failed to materialise. We continue to licence some of these bodies on an individual basis whilst recognising that collective are more cost effective for government.

Q14. Are there any additional geospatial datasets, from the other partner bodies or other sources, that the public sector would derive significant benefit from having access to, that might have novel and valuable use cases? What would that access look like?

Some organisations have been slow to update their policies and make data available as web services e.g. Historic England's wrecks database. Despite MEDIN funding, a successful pilot where the HE data was linked by OceanWise to its UKHO derived shipwrecks reference dataset is still not made available.

Q15: How can we best ensure effective local authority coordination and sharing of best practise, using location data to better deliver public services?

A public sector marine mapping agreement (PSMMA), so that central and local government is using the same consistent base map, ideally harmonised across the coastal zone with terrestrial data.

Q16: As a result of this analysis, we are prioritising the exploration of possible initiatives in the high-value categories identified:

- **property and land**
- **infrastructure and construction**
- **mobility**
- **natural resources**
- **sales and marketing**

What are the existing or potential geospatial applications which could be scaled-up or developed in order to capture economic value? (We would particularly welcome responses from industry and other bodies engaged in these sectors.)

As stated above, whilst marine may not be a priority this may not matter, as OceanWise and UKHO already enjoy a healthy relationship, and only minor adjustments are required in order to maximise the benefits from this relationship. Ideally this would be done in collaboration with other agencies, e.g. OSGB with regard to interoperable land-sea geospatial data, and BGS. Such collaboration would not only benefit UK public sector but boost overseas export potential.

Q17: Are there any other areas that we should look at as a priority?

None that are not included in our response to other questions.

Q18: What are the main potential private and public sector innovations that will rely on the use of geospatial data to rollout, and are there corresponding regulatory challenges?

Application based products and services. Situational awareness, risk management, foundational datasets for big data type initiatives e.g. Blue Marine Foundation's Big Marine Data Project involving OceanWise and the RNLI.

OceanWise provides GIS and related services to ports and harbours. There is scope to streamline ports' compliance responsibilities with those of the public sector.

Q19: How best can we make the UK's presence in the international geospatial world more visible?

Collaboration and cooperation between the private and public sectors, especially where UK Government already has a foothold e.g. Cefas in Kuwait; UKHO in South West Pacific and UKHO/NOC in the Caribbean. OceanWise is also active in these areas and better collaboration would enhance the likelihood of greater success.

Q20: Where should the UK be looking for points of comparison overseas? Who are the other international exemplars? What best practice is being modelled overseas that we can learn from?

The UK leads this field in the private (e.g. OceanWise) and public (e.g. UK Hydrographic Office) sector. What is missing is greater collaboration to realise the greater potential that this could deliver.

As stated above, OceanWise helped establish and is a major contributor to the IHO Marine SDI Working Group, having delivered training courses and mentoring to countries on this topic for almost 10 years. We have seen considerable uptake of national SDI, and the engagement of national marine bodies, especially in South East Asia over this period. UK is struggling to grasp the opportunities to be harnessed by a greater public-private partnership approach to overseas programmes and projects.

Thank you for your time in completing your response to our call for evidence.

Any questions, please get in touch with the Geospatial Commission via geospatialcommission@cabinetoffice.gov.uk

OGC's Response to the Geospatial Commission's "Call For Evidence"

Please submit your completed questionnaire to:
geospatialcommission@cabinetoffice.gov.uk.

About you and your organisation

Name	[Text redacted]
Organisation	Open Geospatial Consortium
Job title	[Text redacted]
Address	[Text redacted]
E-mail	[Text redacted]

Other - please state **X**	**International non-profit standards development organisation**

A preface to the OGC response to the call for evidence

The Open Geospatial Consortium (OGC) is a not-for-profit voluntary consensus standards organisation with over 520 members and a worldwide presence. The OGC membership in the United Kingdom is the third highest number of members in any nation and has many other international industry organisations with a local presence. Since the the “call for evidence” was announced we have held two face to face meetings in London with members as well as an online webinar and engaged with a variety of our alliance partners including the AGI, RICS, buildingSMART and others to assist in developing this response.

Whilst this response will focus on the relevance of the open geospatial standards that are developed in the consortium we have added where appropriate information and comments provided from throughout the membership and also references to activities we are aware of through our alliance partners.

About the OGC

Of our 520 strong global membership approximately 40% are commercial service providers, systems integrators, and technology providers. The members range from small and medium-sized enterprises to large multinational organisations in the public, private, academic, and not-for-profit sectors. The Consortium was established in 1994 and offers a wealth of historical records, reports and presentation materials relating to geospatial problem-solving. Our goal is to define and deliver the industry standards platform for location interoperability across the web, wireless, and mainstream Information and Communications Technology (ICT). The OGC is the only industry consortium that comprehensively addresses issues related to location and space to enable the integration of all spatial data types and real-time spatially related technologies, including but not limited to the enterprise, cloud, mobile, and sensor environments.

OGC processes and standards facilitate a common depiction of information for multiple organisations which have varying perspectives on the spatial nature of content that need to be merged. OGC's value derives from the fact that spatial information is pervasive in human activity and only a well-run, global, consensus standards process can provide the environment to make location information ubiquitous in mainstream information processing. OGC members collaboratively define and develop the interoperability architecture needed to solve simple to significantly complex problems that involve the integration of dissimilar computing models important to a wide variety of communities. The development and use of open standards do not require members to give up intellectual property or trade secrets.

The use of open standards to connect components, applications, and content allows a “white box” view on the components' functionality and interfaces without revealing implementation details. This fulfils both the industry requirement for protection of intellectual property and the user requirement for transparency. OGC members

collaboratively define and develop the interoperability architecture needed to address simple to significantly complex applications that involve the integration of dissimilar computing models important to diverse communities of interest. With over 70 working groups, the spectrum of OGC's work currently covers a broad and expanding range of domains and technology areas.

OGC manages four main programs:

• Standards Program - The OGC community works in a formal consensus process to arrive at approved (or "adopted") OGC® standards http://www.opengeospatial.org/docs/is

• Innovation Program - The OGC Innovation Program (IP) is an essential part of OGC's fast, effective, inclusive user-driven process to develop, evolve, test, demonstrate, and promote OGC Standards. Over the past 16 years, OGC's Innovation Program has conducted over 100 initiatives designed to accelerate the development of emerging concepts and drive global trends in interoperability. http://www.opengeospatial.org/ogc/programs/ip

• Compliance and Certification - The purpose of the program is to increase system interoperability while reducing technology risks. Vendors gain confidence that they are providing a compliant product, whereas buyers gain confidence that a compliant product will work with another compliant product based on the same OGC standard. http://www.opengeospatial.org/compliance An important component of achieving interoperability in solutions is to ask for compliant software. There is an OGC Guide to Software acquisition that provides advice on how to achieve this https://portal.opengeospatial.org/files/15-002r5

• Outreach and Communication - The permanent success of any standards effort depends on users consistently choosing products based on those standards. The purpose of this program is to lead outreach and education, nurture strategic partnerships and alliances, and develop and support regional and sector programs.

OGC operates on both a virtual and in-person basis, with quarterly meetings scheduled each year in North America, Europe and Asia.

What are Open Standards and why are the important ?

In 2014 OGC, the International Standards Organisation committee TC211 and the International Hydrographic Organisation jointly presented a Guide to the Role of Geospatial Standards to the United Nations Global Geospatial Information Management committee. The Committee endorsed the guide and its companion document as recommended international best practice. Both the current versions of the guide and its companion document can be found at the following links:

- http://ggim.un.org/meetings/GGIM-committee/8th-Session/documents/Standards_Guide_2018.pdf

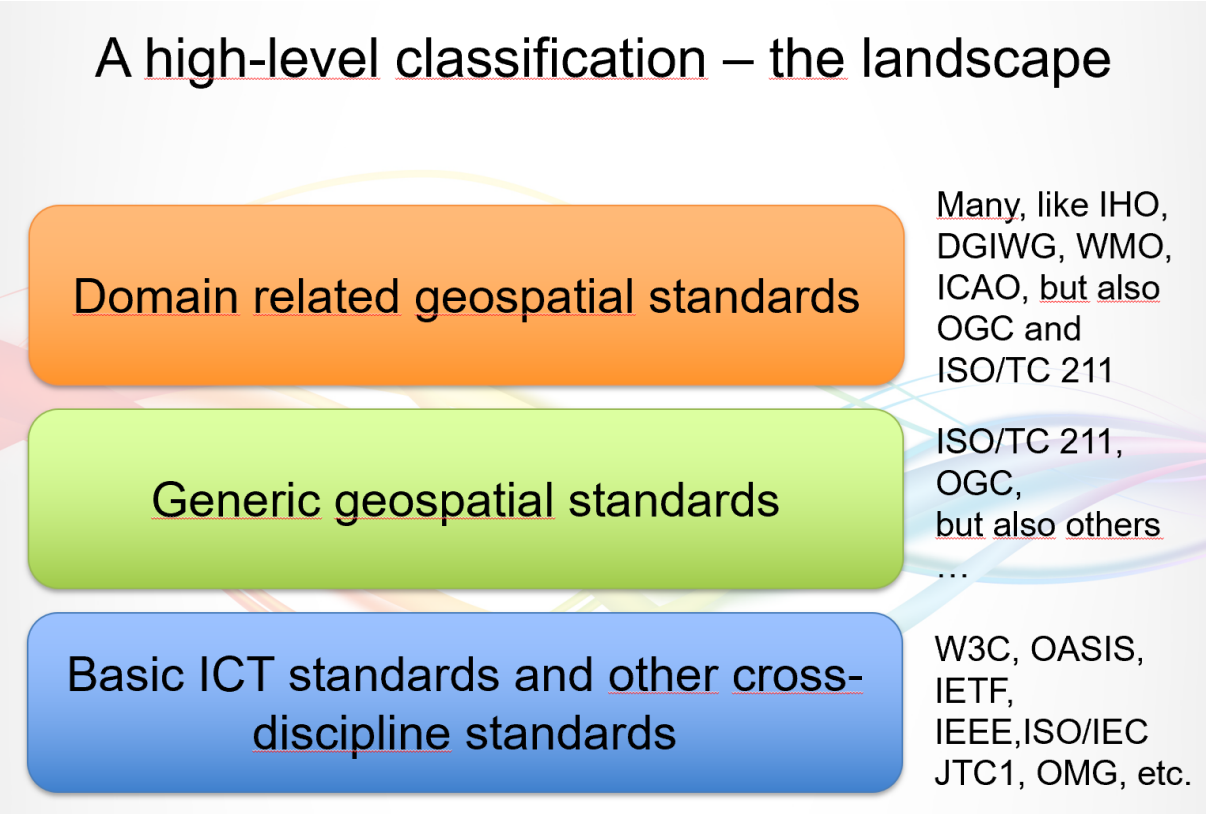
- http://ggim.un.org/meetings/GGIM-committee/8th-Session/documents/Standards-by-Tier-2018.pdf

These documents state that the goal of open standards it to achieve interoperability and to do that an open standard must be:

- Publicly available;
- Unencumbered by patents and other intellectual property;
- Anyone can download and use the standard (nondiscriminatory);
- No license fees;
- Vendor neutral;
- Data neutral;
- Agreed to in a consensus decision making process;
- No single entity controls the standard

"Different governments and enterprises may choose to use geospatial information and software applications which do not rely on open standards. The most immediate drawback of such an approach is that the organization has created an information and technology silo that presents users with many hidden challenges such as delays and costs of expanding or adapting data and software tools to work with other resources, software or organizations. In an ever changing world, open standards help assure that organizations can more quickly take advantage of new geospatial information sources and new technology tools. Open standards are a central element in the growing trend to open government"[1]

[1] Guide to the Role of Geospatial Standards http://ggim.un.org/meetings/GGIM-committee/8th-Session/documents/Standards_Guide_2018.pdf



The world of technical standards can be a complicated one to understand and is very much a land of acronyms. However, it is important to realise that the standards development organisations (SDOs) all play an important role and focus on particular domains and technical areas and are reliant on

working with each other to ensure we can enjoy a globally connected world of data sharing and access. The diagram above illustrates the 3 primary layers of standards that our geospatial community relies on and the column to the right indicates the various SDOs who are involved in that layer.

To help understand this landscape better the UN-GGIM in collaboration with the OGC, ISO/TC211 and IHO undertook to match existing standards to those global issue areas that have been identified by the committee.

	UN-GGIM issue	Number of standards		
		ISO	OGC	IHO
(a)	Developing a national, regional and global strategic framework for geospatial information	6	5	1
(b)	Establishing institutional arrangements and legal and common frameworks	5	2	7
(c)	Building capability and capacity, especially in developing countries	5	2	2
(d)	Assuring the quality of geospatial information	7	6	8
(e)	Promoting data sharing, accessibility and dissemination	63	24	15
(f)	Embracing trends in information technology	20	18	3
(g)	Promoting geospatial advocacy and awareness	-	4	2
(h)	Working in partnership with civil society and the private sector	-	-	-
(i)	Linking geospatial information to statistics	7	6	-

OGC in the United Kingdom

There are over 30 member organisations in the United Kingdom

1Spatial Group Ltd.
Beare, Matthew
cadcorp (Computer Aided Development Corp.) Ltd.
Defence Geospatial Information Working Group (DGIWG)
Defence Science & Technology Laboratories (Dstl)
DEFRA
Envitia Ltd.
Esri UK
European Centre for Medium-Range Weather Forecasts (ECMWF)
Frazer-Nash Consultancy Ltd
GE Smallworld
Helyx secure information systems ltd
HR Wallingford
International Association of Oil & Gas Producers (IOGP)
Natural Environment Research Council (NERC)
Office for National Statistics
Ordnance Survey
OSCRE International Ltd.
Polar View Earth Observation Limited
Royal Institution of Chartered Surveyors (RICS)
Satellite Applications Catapult
Science & Technology Facilities Council (STFC)
Scottish Government
UK Met Office
United Kingdom Hydrographic Office
University College London
University of Manchester
University of Nottingham
University of Reading
University of Southampton
whitehead, brandon

These members represent all tiers of government, small companies, large corporations, research institutes and universities. The UK also has the first ever European based Strategic member being Ordnance Survey. As well as organisations who are based in the UK a number of international member organisations have a presence here these include IBM, Google, Hexagon, ESRI, Oracle and many others.

In order to discuss and share regional knowledge there is a UK & Ireland Forum. This is currently chaired by Andrew Hughes of the British Geological Survey and meets between 3 - 4 times per year. This forum has built a partnership with both the Association for Geographic Information (AGI) and their standards committee IST36 (British Standards Institute) to help maximise the development of appropriate standards and supporting material to achieve interoperability in the UK.

On a final note, it is important to highlight that the INSPIRE framework is underpinned by many OGC standards in particular the webservice standards and it is encouraging to hear that the UK intends to continue following this framework for geospatial interoperabilty for the foreseeable future despite the political changes in the relationship between the EU and the UK.

Call for evidence - three key themes

We have identified three high-level themes that could help our approach to setting a strategy which are as follows:

1. **Supporting innovation in the geospatial sector**, exploring how to secure cutting edge skills, the right access to data, and opportunities from emerging technologies for the geospatial sector itself
2. **Enhancing the UK's geospatial assets,** looking at how best to align interests, avoid duplication, and instill best practice across the whole public sector
3. **Driving investment and productivity in geospatial applications**, asking in which wider sectors the most value lies from better exploitation and use of geospatial data, in the UK and internationally

Q1. Is our view of the geospatial data types accurate? If not, what should be included or excluded from this?

One of the great challenges for the geospatial community and those outside it is agreeing on terminology. The list as defined is fine, but we would encourage the use of the term “geospatial resources” rather than types as the overall description of the list. This avoids the situation where type 1 is called ‘geospatial data’ and is also a type of ‘geospatial data’. Having an agreed definition that is then consistently used is important for helping everyone to understand. It should be noted that some members indicated that it is important to define the distinction between data and information.

Q2. In addition to current government policy, what are the areas of geospatial skills where the commission could best focus, to help ensure the necessary capability within the UK for the future?

Best practice in terms of use of standards and metadata should be encouraged as early as possible within the educational system. For example, geospatial standards should be mandated in the Secondary School or University curriculum. Further at degree level the understanding of interoperability should be introduced. Good examples of this can be found in curriculums at both University of Nottingham courses and University of Southampton, but broader and more consistent coursework not just in GIS/Geospatial courses is key. Understanding concepts of geospatial and the importance of interoperability for geospatial data is important to those studying Computer Science, Environmental Sciences, Engineering and even Health. All these disciplines would benefit from earlier exposure to some basic understanding of the complexities of geospatial data and the importance of the standards that relate to it. Concepts and practice such as geospatial analytics, particularly in a Big Data context should also be taught or at least introduced. Additionally, System-of-Systems engineering, particularly in the context of a UK-wide Sensor Web/IoT that is underpinned by standards-based technologies should be developed.

Q3. What are the geospatial skills needs and gaps in your organisations, how can these be most effectively addressed, and how can careers in the sector be best promoted?

Whilst the OGC supports geospatial professionals in achieving interoperability, organisations such as AGI (www.agi.org.uk) and Royal Geographical Society (RGS) are best placed to respond to the issues related to skills needs within the UK context. These are valued alliance partners of the OGC and we support their position on skills

and gaps in UK-based organisations and are encouraged by their proposal to conduct a study in the geospatial skills gap.

Q4. Are there any publicly or privately-held geospatial datasets that are currently challenging to access or use or of insufficient quality, but which you or your organisation would find valuable if these issues could be resolved? Please explain why this would be of value, and how access/quality could be improved?

The UK has made great strides in making their public sector data more available, e.g. data.gov.uk. However general sentiment among members is that this portal is not as well set up to handle geospatial data as it could be. Further metadata is not well policed which makes finding data more difficult than it should be. It is suggested that the data itself and even good metadata catalogues should not be moved, but the interconnectedness of catalogues should be observed, i.e. Single source of truth. It's not as well curated as it could be. One suggestion provided was that the way forward could be to re-organise data.gov.uk to focus on the challenges of the UK in a thematic way. The case study themes outlined in Question 12 may provide a starting point for this. And in order to achieve single source of truth, organisations should be encouraged to take an open standards approach and provide data through webservices and APIs. Ensuring data is available and accessible for each of the cast study areas will be critical to addressing the challenges in each.

Q5: Do you anticipate that any changes will be needed to the both address data and the wider address ecosystem, to support emerging technologies? Please provide evidence of value to support any proposed changes.

Addresses are one type of administrative data and addressing globally is created and managed in a variety of ways. As OGC Board Member Ed Parsons of Google is quoted to say "If you can't link to it does it exist?[2] The world is moving towards this idea of "linked data" and future address data will need to consider how it will connect to this new linked world. Key standards in this space will be the Discrete Global Grid Systems (DGGS) http://www.opengeospatial.org/projects/groups/dggsswg and Spatial Data on the Web Best Practice https://www.w3.org/TR/sdw-bp/

Obviously the main addressing system of the UK is the Post Office's post code system. This should be preserved, but mapped to an international standards and made openly available to maximise its use.

[2] Ed Parsons https://www.edparsons.com/2017/09/cant-link-exist/

Q6: How should the commission be looking to develop the UK's capability in Earth observation data, both technologically and to support an effective market?

Members would encourage the UK to develop Sovereign satellite systems, while continuing to participate in ESA if possible. Further the UK should look to collaborate more with NASA and build collaboration with other national EO systems and Space Agencies e.g. new Australian Space Agency, China and others. Consideration should be given as to how to exploit existing data and use EO assets. Alongside this the GC should improve national connectivity between EO responsible bodies/orgs eg. UK Space Agency, etc.

To drive up the level of innovation for the use of EO data then the GC should encourage agencies to provide data in the easiest and best way possible. One potential solution is datacubes – important for not only research but enabling access to EO time series data for use by SMEs in a size that they can use. The OpenDataCube project is a global community in support of developing this technology and includes the Satellite Applications Catapult in the UK https://www.opendatacube.org/projects

Q7. Which new technologies should the commission focus on to provide new opportunities to process and exploit geospatial data for economic growth?

There are a number of reports that have examined this issue which the GC are encouraged to digest.

These include but are not limited to:

OGC Technology Trends
- www.opengeospatial.org/OGCTechTrends

UNGGIM 5 – 10 year trends
- www.ggim.un.org/knowledgebase/KnowledgebaseArticle50444.aspx

AGI Foresight Report
- www.agi.org.uk/news/foresight-report

Location Based Marketing Association: 2018 Global Location Trends Report
- www.thelbma.com

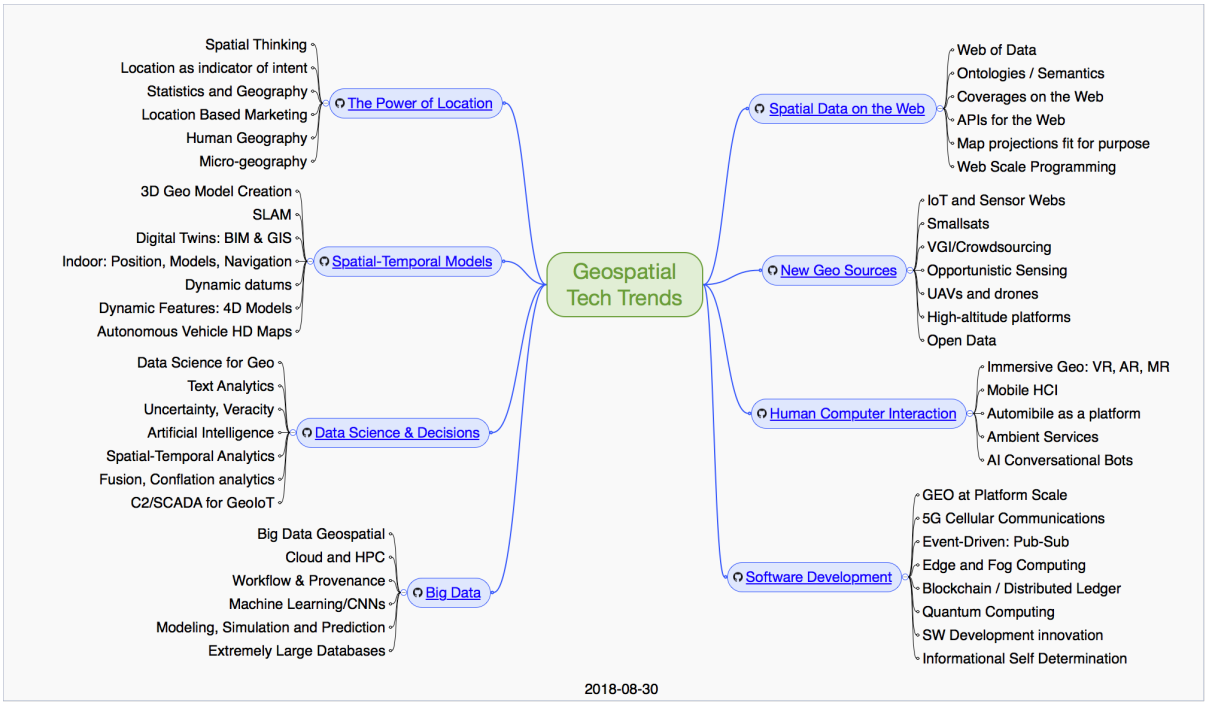


Figure from the OGC Technology Trends as at August 2018

It should be noted however that technology is a tool and it is more important to focus on the problems that need to be solved and how emerging technology can help to solve them.

Q8. How can geospatial data and applications be used to support enhanced roll-out of future technologies?

Ensure that the geospatial data and applications support open geospatial standards. This allows innovators to focus on the problems they are trying to solve and not on re-inventing the wheel. The INSPIRE framework (www.inspire.ec.europa.eu) is one that can underpin this work.

Q9: What are the options for how public sector organisations could continue to invest in maintaining and enhancing our geospatial data assets?

Ensure that appropriate cost recovery is in place or appropriate central funding to ensure not only maintenance of core National geospatial data assets, but funding that enables the evolution of these assets as technology changes and needs of users change. Eg. OS Mastermap. Additionally, focus on the value-added services that public sector organisations can offer such as derived products, consultancy and analytics.

Q10: What areas of the underpinning geospatial infrastructure such as positioning technologies, including GPS and indoor positioning systems, and geodetic networks and frameworks to support them, should we be prioritising the development of, in order to support the emerging requirements for geospatial data?

Ensuring an open standards compliant approach across all technology capturing or sharing location data will ensure an effective infrastructure that operates well together and accepts playing with new friends. We would see standards as a critical piece the UK's geospatial infrastructure.

A priority should be how reusable or multi use infrastructure is such Smart City technologies underpinned by Sensor Webs. For example, having a variety of sensors on streetlights could help people manage their health better (i.e. air quality). It could also help people prepare respond to floods and other natural disaster (saving local economies a lot of money). They could also be used to assist logistics companies in tracking vehicles or support Law Enforcement.

Q11: What role should the private sector have in both the development and maintenance of the underpinning infrastructure and enhancing the UK's geospatial data assets?

UK geospatial data assets should provide a platform on which the private sector can offer its analytical and value-added services. For example, it should be possible for marketing information referenced to UK geospatial data assets to be augmented with statistical data/demographics readily. A user should be able to review a UK Govt catalogue of all of the other information that they could reference to each UK Govt geospatial data asset. Further use should be made of international initiatives such as the UNGGIM Guide to the Role of Geospatial Standards and also the work on Fundamental Data http://ggim.un.org/UNGGIM-wg9/

Q12. Do you face challenges when working with geospatial data from across the public sector? If so, what are they and how could value be better released? Are there any technical remedies or standards that could be adopted to improve the interoperability of geospatial data? Please provide supporting evidence of what these remedies could help to accomplish.

In terms of specific standards it is important to highlight the outputs of the report from the IST36 UK Geospatial Standards for the UK. https://www.agi.org.uk/about/resources/category/80-standards-group?download=343:standards-committee-minutes-21-sep-2018

In this report the key UK geospatial data agencies shared which geospatial standards they used. Encouragingly a number of these were the same. Below is an excerpt from the report:

Emerging consensus

A number of standards were mentioned by quite a few presenters, and therefore represent an existing consensus at least in some areas. Most of these are standards encouraged by the European Commission's INSPIRE initiative, for metadata, map views, feature access, and feature data. The INSPIRE specifications for various themes were also mentioned.

Data access standards

The consensus on the day was in the area of data access – perhaps reflecting that open standards are most apparent at organisations' external interfaces. • OGC Web Map Service (WMS; ISO 19128; INSPIRE) – seven organisations • OGC Web Feature Service (WFS; ISO 19142; INSPIRE) – five organisations • GeoJSON / IETF RFC 7946 within its capabilities – five organisations • OGC Geography Markup Language (GML; ISO 19136; INSPIRE) – four organisations Emerging (three organisations each): • working with REST architectural patterns. • forms of JSON other than GeoJSON • XML other than GML • CSV, including 'CSV for the web'

Metadata for discovery, evaluation, and use Most organisations publish their metadata using ISO 19115 / 19119 / 19139, as advised by INSPIRE, and use the UK GEMINI profile & guidance. This is the structure and format used by data.gov.uk, as well as by some off the shelf solutions.

Gazetteers The UK's own standard, BS7666 Spatial datasets for geographical referencing, which underpins Local & National Address Gazetteers was mentioned by four organisations.

We would encourage the GC to use the information gathered in this report to build supporting policy and strategy on the use of geospatial standards throughout the UK.

CASE STUDIES

The responses to this question were many and varied. To try and capture the essence of the member input we have described case studies that members see as the current key challenges that face the UK and how improved geospatial data access would assist.

Britain is an established industrial nation and its housing and infrastructure is based on significant construction around 150 years ago. For example, London's sewers were built in 1860s (en.wikipedia.org/wiki/Joseph_Bazalgette) and designed for a population of two million against a current one of 8.6m. If the UK is to cope with rising urban populations, climate change as well as competing in an increasingly globalised

marketplace then the next few decades need to be increasingly digital. Cities have to become resilient and sustainable as well as smart to respond to these challenges. The following illustrates the individual components or use cases based on contributions from OGC members and which are required to be met to enable these challenges to be addressed.

The use cases:

Civil Society – The aim of the GC is economic growth but should include well-being and its associated data. There is a linkage between physical processes and their data and well-being. For example atmospheric pollution is currently linked to increased deaths from respiratory disease; behaviour change and accessibility in terms of place should be considered. Alongside this, the Office of Civil Society within DCMS has put out a well-being strategy (see https://www.gov.uk/government/publications/civil-society-strategy-building-a-future-that-works-for-everyone) which should be taken into account along with the UN's Sustainable Development Goals or SDG.

Water - This is obviously important for sustaining human life, but too much results in floods and too little causes droughts. Already there are various APIs exposing data for river flows and groundwater levels (www.shoothill.com/Floods&Rivers) as well as trial ones for rainfall (environment.data.gov.uk/flood-monitoring/doc/rainfall). However the picture is not complete by any means and examples such as the NZ adoption of WaterML should be investigated (https://www.oecd.org/environment/resources/New-Zealand-water-quality-data-case-study-information-system-diffuse-pollution.pdf).

Underground - If the infrastructure required for increasing urbanisation and the officiant transport of goods and people is to be achieved then the use of the underground is key. Further to enable the best use of urban areas (e.g. Singapore) is to be made. However, underground space is not regulated (or is fragmented at best, e.g. mineral rights). If we are to enable the efficient use of this space then an understanding of what is "down there" is required. Data needs to be made open and to be shared using common standards. One example of this is KLIP in northern Europe where data can be exchanged on infrastructure projects (www.klip.be) and the OGC is promoting this process via its UG CDS and subsequent pilot (see www.opengeospatial.org/projects/initiatives/ugipilot).

Natural hazards - Than natural world is still a threat to human beings and their activities, even in the UK: landslides, floods, earthquakes and impacts of hazards from overseas origin such as Volcanic ash and tsunamis can affect the UK. Short term – "disasters" and longer term built environment and their effect on safe operation, e.g. nuclear power stations. Data on the historic occurrence and the processes that lead to these hazards need to be made available. This will enable those tasked with dealing with these hazards or their consequences is required. The approach has been adopted by the Natural Hazard Partnership, which is an example of cross-

governmental working for environmental prediction within the UK (see www.naturalhazardspartnership.org.uk).

Met Office 3D/4D - It is self-evident that weather knows no national boundaries. Met Office outputs need to be consumed by a number of different organisations both onshore in the UK and offshore. The Met Community and the Met Office produce very large datasets with significant geographical coverage. All these data need to be shared with the relevant customer either other WMOs or users such as aviation, air quality providers, 1st responders and so on. The OGC standard NetCDF underpins the exchange of data (see www.opengeospatial.org/standards/netcdf).

Model/Sim - Putting numbers on things is extremely important to be able to assess what impact any change may have. Modelling and simulation covers quantification of processes as well as 3D simulation of events or gaming. Process models are proliferating along with the data they consume and produce. Some way of exchanging these data either once the models have run or whilst they are running is important. The Simulation Interoperability Standards Organisation (SISO) & OGC have recently signed a MoU and as this is complemented by the OGC standard OpenMI for linking models at runtime (www.opengeospatial.org/standards/openmi).

Public safety - Data are collected about what we do and how we move around our environment. These data can and should be protected, but the sharing of it with the appropriate authorities need to be considered. For example in emergency situations such as fire or terrorist incident. Consideration should be given to data sharing during routine events with large amounts of people, e.g. FA Cup Final and emergency situations such as a 9/11 type incident (see www.bloomberg.com/news/features/2017-08-10/nobody-knows-what-lies-beneath-new-york-city).

Urban Environment - As the world's population continues to urbanise, the available space for citizens to live safe and productive lives is under pressure. How do we find better ways to understand and use the space available in our urban communities while taking into account diverse and varied populations and landscapes? The capacity to collect and share high quality Location data is at the heart of understanding how we live, work and play in our urban environments and is key to helping us see the pathways to improving the lives of citizens. Topics such as transport, public safety, resilience and sustainability, building modelling, underground infrastructure, sensors and the IoT and the ever increasing world of big data and analytics all have relevance. Other related initiatives are the Integrated Digital Built Environment - a joint initiative of the OGC and buildingSMART international looking at how we bring into reality concepts, such as the Digital Twin, for our cities.

Further information:

Integrated Digital Built Environment: http://www.opengeospatial.org/projects/groups/idbesc

buildingSMART International: https://www.buildingsmart.org/

RICS: https://www.rics.org/uk/

UK BIM Alliance: http://www.ukbimalliance.org/

Unmanned Autonomous Vehicles / Connected Autonomous Vehicles - A key component of the UK Industrial Strategy focuses on the need for a national infrastructure capable of supporting a nationwide network of CAVs. Location data will be critical in the development of this infrastructure. As well as those vehicles on the ground the increased use of drones for both public and commercial purpose means an ever greater demand for geospatial data but importantly the ability to share that data to all the users who need it. This might be law enforcement, the public, the drone owner or the customer.

Key examples here are:

- the startup company Flock https://flockcover.com/
- Ordnance Survey's e-CAV project https://www.ordnancesurvey.co.uk/about/news/2018/ecave-project-uk-driverless-vehicle-infrastructure.html

Agriculture - With the UN predicting that 68% of the world's population will be living in an urban environment by 2050[3] the stress and challenge of not only producing enough food to feed the growing population, but having the resources to farm and produce that food are also increasing. Advances in technology provide many opportunities for the agricultural sector from use of EO, to sensors, autonomous equipment and high precision farming. However much of the data need is still not available to farmers, or is too difficult for them to use well. This could be soils data, water, climate, disease spread, etc. This will be a key challenge for every nation in the world, but for the UK with a very large population and comparatively small population, maximising use and improving efficiencies will be vital.

Further information regarding interoperability in the Agriculture sector can be found the Location Powers: Agriculture Summit held in New Zealand in 2017 http://www.locationpowers.net/events/1712newzealand/index.php

Marine - It was noted that the Marine sector did not seem very represented across this questionnaire and yet many challenges face the UK that are marine related. For example Smart Ports and how cargo is brought into a port and then moved through an urban environment/corridor to multiple location on land and the effect of Coastal erosion. Moving into the future it is important to consider how we will merge both

[3] https://www.un.org/development/desa/en/news/population/2018-revision-of-world-urbanization-prospects.html

marine and terrestrial models so that we can understand the implications of planning decisions, commercial trade movement and environmental change between the land and the sea. In the standards world an important partnership between OGC & IHO has been develop to begin looking at some of the technical interoperability challenge in this space http://www.opengeospatial.org/projects/groups/marinedwg

Location Based Consumer Services - Much of the discussion thus far has focused somewhat on what we would describe as "traditional" geospatial areas. However to realise the estimated £11 billion in unlocked value the geospatial industry needs to reach out and connect with organisation in the commercial market space who are becoming more and more reliant on geospatial. The Location Based Marketing Association www.thelbma.com has members who are supermarket chains, global fast food organisations and telecommunications companies. The broad array of case studies https://thelbma.com/case-studies/ that have been gathered from this membership shows the amazing value that these commercial companies derive from using location data. However, there is still a divide between this innovative marketing world and our traditional geospatial community. If the GC could bridge a gap between the two there would be many benefits of collaboration. For example - if a company deploying indoor sensors for marketing purposes inside shops could also use the same sensors to connect to public safety services, both could benefit.

Integration of Geospatial and Statistics - The statistical domain is evolving to move from the traditional capture of data through surveys such as census, to a more dynamic integration of data from across a wide range of domains that can make statistics more timely, more accurate, and better understood.
Geospatial information is a key data source in transforming the way that statistics are produced as it has the potential to fit into every component of the Generic Statistical Business Process Model.

The complexity of bringing together survey, administrative, and big data with geospatial information and earth observation is driving an increased need for standardisation to support better statistical outputs. OGC has recently worked with members and the UN-GGIM Integration of Geospatial and Statistics Working Group to charter a new domain working group to look at the challenges. A few of the specific challenges under consideration within the proposed DWG include:

- Data integration – how can semantic web technology be used to improve the integration of geospatial and statistical datasets?
- Data Capture – how can geospatial data be used to include the capture and georeferencing of survey, administrative and big datasets used in the production of statistics?
- Data processing – as geospatial objects do not fit within traditional database structures these are currently handled externally to the rest of the statistical process through dedicated geospatial systems.
- Data exchange – given the lack of interoperability between statistical and geospatial data architectures, frameworks, metadata and standards, how can data be shared through a service orientated approach?
- Data analysis – a lack of comparability between geographic datasets at a national, regional, continental and global level makes international analysis

difficult.

- Knowledge – there is a lack of understanding within the statistical community of the geospatial tools and standards that can support the statistical system, and a corresponding situation with the geospatial community.

Q13. How can the Geospatial Commission act as a more effective customer for geospatial data on behalf of the public sector?

Firstly they should ensure that the quality of the data is not comprised by public release of the data. Funding should be made available to maintain and update datasets that are truly open and freely available. Secondly the GC should act as a broker/quality assurance/enabler to ensure that data from the public sector can be made available with good metadata in a usable format.

Q14. Are there any additional geospatial datasets, from the other partner bodies or other sources, that the public sector would derive significant benefit from having access to, that might have novel and valuable use cases? What would that access look like?

Based on OGC member discussion our recommended priorities for datasets to release should be:

1. Underground utilities data. New display methods are emerging (e.g. AR displays) that could help to deliver underground utilities data to telecoms engineers and city engineers in more effective ways.
2. Post Office postcode data (this might be difficult because the Post Office is now a limited company) or a suitably similar dataset
3. Sensor networks - enabling the release of these to be used by public bodies or private industry.

Please see answers to Q12 for a range of suitable use cases, including use of underground space and smart ports / transport networks.

Q15: How can we best develop a single UK strategy, ensuring alignment between the individual strategies across the UK while still allowing for regional variations?

We would suggest that the GC exploits the many and various existing networks both UK and globally. They should operate a twin-track approach of working through and knowledge sharing:

Working through – AGI, OGC UK & Ireland Forum, RICS, UK BIM Alliance, to have topic/challenge based discussion and workshops

Knowledge Sharing – participate in and learn from the forums around the world that consider Geospatial data

They should collect requirements/visions from all regions around the globe. By harmonising those requirements, they can develop a Core/Foundation strategy that covers the key aspects that are important to all regions. Then provide the regions a framework for extending the Core/Foundation strategy by developing sub-strategies. Veto any aspects in the sub-strategy that contradict the principles of the Core/Foundation strategy.

Q16: How can we best ensure effective local authority coordination and sharing of best practise, using location data to better deliver public services?

Require local authorities to engage and participate in organisations such as AGI, OGC and others. These organisations offer several platforms for knowledge exchange.

Q17: As a result of this analysis, we are prioritising the exploration of possible initiatives in the high-value categories identified:

- **property and land**
- **infrastructure and construction**
- **mobility**
- **natural resources**
- **sales and marketing**

What are the existing or potential geospatial applications which could be scaled-up or developed in order to capture economic value? (We would particularly welcome responses from industry and other bodies engaged in these sectors.)

A list of use cases is provided in response to Q12, however the ones specifically that relate to this question are:

1. Connected and autonomous vehicles
2. Unmanned aerial vehicles (UAVs)
3. Use of underground space / subsurface
4. Smart ports and coastal processes / erosion in the context connected cities

Q18: Are there any other areas that we should look at as a priority?

Data and services to facilitate the development and use of underground space should be a priority. It is the key to unlocking cities and ensuring they are resilient and sustainable into the middle of the 21st century.

As well as this, there should be recognition of the role that research organisations play to stimulate and develop innovation that can be commercialised – An international example of a Public/Private/Research Partnership would be FrontierSI in Australia (formerly the CRC – Spatial Information) https://frontiersi.com.au/

Q19: What are the main potential private and public sector innovations that will rely on the use of geospatial data to rollout, and are there corresponding regulatory challenges?

- Connected and autonomous vehicles
- e-Health
- Unmanned Traffic Management (in airspace mixed with UAVs and Passenger Aircraft)
- Sensor Web and Internet of Things (IoT)

Q20: How best can we make the UK's presence in the international geospatial world more visible?

UK organisations should have more involvement in international organisations such as the OGC and UNGGIM. Alongside this, creating improved connection between UK agencies to as to provide a more "joined up" international offering, we have a lot to offer but it would be better with collaborative and joint agency approaches. Eg. UKHO, MO, OS, BGS, etc.

However, recognising the UK is in a strong position with both public and private sector organisations and their use of geospatial data then the GC should facilitate mentoring / Knowledge Sharing with countries of lower income, ie. DAC countries (http://www.oecd.org/dac/financing-sustainable-development/development-finance-standards/DAC_List_ODA_Recipients2014to2017_flows_En.pdf). This will spread UK's expertise and influence, but also test our approach in more demanding environments.

Q21: Where should the UK be looking for points of comparison overseas? Who are the other international exemplars? What best practice is being modelled overseas that we can learn from?

There are many exemplars that we could offer here. Two important regional examples to mention are:

INSPIRE https://inspire.ec.europa.eu/ Much has already been referenced to INSPIRE. However it is important to recognise that much of the data sharing and access we enjoy across the European region is thanks to this framework and the standards that underpin it.

ArcticSDI https://arctic-sdi.org/ The ArcticSDI is at present one of the best examples of data sharing in that is is federated network of national SDIs facilitated by open standards. This holds high the principle of "single source of truth".

At a national scale the ones highlighted below focus on particular exemplars within each continent:

North America

The United States is a good model to learn from. Their Spatial Data Infrastructure (SDI) was established by a Presidential Directive Executive Order 12096 in the Clinton Administration. Since then every US President has reaffirmed their commitment to SDI. Most recently through the signing of the Geospatial Data Act (https://www.congress.gov/bill/115th-congress/house-bill/3522) The work of the Federal Geographic Data Committee https://www.fgdc.gov/ is regarded highly throughout the world and the impact of the National Information Exchange Model https://www.niem.gov/ has greatly improved geospatial data sharing through the country. In Canada of note is the Spatial Data Infrastructure https://www.nrcan.gc.ca/earth-sciences/geomatics/canadas-spatial-data-infrastructure/10783. Mexico's INEGI has also pioneered the combination of GEO/STATs in one organisation.

Australasia

Australia has a number of excellent initiatives including GeoScience Australia's Digital Earth Australia work on Datacube, Discrete Global Grid System, Dynamic Datums and the long standing partnership between states and federal government through the Public Sector Mapping Agency as well as organisations such as CSIRO and FrontierSI which are world-leading in terms of open standards. As mentioned above, New Zealand has championed the use of WaterML to create seamless data transfer within the water environment and was one of the pioneers in publishing their open geospatial data in Geopackage format (as has the Australian Bureau of Statistics this year)

http://www.ga.gov.au/dea/odc
https://www.linz.govt.nz/
https://frontiersi.com.au/

Asia

Given its size and limited land mass, Singapore has space issues to deal with and is one of the world leaders in the use of CityGML and has been pushing the development of Underground city models in collaboration with the UK & New York. In India there is a focus on Smart Cities and involvement in Plugfests whereas Japan has a focus on transport.

Europe

In The Netherlands Geonovum is an exemplar as how a country handles geostandards and innovation, for other countries KLIP used to coordinate the use of the sub-surface for shallow infrastructure. France the geospatial community is integrated with Government activity eg. Interoperability Days. Whilst Germany has very strong 3D City Modelling eg. use for Solar Panel investigation, and urban planning

Africa

Tanzania - for use of both crowd sourced data in evidence based decision making, aerial drones for survey and exposing the aerial data via OGC WMS for use globally.

Lastly we would mention the developments in the Defence Community.and the end of the Cold War has seen a switch to different roles for the UK's Armed Forces with peacekeeping, assisting in natural disasters, preventing terrorism coming to the fore. This has meant greater links to the civil society eg. DSTL working closely with OS to fund important interoperability activity in the OGC tested eg. WMT links to looking at use of MapBox box tiles format and how to achieve greater interoperability.

To complete our response we would like to acknowledge and thank all our contributors:

Call for evidence - three key themes

We have identified three high-level themes that could help our approach to setting a strategy which are as follows:

1. **Supporting innovation in the geospatial sector**, exploring how to secure cutting edge skills, the right access to data, and opportunities from emerging technologies for the geospatial sector itself
2. **Enhancing the UK's geospatial assets,** looking at how best to align interests, avoid duplication, and instill best practice across the whole public sector
3. **Driving investment and productivity in geospatial applications**, asking in which wider sectors the most value lies from better exploitation and use of geospatial data, in the UK and internationally

Our questions

Q1. Is our view of the geospatial data types accurate? If not, what should be included or excluded from this?

Geospatial data should be thought about as an extra attribute that describes the 'where'. While this can take many forms (co-ordinates, place name, etc) it is related to a location. Therefore for 1 and 2 are the same thing. Geospatial identifiers (3) are just data too (i.e. a list of places with their coordinates).

Geospatial services are not data. This should be in its own segment with technology and applications.

Q2. In addition to current government policy, what are the areas of geospatial skills where the commission could best focus, to help ensure the necessary capability within the UK for the future?

The biggest gap in government has been enabling access to software and hardware to enable spatial data to be exploited. In my experience Government Digital Service and CO haven't been able to provide the support I've required in my roles at MoD, DECC, BEIS or OGA.

Skills within government are often limited to small pockets in individual Central Government Departments, Local Authorities and Agencies. Many organisations pull in experts for projects rather than maintaining and building skills internally or from a Government talent pool.

There needs to be better appreciation of geospatial technologies for non geospatial specialists, especially at management levels. Driving effective use of geospatial technology is often difficult for this reason.

Q3. What are the geospatial skills needs and gaps in your organisations, how can these be most effectively addressed, and how can careers in the sector be best promoted?

The Oil and Gas Authority is part of a wider industry that has been a the forefront of spatial data and technologies since the 1960s. Careers in this sector require geospatial skills along with other Geoscientific and IT skills.
As a GovCo we struggle to attract and retain talent. This can only be addressed by raising the profile of geospatial/Geography/GIS to be a primary profession alongside being a geologist, economist, etc.
Geospatial professions also need to be recognised as specialist professions that require either a specific education or specific experience to acquire skills that cannot otherwise be 'picked up'.
In recruitment drives, the OGA has relatively few people that can write computer code and use ETL software, skills which will be key for cleaning data and applying future technology.

Q4. Are there any publicly or privately-held geospatial datasets that are currently challenging to access or use or of insufficient quality, but which you or your organisation would find valuable if these issues could be resolved? Please explain why this would be of value, and how access/quality could be improved?

Although improving access is a key goal for UK geospatial data, alignment of similar data and alignment on means of sharing are prerequisites for this goal.

The Oil and Gas authority pulls in information from multiple Government departments including BEIS, TCE, UKHO, National Grid and others. These all vary in quality (as do our own datasets), however there is no central repository or single source of the truth for many datasets vital to the UK. Examples:

- Offshore infrastructure (Wind farms, Platforms, cables, pipelines)
- Onshore infrastructure (Pipelines (Oil, Gas or Water))

The OGA have passed legislation to enable this data to be collected in the future if held by relevant persons involved in Oil and Gas Activities.

Identifying the needs of various organisations is vital in understand what datasets need to be captured.

Q5: Do you anticipate that any changes will be needed to the both address data and the wider address ecosystem, to support emerging technologies? Please provide evidence of value to support any proposed changes.

Yes. We don't make best use of current technologies. The majority of Government and public bodies are trapped in legacy systems, which are increasingly difficult to maintain and ultimately move away from.
It is common to see organistions trapped on legacy systems and unable to take advantage of SaaS options and new platforms.

Q6: How should the commission be looking to develop the UK's capability in Earth observation data, both technologically and to support an effective market?

No comments

Q7. Which new technologies should the commission focus on to provide new opportunities to process and exploit geospatial data for economic growth?

Enabling access to MS Azure, AWS and others along with the raft of spatial applications that can utilise this computing power (ESRI, R, MS services and Amazon Services).
That will then need to be followed by data management expertise.

Q8. How can geospatial data and applications be used to support enhanced roll-out of future technologies?

They will showcase the power of that technology and enable further investment in the data that underpins it. It will hopefully result in geospatial data and applications being seen as the new normal.
This is comparable to Uber, Google maps, etc. All underpinned by location, however a surprisingly low number of people realise that.

Clean geospatial data will be essential if to be consumed by future technologies. Geospatial applications and adding geospatial information to data can highlight and in some cases automatically correct incorrect data.

Q9: What are the options for how public sector organisations could continue to invest in maintaining and enhancing our geospatial data assets?

This is difficult as the government isn't always the owner of this data. Therefore collecting, maintaining and enchancing data has to achieved through effective reglations and/or through Governments business as usual.
The link between the need for data and using it to make better decisions within government process needs to be made clearer. This will pave the way for effective regulation to be drafted that will mandate data owners to report to government.
It also needs to be recognised that, although we have some world-class datasets, we also have a lot of datasets which fall far below those standards. The time and resources required to improve them and the return on investment needs to be more widely understood.

Q10: What areas of the underpinning geospatial infrastructure such as positioning technologies, including GPS and indoor positioning systems, and geodetic networks and frameworks to support them, should we be prioritising

the development of, in order to support the emerging requirements for geospatial data?

These technologies are driven by private sector use cases and economic factors. While I think there is room for the UK government to encourage inward investment in these areas I don't believe it to to the role of the Geospatial Commission.
I think the foundational geospatial work will enable growth in these areas.

Q11: What role should the private sector have in both the development and maintenance of the underpinning infrastructure and enhancing the UK's geospatial data assets?

Significant. Partnering with organisations such Microsoft, AWS, ESRI, etc would enable the UK to benefit from the worldwide experience these organisations have.

Q12. Do you face challenges when working with geospatial data from across the public sector? If so, what are they and how could value be better released? Are there any technical remedies or standards that could be adopted to improve the interoperability of geospatial data? Please provide supporting evidence of what these remedies could help to accomplish.

Legacy file download systems are common place across the public sector and cost significant time when attempting to keep them up to date on internal systems. Changes to methods of publishing or structure of datasets, though sometimes unavoidable, happens too often and causes further time to investigate changes.

In some cases, it is possible, even with legacy file download systems, to automate updates to datasets on internal systems at considerable time-cost. For others, however, automation isn't even possible.

The OGA publish data that can be consumed in multiple formats, all formats, API (machine to machine) services, and web displays of the data come from a single

source. API services are streaming the most current data live.
Areas of government that have enabled API web services and where this has occurred it has generated an industry in application development. This industry develops and adds significant value to the datasets for end users.

Example of the OGA doing this - https://www.esriuk.com/content/dam/distributor-restricted/esriuk-com/news/thinkgis/ThinkGIS-Issue45.pdf

Q13. How can the Geospatial Commission act as a more effective customer for geospatial data on behalf of the public sector?

No comments

Q14. Are there any additional geospatial datasets, from the other partner bodies or other sources, that the public sector would derive significant benefit from having access to, that might have novel and valuable use cases? What would that access look like?

No comments

Q15: How can we best develop a single UK strategy, ensuring alignment between the individual strategies across the UK while still allwoing for regional variations?

This is a difficult question and various attempts have been made by government to create a single strategy. These have had mixed successes. A key driver needs to be Government Science and Engineering Geography profession, which professionalises geography with a wide user group.

Variations to a strategy not only need to be regional, but account for the differences in multi industries all with differing user needs. What will underpin that is the skills in geospatial technologies, applications and data management as well as the investment spatial thinking at policy/strategy level.

Q16: How can we best ensure effective local authority coordination and sharing of best practise, using location data to better deliver public services?

Consistency and standards across local government. In reality is difficult without prescribing what IT, software, people, etc a local authority should use.
Another option would be to centralise the delivery of services underpinned by geospatial data.

Q17: As a result of this analysis, we are prioritising the exploration of possible initiatives in the high-value categories identified:

- **property and land**
- **infrastructure and construction**
- **mobility**
- **natural resources**
- **sales and marketing**

What are the existing or potential geospatial applications which could be scaled-up or developed in order to capture economic value? (We would particularly welcome responses from industry and other bodies engaged in these sectors.)

UK Oil and Gas National Data Repository (NDR) - https://www.ogauthority.co.uk/news-publications/news/2018/the-uk-s-first-oil-and-gas-national-data-repository-to-deliver-additional-value-and-inward-investment-to-the-uk/

OGA's Data Centre - https://data-ogauthority.opendata.arcgis.com/ & https://www.ogauthority.co.uk/data-centre/

The latter moved off gov.uk in October 2016 as it didn't support our requirements

or user needs.

Q18: Are there any other areas that we should look at as a priority?

No comments

Q19: What are the main potential private and public sector innovations that will rely on the use of geospatial data to rollout, and are there corresponding regulatory challenges?

No comments

Q20: How best can we make the UK's presence in the international geospatial world more visible?

It would require the UK to lead some exemplar projects and talk about these at various industry/vendor events around the world. We (UK Government) are already world leaders in some areas and many UK nationals present at events around the world.

Q21: Where should the UK be looking for points of comparison overseas? Who are the other international exemplars? What best practice is being modelled overseas that we can learn from?

The National Geosptial Intelligence Agency (USA) – Part of the US DoD. Responsible for supplying geospatial data and services to the US armed forces. Smart Dubai (UAE) – Excellent example of bring BIM and GIS together with public facing information.

Thank you for your time in completing your response to our call for evidence.

Any questions, please get in touch with the Geospatial Commission via geospatialcommission@cabinetoffice.gov.uk

Call for evidence - three key themes

We have identified three high-level themes that could help our approach to setting a strategy which are as follows:

1. **Supporting innovation in the geospatial sector**, exploring how to secure cutting edge skills, the right access to data, and opportunities from emerging technologies for the geospatial sector itself
2. **Enhancing the UK's geospatial assets,** looking at how best to align interests, avoid duplication, and instill best practice across the whole public sector

3. **Driving investment and productivity in geospatial applications**, asking in which wider sectors the most value lies from better exploitation and use of geospatial data, in the UK and internationally

Our questions

Q1. Is our view of the geospatial data types accurate? If not, what should be included or excluded from this?

1. We recommend that the Commission recognises that geospatial data is infrastructure and adopts the view of geospatial data infrastructure described in this response.
2. Geospatial data infrastructure[1] consists of five components, all of them important:
    a. **data assets**, such as identifiers, registers and datasets;
    b. the **standards and technologies** used to curate and provide access to those data assets;
    c. the **guidance and policies** that inform the use and management of data assets and the data infrastructure itself;
    d. the **organisations** that govern the data infrastructure;
    e. the **communities** involved in contributing to or maintaining it, and those who are impacted by decisions that are made using it.
3. Within geospatial data infrastructure are three types of data assets: identifiers, registers and datasets.
    a. **Identifiers** are crucial to the process of sharing information. Geospatial identifiers provide unambiguous labels or reference numbers for the things described in a geospatial dataset, such as lamp-posts, roads, houses, or administrative areas. They are fundamentally important in being able to make connections between data, which puts them at the heart of how we create value from structured data.[2] The UK's core geospatial identifiers include: TOID (TOpographic IDentifier); UPRN (Unique Property Reference Number); UARN (Unique Address Reference Number); Office for National Statistics (ONS) codes for administrative areas; USRN (Universal Street Reference Number), Land Registry Title Number; and Land Registry INSPIRE ID.
    b. **Registers** are lists of reference data that help to improve the consistency and quality in how data is published. They help to build confidence and trust in data by clarifying where different data stewards are referring to the same things in the same way. Registers are typically maintained by a custodian who defines the scope and contents of the list. The work of maintaining a list is often collaborative[3] requiring input from multiple organisations. Examples of registers for geospatial data in the UK include:

[1] https://theodi.org/topic/data-infrastructure/
[2] https://theodi.org/article/white-paper-enhancing-open-data-with-identifiers/
[3] https://theodi.org/article/registers-and-collaboration-making-lists-we-can-trust-report/

the Foreign and Commonwealth Office's country register[4] which provides a list of countries recognised by the UK; the Land Registry's official register of land titles, which will include the identifier and reference data for each title; lists of locations such as National Rail's list of railway stations[5]; and the EPSG Geodetic Parameter Dataset[6], which provides reference data about different coordinate reference systems.

c. **Geospatial datasets** underpin our understanding of the natural and man-made landscape around us and how we interact with it. They include data on land cover, height, geology, habitats, water resources, geographic and political boundaries, structures, addresses, utilities and transport networks.

4. We do not think it makes sense to consider "Geospatial services" as a geospatial data type. Products and services require access to geospatial data assets (identifiers, registers and datasets), as well as consideration of other aspects of geospatial data infrastructure such as guidance and policies. A strong geospatial data infrastructure supports an ecosystem of intermediaries and data users that create value-added geospatial services as well as derived datasets and products.
5. Geospatial data exists on a spectrum from closed, to shared to open[7]. Like other parts of data infrastructure, it should be as open as possible while respecting privacy, national security and commercial confidentiality. This is even more important for geospatial data infrastructure because it is a foundation for other parts of our national data infrastructure: restrictions on use of geospatial data can limit the use and utility of other data too.

Q2. In addition to current government policy, what are the areas of geospatial skills where the commission could best focus, to help ensure the necessary capability within the UK for the future?

1. We think that everyone must have the opportunity to understand how data can be, and is being, used. In the context of the geospatial sector, the Commission should consider capability - data literacy and understanding, data science skills and the ability to use and share data to help solve problems - as an important area or theme.
2. The UK should be equipped with the skills in Artificial Intelligence and Machine Learning to take advantage of the increasing amounts of available geospatial datasets - including earth observation data and point clouds - to support the development of geospatial products and services. The Commission must recognise that not everyone needs the same geospatial skills and that there are

4 https://country.register.gov.uk/
5 http://www.nationalrail.co.uk/stations_destinations/48541.aspx
6 http://www.epsg-registry.org/
7 https://theodi.org/about-the-odi/the-data-spectrum/

different paths to expertise. The ODI's data skills framework is a useful tool for exploring this topic[8].

3. In addition to these skills, to realise the full benefits of geospatial data to the UK's economy and society, public sector policymakers and service designers, business leaders, startups and community groups need to have a basic understanding of the importance of geospatial data and how it can be used better to achieve their goals. These should include understanding how to navigate privacy issues that may arise when using geospatial data, and approaches for sharing geospatial data while protecting privacy. For example, this might include how and when to normalise or validate address data you collect so that the data is more shareable with other organisations, or how to ensure that Google Maps or OpenStreetMap (OSM) displays the location of a business accurately so that customers are more likely to discover it.

Q3. What are the geospatial skills needs and gaps in your organisations, how can these be most effectively addressed, and how can careers in the sector be best promoted?

1. No response to this question.

Q4. Are there any publicly or privately-held geospatial datasets that are currently challenging to access or use or of insufficient quality, but which you or your organisation would find valuable if these issues could be resolved? Please explain why this would be of value, and how access/quality could be improved?

[8] https://theodi.org/article/open-data-skills-framework/

1. Geospatial data infrastructure helps people, communities and organisations make decisions in almost all aspects of life and across all sectors of our economy. Limits on its openness - including who can access geospatial data assets - creates significant friction that reduces the benefits we stand to gain from it. In her foreword to the 2008 UK location strategy[9], [Text redacted] described that "in almost everything, people need to know when and where things happen: place matters." The UK must make geospatial data infrastructure as open as possible to maximise its value.
2. The Commission should prioritise increasing access to identifiers to help improve the quality, consistency and interoperability of geospatial and other data assets. It should work with both private, public and third sector data stewards to make identifiers available as open data that anyone can access, use and share[10]. A 2014 ODI and Thomson Reuters report[11] highlights the importance of open identifiers to make connections between datasets. Open identifiers are free from licensing or IP restrictions that might restrict how the identifiers can be used, including to publish derived data. The basic reference data associated with the identifiers should also be made available under an open licence. The report also highlights the need for data stewards to be transparent about how they assign and manage identifiers, and for the provision of a basic set of services that will support reuse of the identifiers (e.g. to help link together data assets from different organisations). At present, some of the key identifiers that underpin the UK's geospatial data infrastructure and that are not yet open are: TOIDs, UPRNs, UDPRNs and UMRRNs stewarded by Royal Mail; UARNs stewarded by the Valuation Office Agency; USRNs stewarded by GeoPlace; and Land Registry Title Numbers and Land Registry INSPIRE IDs. Two important identifiers, UPRNs[12] and TOIDs[13], both have some Intellectual Property (IP) and licensing restrictions which limit their reuse. For example, TOIDs can only be republished by Ordnance Survey (OS) customers[14]. The OS have over the last few years,[15] been permitting customers and licensees of their products to publish datasets that include UPRNs, although the licensing remains complex[16]. The UK has many competing[17] and overlapping identifiers for addresses, property and land which adds complexity to the publication and reuse of data. It is often not clear how

10 https://theodi.org/article/what-is-open-data-and-why-should-we-care/
11 https://innovation.thomsonreuters.com/en/labs/data-identifiers.html
12 https://www.ordnancesurvey.co.uk/about/governance/policies/addressbase-uprn.html
13 https://www.ordnancesurvey.co.uk/about/governance/policies/os-mastermap-toids.html
14 https://www.ordnancesurvey.co.uk/about/governance/policies/os-mastermap-toids.html
15 https://www.ordnancesurvey.co.uk/about/news/2015/uprn-release-sharing-location-data.html
16 https://blog.ldodds.com/2015/09/02/how-and-when-can-uprns-can-be-a-part-of-open-data/
17 https://www.owenboswarva.com/blog/post-addr2.htm

identifiers are assigned, how they relate to each other. Lack of reference data, including on boundaries, makes it hard to understand how they align with one another. The identifiers are also typically only published as part of larger datasets. For example, TOIDs and the basic reference data associated with them are only available as part of MasterMap products. This limits their potential uses.

3. The Commission should prioritise increasing access to geospatial data assets that are frequently used to validate or augment other datasets. Current barriers or restrictions to their use ripple through to other datasets, products and services. Two significant data assets of this type that the Commission should focus on are:
    a. Address data. We describe in detail how access could be improved and why this would be of value in our response to Question 5.
    b. The current work to increase access to OS MasterMap[18] is a step forward in strengthening the UK's geospatial infrastructure, but there's a lot more to do. In general, this will let users who only need small amounts of data to access it for free, on demand; it does not help those who need larger volumes or who want flexibility in what they do with the derived data they create. The current activities will create some new freemium models but these must continued to be revisited. They must be seen as a step on a journey to an OS Mastermap which is as open as possible, while protecting national security. Being clear that this is the direction of travel will allow both the OS and data stakeholders to develop appropriate business models.
    c. As the Commission opens up these datasets it must engage with public sector organisations that use them to create derived data, for example the Land Registry or local authorities, to ensure that associated licencing restrictions are removed from those derived datasets.
4. The Commission should prioritise increasing access to other geospatial data assets based on ongoing engagement with, and understanding of the needs of, data users. This is particularly important in the context of:
    a. supporting emerging technologies - including driverless cars, drones and artificial intelligence - which are likely to require access to specific types of high quality and timely geospatial data and geospatial data infrastructure. Supporting these technologies with access to geospatial data will reduce barriers to business growth and support UK Government investments made through the Industrial Strategy Grand Challenges.
    b. supporting other policy initiatives such as improving access to democracy, housing and planning, or the creation of a beneficial ownership register[19].
5. The rapidly growing innovation in geospatial technology and increasing competition amongst providers of geospatial data means that some of our public sector data stewards will need to adopt new and innovative business models.

[18] https://www.ordnancesurvey.co.uk/business-and-government/products/open-mastermap.html

[19] https://democracyclub.org.uk/ https://mhclgdigital.blog.gov.uk/category/digital-land-services/ https://researchbriefings.parliament.uk/ResearchBriefing/Summary/CBP-8259

The Commission should also prioritise data assets that help public sector organisations explore new business or revenue generation models, such as freemium APIs or quality guarantees. We discuss this further in our response to Question 9.

Q5: Do you anticipate that any changes will be needed to the both address data and the wider address ecosystem, to support emerging technologies? Please provide evidence of value to support any proposed changes.

1. Addresses are part of our everyday lives: they pinpoint where we live and work and connect us to local services we rely on. The Commission should make a register of address data available under an open licence for anyone to access, use and share.
2. UK Government already controls the rights for most UK address data through the OS and Geoplace. In 2015, the ODI ran a project to explore whether it was possible to recreate the UK's address list. We established that, principally due to the legal uncertainty over who holds intellectual property rights in many current sets of address data, it was not possible and that UK Government would have to intervene to make this data available. The final report contains the evidence of value available at the time[20].
3. Subsequently, UK Government started a new £5m project to explore creating an address register. We would recommend that the Commission release the findings of that project to help the wider ecosystem understand the challenges it discovered and where new evidence might be required[21].
4. The Commission should also explore ways in which the UK's address system will need to adapt to changing user needs and expectations. Emerging technologies, such as Connected and Autonomous Vehicles (CAVs) and drones, may require access to sustainable, high quality address data in new ways - for example, the such as data related to landing paths for drone delivery services. The rise of 'floating transport', such as dockless bicycle hire schemes, and alternative delivery locations, such as parcel collection boxes and delivery to car boot, is likely to result in a broader change in the way we consider addresses. This may mean adopting location systems such as Pluscodes[22], in which case we strongly recommended the adoption of open standards to increase adoption and avoid lock-in.

[20] https://theodi.org/project/creating-the-uks-first-free-and-open-address-list/
[21] https://www.gov.uk/government/speeches/geoplace-conference-matt-hancock-speech
[22] https://plus.codes/

Q6: How should the commission be looking to develop the UK's capability in Earth observation data, both technologically and to support an effective market?

1. The Commission should ensure that Earth Observation (EO) data collected and maintained by public sector organisations is made as open data for anyone to access use and share.
2. While there are currently over 80 countries with satellites in orbit[23], only a handful of those countries make their satellite data openly available[24]. This is despite the fact that openly published EO data has been shown[25] to drive economic growth, improve societal welfare, expand public and private research opportunities, support innovation, facilitate the education of new generations, and improve decision-making and transparency within government. Where public sector organisations are involved in multinational EO data collection programmes, the Commission should advocate for data to be published to open standards, as openly as possible.
3. Access to EO data will help UK businesses grow skills in, and develop products and services that use, feature detection in different domains, such as agriculture, housing and energy. For example, EO data can be used to tally the number of oil storage tanks in a particular country to produce estimates of consumption patterns and farmers can estimate global crop yields[26]. It can also be used to help human rights campaigners track population flows or environmentalists to track deforestation in remote wildernesses.
4. The Commission should recognise that access to EO data is particularly important during crisis events, such as flooding and fire[27], and that making this data available openly will allow for a faster and more effective response to these crises.

Q7. Which new technologies should the commission focus on to provide new opportunities to process and exploit geospatial data for economic growth?

23 http://www.unoosa.org/oosa/osoindex/search-ng.jspx?lf_id=

24 https://cdn-images-1.medium.com/max/1400/1*K6CYCDP1YXieYF-fzeegOw.jpeg

26 https://www.afr.com/technology/how-cubesat-satellites-are-changing-the-world-and-your-privacy-20180219-h0wcol

27 https://www.tanka.com/

1. New technologies present opportunities to process and derive insight from geospatial data in new ways.
2. For example, the application of Artificial Intelligence (AI), Machine Learning (ML) and related technologies is making it easier to extract greater value and insights from geospatial data.
    a. These technologies can be used to identify and extract features like road signs, street names and populated areas from images or even videos. For example, Skynet[28] (the machine learning platform of Development Seed[29]), uses machine learning to extract valuable insights from satellite and drone imagery. Similarly, Tanka[30] is using satellite imagery and a suite of AI techniques to detect fires and automate response procedures.
    b. When applied to satellite imagery, companies can use these techniques to automatically detect infrastructure such as roads or electrical lines, identify objects like ships or airplanes, locate important facilities like hospitals or schools and evaluate crop performance or monitor deforestation. At present, many of the organisations leading in this area are from the private sector. In some cases, the commercial firms developing these techniques are working with public sector organisations to tackle pressing, real-world problems. For instance, using computer vision techniques, the Facebook Connectivity Lab[31] and the Center for International Earth Science Information Network (CIESIN)[32] have produced detailed maps of the distribution of buildings and populations in rural regions of 18 countries across the globe. The maps, which the World Bank have described as[33] "unprecedentedly high-resolution", were generated at-scale, and can help governments and NGOs develop a more complete picture of population distribution when combined with information gathered from traditional government surveys and censuses.
    c. When applied to ground-level imagery, on the other hand, machine learning, computer vision and deep learning techniques can help organisations automatically identify important features of the world around us. Google's Street View[34] and Mapillary[35], for instance, use deep learning to extract valuable data like street and business names, addresses and front entrances of buildings from their databases of street imagery. This data can be crucial for delivery companies where knowing the exact entrance of a business or residence can save time and money.

34 https://ai.googleblog.com/2017/05/updating-google-maps-with-deep-learning.html
35 https://www.mapillary.com/

d. In 2018, the ODI published a report[36] on the array of models being used by organisations to develop AI systems. This included proprietary algorithm models (using a closed algorithm and open data) and open models (using an open algorithm and open data). The report recommended that the sharing and opening of data in ways that secure and safeguard the trust of people will be vital to building, implementing, and operating AI systems.

3. As well as presenting opportunities for making use of existing data more effectively, the Commission should focus on new technologies and approaches that could be used to collect or maintain geospatial data more effectively. For example, it is increasingly easy for organisations to collect geospatial data with low-cost satellites, cheaper LIDAR[37] sensors, and GPS-enabled devices. Meanwhile, collaborative collection and maintenance models can increase quality and reduce costs[38].

Q8. How can geospatial data and applications be used to support enhanced roll-out of future technologies?

1. A number of emerging technologies require access to geospatial data infrastructure in their development and adoption. CAVs, for example, require access to a wide range of geospatial data types from different sources[39] including: terrain data (related to elevation and terrain type); network data (such as maps and data about the road network); place data (including points of interest); real-time data (about traffic, construction and other incidents); and sensor data (such as in-car cameras and LIDAR).
2. Access to this data is therefore critical if the UK is to lead in the development and adoption of CAVs and other emerging technologies. This will complement other UK Government investments in these technologies, such as through the Industrial Strategy.

Q9: What are the options for how public sector organisations could continue to invest in maintaining and enhancing our geospatial data assets?

36 https://theodi.org/article/the-role-of-data-in-ai-business-models/
37 https://en.wikipedia.org/wiki/Lidar
38 https://theodi.org/article/legislation-gov-uk-improving-the-uk-digital-statute-book-through-collaborative-maintenance/
39 https://www.nds-association.org/wp-content/uploads/20180605_NDS_AutonomousVehicleSymposium.pdf

1. The Commission should ensure that public sector organisations are committed to publishing open data and removing the friction caused by restrictive data licences.
2. Like our physical infrastructure, geospatial data infrastructure is owned and maintained by a variety of organisations[40] that span the public, private and third sectors. The stewardship of data infrastructure will continue to evolve in part due to developments in technology making it easier for more organisations to collect and manage data. We agree that "the Commission's Partner Bodies and other public sector organisations must, alongside their core functions, adapt to the evolving geospatial environment and support the ecosystem and market to innovate and grow".
3. We recognise that maintaining this commitment over the long term creates challenges in terms of how we ensure sustainable funding for stewardship and access to data assets from the public sector. These challenges are not unique to geospatial data. For example, national meteorological services around the world are facing similar challenges around how they deliver on a public task which is best supported by openly licensed data[41], whilst ensuring that they can continue to invest in data collection and support use of that data by the widest possible set of consumers.
4. Debates about whether to charge licensing fees for access to public sector geospatial data continue, even when the value of making it open are well documented. Research commissioned by the ODI and completed by Lateral Economics used examples, such as US Landsat data[42], to show that open data will provide an extra 0.5% of GDP than data that people have to pay for[43].
5. The Commission should work with public sector organisations to explore different business models - in particular those that represent alternatives to fees generated through restrictive licensing - that will help to ensure sustainable collection and the provision of access to open geospatial data, such as:
    a. charging for warranties and quality assurance;
    b. charging for support and consulting around use of data;
    c. charging for API access and/or tailored online services to enable on-demand use of data within specific sectors or types of application;
    d. charging for specialised data collection or resurveying of data;
    e. collaborative maintenance and shared curation of data to remove duplication and increase data quality, accuracy and timeliness.
6. The Commission should support debate on the roles of central and local government in maintaining and enhancing our geospatial data infrastructure. There is a wider need for more understanding of whether devolved administrations, city-regions and local authorities in the UK have the right level of powers in the context of data collection, use and sharing. Decisions about data

40 https://theodi.org/article/who-owns-our-data-infrastructure/

41 https://www.metoffice.gov.uk/binaries/content/assets/mohippo/pdf/data-provision/odi-the-state-of-weather-data-infrastructure.pdf

42 https://www.fgdc.gov/ngac/meetings/december-2014/ngac-landsat-economic-value-paper-2014-update.pdf

43 https://theodi.org/article/research-the-economic-value-of-open-versus-paid-data/

should often be made by those closest to the decision; greater devolution for some powers may enable greater democratic involvement, for example through devolved national administrations and city-region mayors. The Commision should explore where, why and which functions or aspects of public sector geospatial data infrastructure should be at local, national and multinational levels and how to ensure appropriate funding at those levels.

Q10: What areas of the underpinning geospatial infrastructure such as positioning technologies, including GPS and indoor positioning systems, and geodetic networks and frameworks to support them, should we be prioritising the development of, in order to support the emerging requirements for geospatial data?

1. No response to this question.

Q11: What role should the private sector have in both the development and maintenance of the underpinning infrastructure and enhancing the UK's geospatial data assets?

1. In addition to public sector organisations, the private and third sectors play a role in maintaining and enhancing the UK's geospatial data infrastructure.
2. Private sector organisations such as Google, Microsoft, Apple and Facebook provide mapping services for developers building applications around their respective platforms, making it easier to integrate maps and location data into their products. Google and Microsoft also provide a number of general purpose mapping APIs that provide access to additional features, including routing and business listings. All of the major platforms use a mixture of open and non-open sources to build their mapping services, and many are investing in additional methods of data capture and collection to improve their offering, allowing them to provide not just 2D maps, but 3D models, street view and access to satellite imagery.
3. The proliferation of GPS-enabled smartphones and devices (connected to a global network of GPS satellites) means that it is now possible to capture

information about where people go, how long it takes them to get there and for how long they stay. Companies like Strava[44], a social network for athletes, Garmin[45], a GPS-technology company, and Uber[46], a ridesharing and transportation company, are able to use this location data to generate detailed maps from people's movements. Google is able to collect telemetry data through Google Maps[47] and, depending on user settings, the Android operating system. Telecoms providers collect similar types of data.

a. Data collected by private sector organisations using GPS-enabled smartphones and devices could inform decisions about public transport services, investment in physical infrastructure and much more. City planners and transportation authorities, for instance, argue that they could gain useful insights[48] from the data collected by private sector organisations about how people move through and interact with public infrastructure like roads, tunnels, transport networks, walkways and public spaces.
b. There are already some initiatives underway to make data of this type more widely available to public sector organisations, communities and people. Strava has launched Strava Metro[49], a toolkit available to city planning departments that provides a detailed view of pedestrian and cycling journeys across urban and rural areas. City planners and departments of transportation are provided with subscription-style[50] access to data about routes, wait times at intersections, periods of peak travel and even the starting and ending points of journeys within various regions. Uber[51] has responded to repeated requests from public sector organisations and civil society for access to the data it has collected by launching Uber Movement[52], an online platform that enables analyses of aggregated journey patterns.
c. Paid data-sharing agreements and proprietary tools will not satisfy the demands that all cities have for data[53]. In 2017 New York's Taxi and Limousine Commission introduced rules requiring rideshare and livery companies, including Uber and Lyft, to share detailed data about their passengers' journeys on a regular basis. UK Government and local

50 https://www.fastcompany.com/90149130/strava-the-app-for-athletes-is-becoming-an-app-for-cities
51 https://www.inverse.com/article/26156-uber-movement-mapping-app
52 https://movement.uber.com/?lang=en-GB
53 https://www.citylab.com/transportation/2017/01/finally-uber-releases-data-to-help-cities-with-transit-planning/512720/

authorities have legislated bus operators to open up data after other attempts to persuade them to do so failed[54].

d. By making data as open as possible, private sector organisations can support decision-making and drive innovation. Citymapper began publishing open data in 2017 about its Smartbus routes, stop locations, schedules and real-time arrival predictions. CityMapper was built using open data and the organisation sees the value of releasing their own – it "encourages all transport operators to make their data freely available to enable innovation and accessibility".

e. In some cases, there will be valid reasons why the data cannot be made available as open data, or made more widely available at all – for example, the risk of re-identification of individual people whose journeys are described in the data. As we detailed in a 2018 report, 'Personal data in transport: exploring a framework for the future', journey data is personal data[55]. The journeys people take can be used to infer where they work, shop and live - even where their children go to school. One recent study, for instance, demonstrated that it is possible to identify 95% of people in a dataset using only four spatio-temporal data points[56]. There is an ongoing challenge to find the level of aggregation and/or access that enables data to be as open as possible while protecting privacy and commercial confidentiality.

f. The Commission should explore best practice in terms of increasing access to this type of data and ensure that public sector organisations have appropriate guidance and powers to gain access (such as mandating the publication of open data or data sharing through procurement and licensing/operational conditions for the services they provide).

4. The Commission should support broader debate around the respective roles of public, private and third sector organisations in maintaining and enhancing the UK's geospatial data infrastructure, and the expectations of what types and level of services it could or should provide. The pace of innovation in terms of data collection and analysis creates a risk that private sector organisations may outstrip the ability for public sector organisations to do the same. There is the possibility that commercial sources could supplant or replace public sector data stewards because they provide higher quality data or services that better meet users needs with closed datasets (as evidenced by the widespread adoption of Google Maps). The potential impacts of geospatial data infrastructure becoming controlled solely by the private sector - such as unprofitable parts of the market, or country, being left underserved - should be explored by the Commission.

55 https://docs.google.com/document/d/1eBe_hM6lnWf2J_Syco1Gz86fvG7BZpjGF8kNYvw0aaI/edit#

56 https://www.nature.com/articles/srep01376

5. There are ongoing debates about whether nations are receiving an equitable share of benefits from technology and data use, with most focussing on the possible creation of a financial "tech tax"[57]. Governments should also be exploring how to create greater non-financial benefits from large tech firms, particularly given that their size and competitive power means that they can carry a higher compliance burden than other organisations. The Commission should consult on whether public sector organisations should have powers to mandate access, use and sharing of data - in defined ways - held by large firms (perhaps defined as organisations with data about more than 1m UK citizens) for the public benefit. This would be a parallel to the powers that ONS have under the Digital Economy Act to secure data for use in national statistics[58].

Q12. Do you face challenges when working with geospatial data from across the public sector? If so, what are they and how could value be better released? Are there any technical remedies or standards that could be adopted to improve the interoperability of geospatial data? Please provide supporting evidence of what these remedies could help to accomplish.

1. In February 2018, the ODI, in collaboration with a cross-government team, organised and ran four workshops across the UK with geospatial data users. The workshops identified a number of challenges faced by users of OS data, including SMEs and startups, local authorities and other public sector organisations, educational organisations and members of the open data and OSM community[59]. The challenges are similar to those to be tackled by a recently-announced Hydrographic Office project[60].
2. The Commission should continue to engage with data users to support the development of technical remedies or standards to improve the interoperability of geospatial data. These should include:
    a. public sector organisations committing to increase the publication of open data and remove the friction caused by restrictive data licences. Data assets the Commission should prioritise on are described in our response to Question 4.
    b. where data is not available under open licences, public sector organisations developing better understanding of the impacts of non-open licences[61] and working with their community to discuss and clarify licensing issues (particularly in relation to derivative works). New open

57 https://www.bbc.com/news/business-45813754

60 https://www.gov.uk/government/news/uk-hydrographic-office-to-unlock-the-value-of-location-based-information-as-part-of-geospatial-commission
61 https://theodi.org/article/what-are-the-impacts-of-non-open-licences/

data released from public sector organisations may help to unlock other data releases, however increased access to non-open data might exacerbate existing problems unless steps are also taken to simplify and clarify its licensing.

Q13. How can the Geospatial Commission act as a more effective customer for geospatial data on behalf of the public sector?

1. A number of OS products are made available for free use by public sector bodies via the Public Sector Mapping Agreement[62]. We agree that the Commission should "continue the work that was started by Department for Business, Energy and Industrial Strategy (BEIS) to renegotiate the current Public Sector Mapping Agreement".
2. In particular, the Commission should ensure that the geospatial data accessed under the agreement is free from restrictions related to derivative works. Signatories of the Public Sector Mapping Agreement - as other agreements such as as the One Scotland Mapping Agreement, PAF Public Sector Licence and the Aerial Photography Great Britain contract - should be free to create derivative work and release this as open data. This is important to support the goals of public sector organisations, several of which have a commitment to publishing more open data.

Q14. Are there any additional geospatial datasets, from the other partner bodies or other sources, that the public sector would derive significant benefit from having access to, that might have novel and valuable use cases? What would that access look like?

1. The Commission should continue to engage with public sector data users to understand the data assets they could derive benefit from having access to.
2. As well as public sector organisations, the Commission should consider the potential benefits of increasing access to data held by private sector organisations.
    a. As described in our response to Question 11, this data could include data held by organisations that provide provide mapping services and aggregate data collected by organisations using GPS-enabled smartphones and devices.

62 https://www.ordnancesurvey.co.uk/business-and-government/public-sector/mapping-agreements/public-sector-mapping-agreement.html

b. Valuable data might also include locations of services and amenities that the public sector doesn't own or operate, but should know about for planning and statistical purposes, such as food outlets, bank branches and ATMs, pharmacies and nurseries.

Q15: How can we best develop a single UK strategy, ensuring alignment between the individual strategies across the UK while still allowing for regional variations?

1. The Commission, and the National Geospatial Strategy it will produce, represent an opportunity for central commitment, governance and coordination to strengthen the UK's national geospatial data infrastructure.
2. The Commission should work with devolved national administrations and local government to understand the roles of different layers of government in maintaining and enhancing our geospatial data infrastructure. There is a wider need for more understanding of whether devolved administrations, city-regions and local authorities in the UK have the right level of powers in the context of data collection, use and sharing. Decisions about data should often be made by those closest to the decision; greater devolution for some powers may enable greater democratic involvement, for example through devolved national administrations and city-region mayors. The Commision should explore - and encourage experimentation with - where, why and which functions or aspects of public sector geospatial data infrastructure should be at local, national and multinational levels.
3. The Commission will also need to work closely with other central government organisations and groups in the development of the National Geospatial Strategy. This should include the Department for Digital, Culture, Media and Sport (DCMS) and its team working on the National Data Strategy, Cabinet Office (Government Digital Service), BEIS, ONS, and the Ministry of Housing, Communities and Local Government (MHCLG).

Q16: How can we best ensure effective local authority coordination and sharing of best practise, using location data to better deliver public services?

1. In 2018 the ODI conducted research into the role open data plays in the delivery of public services[63]. The research highlighted three high-level patterns for the ways that open data - including geospatial data - can be used to deliver public services:
    a. using open data to increase access to services for citizens or organisations;
    b. using open data to plan public service delivery and make service delivery chains more efficient;
    c. using open data to inform policymaking.
2. The research also produced a series of recommendations to support greater use of open data to deliver public services. In particular, the Commission should consider the following recommendations in the context of geospatial data:
    a. **Organisational collaboration**. The availability of funding for activity is a key determinant of activity. We received 24 responses to the invitation to tender for the local authority Stimulus Fund aspect of this project - we could have funded more consortia if we had had the resources to do so. There is clearly appetite within local government to undertake experiments in this area but there are funding challenges. The Commission should consider funding further activity in this area to help develop new use of geospatial data and deliver better services to citizens, and also to strengthen peer networks between authorities.
    b. **Data infrastructure, digital skills and literacy.** In the fieldwork, participants referred to the GDS leadership on service design as best practice, such as the curriculum for the GDS academy and the GDS service design manual. As part of the expansion of the curriculum of service design training towards covering data and technology roles and digital competencies, the Commission should consider supporting the development of learning materials specific to the use of geospatial data, including content to help those in non-technical roles understand how open data can support services at a strategic level.
    c. **Peer networks**. Access to environments for networking and sharing best practice[64] across different organisations was deemed essential to developing new ways of using data to deliver public services. The Commission should make use of existing, and where necessary convene new, networks of those who are interested and involved in using geospatial data for public service delivery.

Q17: As a result of this analysis, we are prioritising the exploration of possible initiatives in the high-value categories identified:

- **property and land**

63 https://theodi.org/article/using-open-data-for-public-services-report-2/
64 https://theodi.org/method-report-peer-networks-for-open-data-leaders

- **infrastructure and construction**
- **mobility**
- **natural resources**
- **sales and marketing**

What are the existing or potential geospatial applications which could be scaled-up or developed in order to capture economic value? (We would particularly welcome responses from industry and other bodies engaged in these sectors.)

1. No response to this question.

Q18: Are there any other areas that we should look at as a priority?

1. No response to this question.

Q19: What are the main potential private and public sector innovations that will rely on the use of geospatial data to rollout, and are there corresponding regulatory challenges?

1. No response to this question.

Q20: How best can we make the UK's presence in the international geospatial world more visible?

1. No response to this question.

Q21: Where should the UK be looking for points of comparison overseas? Who are the other international exemplars? What best practice is being modelled overseas that we can learn from?

1. Some developments we recommend examining for points of comparison and best practice internationally are:
    a. the Australian government's steps to open up a wide range of geospatial datasets and resources. Following the 'Declaration of Open Government'[65] in 2010, the Digital Transformation Agency (DTA)[66] created data.gov.au[67] as a means of finding, accessing and reusing public government datasets, including geospatial datasets. At the time of writing there are over 5,500 datasets[68] from GeoScience Australia alone. In 2014, the DTA launched National Map[69], an online service that allows users to search through a catalogue of geospatial datasets made openly available by public agencies and overlay them on a three-dimensional map of Australia. The following year the Australian government released a 'Public Data Policy Statement'[70] reaffirming and formalising its commitment to making "non-sensitive data open by default" with the aim of contributing to "greater innovation and productivity improvements across all sectors of the Australian economy".[71] More recently, the government has released

71 https://www.pmc.gov.au/resource-centre/public-data/australian-government-public-data-policy-statement

PSMA's[72] Geo-coded National Address File (G-NAF)[73] as well as their Administrative Boundaries datasets[74].

b. The European Union's (EU) progress in opening up geospatial data. In 2011, following a string of policies supporting open data[75], the EU published a communication[76] that pledged to open up data as "an engine for innovation, growth and transparent governance" and pointed to geospatial data as an explicit example of the value of open data. The European Space Agency (ESA) has recently received praise for committing itself to opening up some of its satellite imagery[77]. In 2014, the ESA announced[78] that it would provide "free, full and open access" to data from the Copernicus programme[79], including data collected by the new Sentinel series[80] of satellites. The ESA has since launched the 'Copernicus Open Access Hub'[81], an online platform that provides access to data from all current Sentinel missions through both an interactive graphical user interface and an API.

c. The United State's commitment to open geospatial data is the archive of US Landsat imagery[82], which was made openly and freely available in 2009. The global economic benefit of opening up access to this nearly fifty year archive of imagery of the Earth's surface was estimated to be[83] $2.19bn in 2011 alone. These benefits were spread across 38 different primary application areas and stemmed from things like improved long-term environmental planning and monitoring, improved decision making, better enforcement of regulations and increased human safety.[84] Despite commendable gains[85] in the years since the 2009 open data policy was implemented, there is currently uncertainty[86] as to whether this commitment to open government, and by extension open geospatial data, will continue under the present administration.

86 https://sunlightfoundation.com/2018/01/24/under-trump-u-s-government-moves-from-open-to-closed/

2. The Commission should also look for, and learn from, best practice demonstrated by UK organisations and groups in an international context. For example, OSM has become a key component of international geospatial data infrastructure. Local and national governments around the world are working with the OSM community to ensure that their geospatial data is available to that community and the growing ecosystem it supports. Large commercial organisations like Apple, Microsoft and Facebook build OSM into their mapping services[87], and companies like Lyft, Telenav and Mapbox are using it as essential part of their products.

Thank you for your time in completing your response to our call for evidence.

Any questions, please get in touch with the Geospatial Commission via geospatialcommission@cabinetoffice.gov.uk

[87] https://theodi.org/article/how-are-facebook-apple-and-microsoft-contributing-to-openstreetmap/

Government launch call for evidence to be geospatial world leader: OSGeo:UK Response

Questions:

Please select which of the following best describes you as a respondent:

Respondent	Please mark with a X
Academic	
Business representative / trade body	x
Central government	
Charity or social enterprise	x
Individual	
Legal representative	
Local government	
Large business (over 250 staff)	
Medium business (50 to 250)	
Small business (10 to 49)	
Micro business (up to 9)	
Other - please state	

Call for evidence - three key themes

We have identified three high-level themes that could help our approach to setting a strategy which are as follows:

1. Supporting innovation in the geospatial sector, exploring how to secure cutting edge skills, the right access to data, and opportunities from emerging technologies for the geospatial sector itself
2. Enhancing the UK's geospatial assets, looking at how best to align interests, avoid duplication, and instill best practice across the whole public sector
3. Driving investment and productivity in geospatial applications, asking in which wider sectors the most value lies from better exploitation and use of geospatial data, in the UK and internationally

Our questions

Q1. Is our view of the geospatial data types accurate? If not, what should be included or excluded from this?

Yes

Q2. In addition to current government policy, what are the areas of geospatial skills where the commission could best focus, to help ensure the necessary capability within the UK for the future?

Geospatial skills must be general and fundamental, rather than skills in the use of specific software. We note with great concern agreements brokered between commercial software vendors and UK universities and UK Schools to supply proprietary GIS to all students. This stifles education and innovation in the UK geospatial sector.

Free and open source alternatives (FOSS) to proprietary software must be given equal weight in all state-supported education and training, thereby removing financial and licensing barriers to innovation by individuals with strong skills but limited access to budgetary and legal resources.

Much of the current explosion in the uptake of Earth observation (EO) is being led by organisations (specifically start-ups) in the United States and Europe. These companies are doing this through the use, creation and sharing of open source software. If the UK is to become a major player in the Earth observation and geospatial sector then more needs to be done to make UK developers and scientists the creators of open software rather than

just users. Some might argue that the UK has a strong EO sector, but it is way behind in terms of what is currently leading technology as it is too dependent on a slow moving, project-based model. Support for open source, and strengthened geospatial skill development could enhance the position of UK EO.

Q3. What are the geospatial skills needs and gaps in your organisations, how can these be most effectively addressed, and how can careers in the sector be best promoted?

Given the increasing role of web technologies and version control in facilitating collaborative software development, plus the ability of free and open systems to democratise progress in software development, web-based computing is key to the flourishing of geospatial technologies.

Spatial databases are vital in delivering high quality spatial systems, and the success of open source packages such as PostgreSQL and in particular the spatial extensions PostGIS and PGRouting, should be implemented and promoted by government systems.

Careers in the sector could be promoted by including elements of the geospatial FOSS software stack in the secondary curriculum for geography and computer science. By freeing users from privatised solutions, innovation can be accelerated and the workforce and the workplace will benefit from incremental gains in much the same way scientific progress stems from information and technology sharing.

Many organisations now advertise for positions where a knowledge of and experience in FOSS software is required. Engaging with universities and trade bodies to create nationally and internationally recognised qualifications in open source software would help applicants and recruiters.

Spatial analysis is increasingly moving away from the graphical user interface (GUI) and into the realm of computer science. The Python computer programming language is common to both the leading proprietary and open source GIS software applications, making Python coding skills highly applicable in GIS. The proliferation of the R programming language has spread from the academic environment into the other sectors, with dedicated geospatial functions as well as an expanding library of packages written by the geospatial community. Using programming scripts to process and analyse data makes workflows more robust and reproducible, and the GIS jobs market is demanding programming skills from applicants. It will be important to offer programming skills to current professionals to ensure that they are not left behind recent graduates with recent programming experience.

Q4. Are there any publicly or privately-held geospatial datasets that are currently challenging to access or use or of insufficient quality, but which you

or your organisation would find valuable if these issues could be resolved? Please explain why this would be of value, and how access/quality could be improved?

The licensing around some Environment Agency datasets such as flood zones is unclear, which means that usage is low. Other datasets such as transport timetables is available in different formats, with different access and licensing constraints across the country, making it difficult to integrate in country-wide solutions. More usage of this data in particular would encourage greater use of public transport.

Other datasets of high value include land ownership and current data on location of underground services in the North Sea, such as pipelines, power cables and telecoms. In general this is still either proprietary or “as-planned”, and now out of date

A large number of environmental datasets are made available only for non-commercial use. Climate change related datasets, hydrology and soils data would all be valuable if made truly open data.

Several environmental datasets are not accessible to the Third Sector. Such datasets include the Centre for Ecology and Hydrology (CEH) Land Cover Map Vector data, the Cranfield University NATMAP Vector data, the rural Land Registry field margins and the Rural Payment Agency data on Agri-Environment Schemes, which are subsidised by the taxpayer. Licences for these datasets treat non-profits as businesses when they should be treated akin to academic research institutions for which the data are more readily accessible. This is particularly pertinent when charities are working to help the government achieve its own commitments, for example under international treaties such as the Convention on Biological Diversity and the Sustainable Development Goals.

Q5: Do you anticipate that any changes will be needed to the both address data and the wider address ecosystem, to support emerging technologies? Please provide evidence of value to support any proposed changes.

Address data and standards must be fully open (see https://www.owenboswarva.com/blog/post-addr2.htm for a summary of the current situation). Proprietary solutions such as What3Words should not be promoted as alternatives. They cannot be relied upon to be sustainable in the long-term as they are closed source.

Address Base data should be made more easily available, to enable applications to identify UK properties beyond the front letterbox, which is as far as postcode address file currently reaches.

Open and up to date information on the location and collection times of post boxes would be an extremely useful dataset. The ability to query this information through a web (or

voice-enabled) interface would be extremely valuable, particularly to at risk or elderly people.

Q6: How should the commission be looking to develop the UK's capability in Earth observation data, both technologically and to support an effective market?

The global Earth observation sector is rapidly changing, and those organisations that are deriving most benefit are using open data and open source software. UK universities have been too slow to react to this, and more graduates are required who understand the interface between IT and Earth observation science, and have a better understanding of, and desire to code. Vast amounts of open data are now available, but future development in the sector will depend on creating applications for time series data and having the knowledge to understand how best to manage and deliver those data.
The commission could help link education establishments and SMEs (a wide range of SMEs rather than the usual players) to create and deliver (in tandem) course content that would result in a young labour force with desirable, transferable and much required skills. A commission-sponsored degree and/or professional certificate would, if properly implemented, demonstrate a commitment to growing and enhancing geospatial skills in the UK. Open source software should be a key component of all future courses.

The availability of free and open earth observation data is critical to the development of this sector.

Q7. Which new technologies should the commission focus on to provide new opportunities to process and exploit geospatial data for economic growth?

The commission could focus on the accessibility and availability of the geospatial datasets as outlined above, which would enable SMEs, Charities and Academia to focus on the development of the technologies and provide the economic growth. Additionally, focusing on the promotion of FOSS software would be valuable across the board rather than specifically to one sector or another.

Q8. How can geospatial data and applications be used to support enhanced roll-out of future technologies?

The example of AddressBase going open is a good example of how commerce can better find and complete the addresses of their customers.

Further development to intelligent transport routing, which uses geospatial information to re-route road traffic to a greater extent, may improve performance of road infrastructure.

Q9: What are the options for how public sector organisations could continue to invest in maintaining and enhancing our geospatial data assets?

Open licences could enable public servants to develop public software collaboratively and enhance their communication with each other and vendors, rather than filtering their requirements, communication and finances through legacy vendors who run large legacy systems that currently dominate government geospatial applications (such as in proprietary development management solutions).

By opening, and modularising geospatial systems, smaller vendors may be able to provide smaller solutions that contribute to, and maintain, public service solutions as platform type solutions rather than vendor-specific monolithic software architectures.

Long term plans for investment in and support of open solutions would be beneficial - too many platforms have received funding for development but no longer term funding for implementation, which is wasteful of finite resources and fails to demonstrate some of the excellent open source work being undertaken in Government.

Q10: What areas of the underpinning geospatial infrastructure such as positioning technologies, including GPS and indoor positioning systems, and geodetic networks and frameworks to support them, should we be prioritising the development of, in order to support the emerging requirements for geospatial data?

80 Muswell Road, London, N10 2BE
osgeouk@gmail.com

Remain a member of the existing European GPS network. Creating our own (a Brexit proposal), would be a colossal duplication of effort and hence a massive waste of money.

A small firm called wayfindr is trying to develop a standard for indoor navigation based on radio beacons for helping people move around large public spaces such as train stations.

If an open standard were agreed, this could create an opportunity for small vendors to contribute to its development, rather than rival companies trying to promote their own patented solution and aggressively compete for market share, which could end up with different beacon systems being used in different train stations for example.

https://www.wayfindr.net/open-standard

Q11: What role should the private sector have in both the development and maintenance of the underpinning infrastructure and enhancing the UK's geospatial data assets?

The private sector could be encouraged to contribute to open datasets and solutions in contracts. For example, they could contribute to an open AddressBase geocoding solution, which will be of benefit to them enabling the geolocation of their customers' homes with greater accuracy.

Q12. Do you face challenges when working with geospatial data from across the public sector? If so, what are they and how could value be better released? Are there any technical remedies or standards that could be adopted to improve the interoperability of geospatial data? Please provide supporting evidence of what these remedies could help to accomplish.

- Adoption of open licences
- Removal of rate limits etc
- Simplify discovery by reducing the complexity of data stores or portals: often a list of dataset addresses is all that is required
- Web/mobile developers tend to prefer latitude and longitude for data and web mercator for tiles, yet many systems record spatial information in british national grid, a developer-friendly reusable shared solution to reproject between coordinate systems may improve the link between data and frontend development

Q13. How can the Geospatial Commission act as a more effective customer for geospatial data on behalf of the public sector?

By promoting and improving standardised data formats, for example in the recording of planning records, or indeed any public service data that includes geospatial information and making metadata on their datasets readily available.

Q14. Are there any additional geospatial datasets, from the other partner bodies or other sources, that the public sector would derive significant benefit from having access to, that might have novel and valuable use cases? What would that access look like?

High resolution, frequently updated satellite and aerial imagery
A coordinated involvement in OpenStreetMap, helping to improve their data?
Detailed soils data

Question 15: How can we best develop a single UK strategy, ensuring alignment between the individual strategies across the UK while still allowing for regional variations?

By taking the government as a platform approach to centralisation (standards, coordination) and localisation (implementation, inter-communication)

Q16: How can we best ensure effective local authority coordination and sharing of best practise, using location data to better deliver public services?

- Promote the need for spatial professionals (either through experience or qualification) at all levels including managerial
- Open standards
- Open licences
- Providing opportunities for public servants to collaborate on shared solutions
- Providing opportunities for small vendors to contribute via standardised record management (i.e. open standards for service delivery systems)
- Simplified procurement for SMEs and a move away from always using larger commercial organisations

Q17: As a result of this analysis, we are prioritising the exploration of possible initiatives in the high-value categories identified:

- **property and land**
- **infrastructure and construction**
- **mobility**
- **natural resources**
- **sales and marketing**

What are the existing or potential geospatial applications which could be scaled-up or developed in order to capture economic value? (We would

particularly welcome responses from industry and other bodies engaged in these sectors.)

Q18: Are there any other areas that we should look at as a priority?

See Q2 above: levelling the playing field in education for spatial applications between proprietary and open-source

Q19: What are the main potential private and public sector innovations that will rely on the use of geospatial data to rollout, and are there corresponding regulatory challenges?

Q20: How best can we make the UK's presence in the international geospatial world more visible?

- By supporting an excellent spatial event such as FOSS4G
- By innovating open standards (see Open311 for example, which was founded by Code4America and is now used internationally, including for fixmystreet's own middleware to improve the british public space)
- By hiring innovative organisations, ideally in groups rather than single vendors to deliver high-profile government geospatial solutions, and allow those innovative organisations to flourish and collaborate

Q21: Where should the UK be looking for points of comparison overseas? Who are the other international exemplars? What best practice is being modelled overseas that we can learn from?

- New York City planning labs (https://medium.com/nycplanninglabs/nyc-planning-labs-one-year-in-1f4c8cbd73aa)
- Philadelphia analytics (http://analytics.phila.gov/)

24th October 2018

To whom it may concern

Re: National Geospatial Strategy – call for evidence

Thank you for the opportunity to respond to this consultation. OpenStreetMap United Kingdom (OSM-UK) is supportive of efforts to drive the move to use public and private sector geospatial data more productively. We believe that the global, open and collaborative nature of the OpenStreetMap project has a pivotal role to play in unlocking extra value for the economy every year.

Our vision is one in which access to geospatial data is universal and where barriers that prevent individuals or organisations from using, innovating with, and delivery value from geospatial data are fully removed. This vision can be delivered via greater collaboration and openness. We therefore welcome all opportunities to work with the commission, the geospatial industry and the OpenStreetMap community to resolve current issues and to help us realise this vision.

About us

OpenStreetMap United Kingdom (OSM-UK) represents the interests of the OpenStreetMap community in the United Kingdom, the Isle of Man and the Channel Islands. Our members contribute to, are users of, or otherwise have an interest in, the OpenStreetMap project.

The OpenStreetMap project was founded in the UK in 2004, with the goal of creating an openly licensed map of the world. It has subsequently grown to become one of the most successful collaboratively maintained open datasets in the world. This success has meant that OpenStreetMap has become part of the global geospatial data infrastructure and is supported by a rich ecosystem of individuals, community groups, small businesses and multinational organisations.

As a not for profit community interest company, we are delighted to be able to support our community and we will strive to be a leading player within the OpenStreetMap project. We aim to:

- Increase the quality and quantity of data about the UK in OpenStreetMap.
- Improve and increase the size, skills, toolsets and cohesion of the OpenStreetMap community in the United Kingdom.

- Promote and facilitate the use of OpenStreetMap data by individuals and organisations in the United Kingdom.
- Promote and facilitate the release by organisations in the United Kingdom of data that is suitable for use in OpenStreetMap.

Our relationship to the OSMF

The OpenStreetMap Foundation (OSMF) is an international non-profit organisation supporting but not controlling the OpenStreetMap project. Although the OSMF is also a company registered in England and Wales, it's scope is global.

We became a Local Chapter of the OpenStreetMap Foundation (OSMF) in 2017. The agreement established a framework of mutual support and recognised that OSM-UK will represent the interests of the OpenStreetMap community within our designated geographic region as defined above.

Earlier this year OpenStreetMap Ireland officially formed as a company limited by guarantee. We understand that they are also interested in becoming a Local Chapter of the OSMF, likely covering the Island of Ireland. We have therefore consulted with OpenStreetMap Ireland in regards to our comments on Northern Ireland geospatial data. We will continue to work together on ensuring the best outcome for Northern Ireland's geospatial industry.

Response to the call for evidence

Please find our response to the call for evidence below. As noted above we welcome all opportunities to work with the commission, the geospatial industry and the OpenStreetMap community to resolve current issues. Please contact us via [Text redacted]as a first port of call.

Your sincerely,

[Text redacted]

Telephone	[Text redacted]

Please select which of the following best describes you as a respondent:

Respondent	**Please mark with a X**
Academic	
Business representative / trade body	
Central government	
Charity or social enterprise	**X**
Individual	
Legal representative	
Local government	
Large business (over 250 staff)	
Medium business (50 to 250)	
Small business (10 to 49)	
Micro business (up to 9)	
Other - please state	Members' organisation

Call for evidence - three key themes

We have identified three high-level themes that could help our approach to setting a strategy which are as follows:

1. **Supporting innovation in the geospatial sector**, exploring how to secure cutting edge skills, the right access to data, and opportunities from emerging technologies for the geospatial sector itself
2. **Enhancing the UK's geospatial assets,** looking at how best to align interests, avoid duplication, and instill best practice across the whole public sector
3. **Driving investment and productivity in geospatial applications**, asking in which wider sectors the most value lies from better exploitation and use of geospatial data, in the UK and internationally

Our questions

Q1. Is our view of the geospatial data types accurate? If not, what should be included or excluded from this?

We are broadly supportive of your view of geospatial data types. As noted in your call for evidence, the importance and demand for geospatial data is constantly evolving. The data and norms in place today are likely to be complemented by new data and processes in the future, some of which may not yet have even been conceived. We therefore support a wide-ranging view of geospatial data types noting that some of these are easier for the private sector to survey/measure (e.g. location of physical assets detected via advanced image recognition and commercial satellites), whilst others are more abstract or represent a legal or political construct defined and controlled by a public sector body (e.g. areas of land with a legal status, political and administrative boundaries, address data). Any National Geospatial Strategy should focus on unlocking elements that are not as readily available to the private sector.

Q2. In addition to current government policy, what are the areas of geospatial skills where the commission could best focus, to help ensure the necessary capability within the UK for the future?

Data collection and data ownership.
Whereas in the past geospatial data has been the focus of public sector organisations (e.g. Ordnance Survey) who control the collection and rights ('ownership') of data, this is beginning to change and this is likely to accelerate in the future. Supporting geospatial skills related to data collection will ensure that the most value can be extracted out of techniques such as remote sensing, LiDAR, image recognition and crowd sourced (Volunteered geographic information). Training on data rights, ways to share data (formats, systems and licences) and appropriate business models for data will ensure frictionless movement of geospatial data between individuals, organisations and the public sector.

Schools and academia
Thinking about schools and academia, it is essential that the next generation are exposed to as wide a view of geospatial data as possible. The existing system focuses on traditional public sector data. This should be broadened to include data and experience from the private and volunteered geographic information sectors. Evaluating appropriate data sources and tools for each project, are skills that are valued in all sectors and so setting up the next generation with these skills and higher view across the sectors will equip them far better than focusing on a single provider's offerings.

Q3. What are the geospatial skills needs and gaps in your organisations, how can these be most effectively addressed, and how can careers in the sector be best promoted?

Firstly, understanding of data rights ('ownership') and licensing. This is particularly true of public sector data which can often be the output of complex chains of data processing involving multiple parties (e.g. local authority data which has not been wholly created by the local authority and may include the intellectual property of other bodies such as Ordnance Survey and Royal Mail). A good understanding of rights and licensing is often required when wanting to use this data. The system should be simplified so as to remove the skill barrier.

Secondly, data analytics and computer science. As larger volumes of data become available, and new techniques of data collection need to be developed, having the right analytical and computer science skills will become increasingly important.

Q4. Are there any publicly or privately-held geospatial datasets that are currently challenging to access or use or of insufficient quality, but which you or your organisation would find valuable if these issues could be resolved?

Please explain why this would be of value, and how access/quality could be improved?

Address data
This is a key area and we cover it in detail in our answer to question 5.

Ordnance Survey data
Whilst we are pleased to see steps to open up access to Ordnance Survey data under the Open Government Licence (OGL), we feel that this does not go far enough. In particular we are concerned that the plan to release some data "for free, up to a threshold, through an API" will result in continued barriers to access which could be avoided. We prefer a solution where all data is made availble (without threshold limits) under OGL. The commission and Ordnance Survey should explore appropriate business models that will enable this.

Planning and local highways/Street data
Planning, transport and street data held by Local Authorities plays a key role within our society, yet continues to be hard to access. Release of this data both at source and aggregated via a central hub, under an open data licence will support innovation and enhance democratic processes within the United Kingdom.

Within our answers to this consultation, we cover topics which, if implemented, will ensure maximum value of this data. This includes (1) publishing data which is joined together as a UK wide dataset and published on central hubs, (2) frequent updates or publishing "as live" via an API, and (3) collaboration with the end users and Volunteered geographic information sector.

As an example, the National Street Gazetteer (NSG) is regularly updated by all 174 highway authorities via a central hub (GeoPlace in this instance). This data should be made available via a full download extract and an API and should be under an Open Data licence. Functionality should be added to allow collaboration with the wider industry (e.g. initial centre lines could be provided by the construction industry, and potential errors could be flagged by all parties).

Excessive redaction of data
The Commission should ensure that national security and national critical infrastructure considerations are not used excessively or unilaterally to redact data releases. As an example, our members have been prevented from receiving locations of fire hydrants (despite them being entirely visible on the ground) and we feel that this is excessively restrictive. Knowledge of fire hydrant locations is not only beneficial from a safety perspective, but may also be of use in the insurance sector.

Natural monopolies
Private sector organisations which are natural monopolies (or can be considered as running an essential public service) include the utilities, rail and bus service, the Royal Mail amongst others. Many have access to rich geospatial datasets, which if made available as open data, would allow for greater innovation in key

industry sectors. There is little incentive under current regulatory frameworks to make this data available, let alone available as open data. The commision should explore the value of making this data more available, especially for those industries that are pivotal to other government strategies (e.g. utilities and public transport data can support the Clean Growth Strategy).

Licensing of private sector data
The introduction of the Open Government Licence for publicly held data has helped to increase the amount of open data being made available - held back now mainly by complex chains of data rights (IP on derivative work).

Our members continue to face challenges in the private sector. A government led standard waiver for private companies to publish their data would help. A very small example is retail store locations. Although it is possible to scrape this data from websites, the legal situation of doing so is unclear. Our members prefer to get explicit permission but this can be challenging with some companies misunderstanding that publicly accessible does not equate to open data.

Privatisation or oursourcing of public services
Finally, for data that is currently publicly held, the Commission should ensure that this remains accessible under an open licence in situations when public services are privatised or outsourced. Examples of where this has not been the case include the privatisation of Royal Mail and the use of infrastructure support service providers to maintain Local Authority street assets (street lighting, benches, etc).

Q5: Do you anticipate that any changes will be needed to the both address data and the wider address ecosystem, to support emerging technologies? Please provide evidence of value to support any proposed changes.

The country's postcodes are commonly used as a pseudo-identifier when matching positional data from different sources. We agree with the commissions observation that it is “the most commonly recognised form of an address by the public”. For emerging technologies to succeed it is likely that they will need to gain the support of the public. As such we believe that initial focus should at first be on providing greater and more frequent access to postcode and PAF data under an open data licence. It is our view that the PAF is a specific geospatial database and is included in the commission's view of geospatial data types (Question 1). Unlocking access to PAF will also ease the route to the open data release of the National Address Gazetteer; something which we are keen to see as soon as possible.

An additional and valuable first step would be the immediate release of Ordnance Survey’s “Code-Point with Polygons” data under an open data licence. Our members have identified a number of errors with the existing “Code-Point Open” dataset, often related to the introduction of new postcodes. A monthly release (or more frequently / as live) would help to ensure that corrections are published with less delay.

In Northern Ireland the Central Postcode Directory (CPD) maintained by NISRA, and Pointer (the address database) maintained by Land & Property Services (LPS) should be released as open data.

Furthermore, the recent trend in public sector (gov.uk) registers to provide address data only as a UPRN, must be stopped until the relevant UPRN data is also made available under the OGL. Since the public don't have access to the database that decodes these into full addresses, providing address data only as a UPRN removes much of the usefulness from address-containing datasets that are converted to registers. We believe it should be a requirement to have an openly licenced address register containing those UPRN records that appear in other gov.uk registers. A true open national address database is a must.

Thinking longer term, the rise of ‘floating transport’ (e.g. dockless bicycle hire schemes) and alternative delivery locations (e.g. parcel collection boxes, delivery to car boot) is likely to result in a change in the way we consider addresses. Ensuring that our systems are flexible enough to adapt to this change is important and will act as an enabler to new service offerings.

Q6: How should the commission be looking to develop the UK’s capability in Earth observation data, both technologically and to support an effective market?

To help support an effective market, the commission should look towards existing solutions that facilitate the sharing and discovery of existing earth observation data. As an example, the Open Imagery Network [1] enables contributors to share imagery and associated metadata. The resultant discoverable network of openly licensed imagery, helps to ensure that earth observation (imagery) data is available to a wide range of organisations.

We believe that openly licensed data aids an effective market and therefore, when data is collected for a publicly funded project, there should be a presumption that this data be made available under an open licence.

As drone imagery is often better than satellite imagery when a high resolution is required, the Commission should consider how best to support low altitude solutions as well as satellite technologies.

[1] https://openimagerynetwork.github.io/

Q7. Which new technologies should the commission focus on to provide new opportunities to process and exploit geospatial data for economic growth?

Technologies related to improved publication of geospatial data should be investigated. A move towards more collaborative working practices will ensure that public sector data can be more widely exploited. Our answers to other questions include suggestions that public sector data should be (1) joined together as a UK wide dataset and published on central hubs (e.g. GeoPlace), (2) updated on a more frequent basis or published “as live” via an API, and (3) should allow for collaboration with the end users and Volunteered geographic information sector. The commission should focus on technologies that make this possible.

More broadly, the commission should focus on those new technologies that are open and collaborative. This will ensure maximum use and ensures that any public expenditure is to the benefit of the wider economy rather than a small subset of the industry organisations.

Q8. How can geospatial data and applications be used to support enhanced roll-out of future technologies?

Geospatial data could be used in the decision making process about future technologies (e.g. deciding the best locations for Mesh WiFi on lamp posts, 5G rollout, electric vehicle charging point). Ensuring that as much data is open for anyone to use will allow innovation to flourish, rather than be stilted by lack of information.

Q9: What are the options for how public sector organisations could continue to invest in maintaining and enhancing our geospatial data assets?

Greater Cooperation
Public sector organisations should look towards more collaborative working practices. This includes within the public sector, but also greater collaboration with the private sector and Volunteered geographic information (VGI) community.

If we take public rights of way as an example, we can consider two separate stages - the maintenance of a record of the legal status of rights of way, and data about the condition of the rights of way.

Firstly on recording the legal status. As it currently stands, the record of a right of way’s existence is maintained by county-level councils, so there are over 100

different datasets, all in slightly different formats. Greater collaboration between local authorities would ensure that best practice is more widely adopted and that data formats are standardised. It would also ease the process of releasing this data as open data which some local authorities have actively pursued whilst others have wasted time on resource on fighting (and losing) FOI/EIR requests. Specifically on the point of releasing the data as open data: Local Authorities are required to submit their Rights of Way data to GeoPlace as part of the Local Street Gazetteer submissions. A collaboration whereby GeoPlace are responsible for releasing more open data would reduce the overhead incurred by each Local Authority acting independently. Note: to date GeoPlace have refused to provide access to this data, even though it would benefit their Local Authority joint owners.

Moving beyond the basic level information about a right of way, there is additional metadata that can be collected. This includes attributes such as the condition of the right of way, any obstructions and ease of access to users with reduced mobility. The trend over recent years has been to reduce the number of Rights of Way Officers employed by the public sector. Greater collaboration with the private sector and the VGI community, will ensure that this additional metadata can be collected at low cost to the public sector.

Also see: opendata.esd.org.uk which may help to unify data formats.

Rethinking how data is published
Public sector organisations need to move beyond issuing static one-off snapshots of geospatial data and issue more periodic updates and eventually stream changes continuously or offer API access.

Data is much more useful if it's available country wide so public sector organisations (in particular Local Authorities) should explore combining their data and publishing on central hubs as a single dataset. We envisage a similar mechanism to how local authority food hygiene rating data is combined online [1] and note that for geospatial data this is already occurring to some degree via GeoPlace (although not published).

[1] http://ratings.food.gov.uk/

Q10: What areas of the underpinning geospatial infrastructure such as positioning technologies, including GPS and indoor positioning systems, and geodetic networks and frameworks to support them, should we be prioritising the development of, in order to support the emerging requirements for geospatial data?

No comment provided.

Q11: What role should the private sector have in both the development and maintenance of the underpinning infrastructure and enhancing the UK's geospatial data assets?

Use of the private sector to develop the underpinning infrastructure and to enhance geospatial data assets should be considered on a case by case basis.

As noted in our answer to question 4, the Commission should ensure that public sector data passed to the private sector (and more broadly any project supported by taxpayers money) remains accessible under an open licence in situations. This includes both outsourcing of work and privatisation of public sector organisations.

Examples of where this has not been the case include the privatisation of Royal Mail and the use of infrastructure support service providers to maintain Local Authority street assets (street lighting, benches, etc). Both of these have led to less access to key geospatial data.

Private sector organisations that digitise historic datasets and maps should not be able to claim copyright on the digitised copies.

Q12. Do you face challenges when working with geospatial data from across the public sector? If so, what are they and how could value be better released? Are there any technical remedies or standards that could be adopted to improve the interoperability of geospatial data? Please provide supporting evidence of what these remedies could help to accomplish.

Licensing continues to be a major challenge that our users face. This is especially true of data created by public sector bodies who are signatories of the Public Sector Mapping Agreement. The mixed source of their data makes it more challenging to release open data and our members frequently find that local authorities are unwilling to spend the time to understand licensing. This complexity (both perceived and real) is used as a barrier to restrict the release of data.

Q13. How can the Geospatial Commission act as a more effective customer for geospatial data on behalf of the public sector?

The Geospatial Commission should ensure that geospatial data is free from restrictions particularly related to derivative works. Signatories of Public Sector Mapping Agreement, the PAF Public Sector Licence and/or the Aerial Photography Great Britain contract should be free to create derivative work and release this as open data.

Q14. Are there any additional geospatial datasets, from the other partner bodies or other sources, that the public sector would derive significant benefit from having access to, that might have novel and valuable use cases? What would that access look like?

The public sector should be encouraged to fully explore what data may be of interest to them in better delivering their services. This should not be limited to just the data of the other partner bodies or other public sector bodies. A full exploration of all data, including private sector data and VGI datasets (such as OpenStreetMap) should be undertaken. Stimulus funding should be provided to allow (and actively promote) innovation with the public sector.

Q15: How can we best develop a single UK strategy, ensuring alignment between the individual strategies across the UK while still allowing for regional variations?

No comment provided.

Q16: How can we best ensure effective local authority coordination and sharing of best practise, using location data to better deliver public services?

Coordination between Local Authorities is a topic we touched upon in our answer to question 9. Please see our answer to that question. Additionally, the Commission should support the concept of central hubs for combining datasets that are maintained by individual local authorities. Data is much more useful if it's available country wide in a single download/API. Food Hygiene Rating Scheme (FHRS) data is a good example of where this is happening already. Public Rights of Way is half-way there with the collation by GeoPlace; they just have to publish it!

To facilitate effective coordination Local Authorities must also be supported to engage in knowledge sharing forums, with stimulus funds available to further innovate and engage with the geospatial industry. Efforts should be backed up with engagement and promotion at a senior level to ensure that geospatial data and analysis is recognised as a high value asset to Local Authorities.

Q17: As a result of this analysis, we are prioritising the exploration of possible initiatives in the high-value categories identified:

- **property and land**
- **infrastructure and construction**
- **mobility**
- **natural resources**
- **sales and marketing**

What are the existing or potential geospatial applications which could be scaled-up or developed in order to capture economic value? (We would particularly welcome responses from industry and other bodies engaged in these sectors.)

The number of applications of geospatial data are limitless with existing applications representing just the start of the possible. The OpenStreetMap project has demonstrated how a crowd-source and collaborative approach can play a central role in the geospatial industry. Since its creation in 2004, OpenStreetMap has been creating and supporting jobs in the UK and globally.

Our members are ready to support the innovation and development of new geospatial applications. Many employees of the geospatial industry will have a direct or indirect experience of OpenStreetMap. We have recently started a UK Talent Directory for those who wish to work on projects that involve / incorporate OpenStreetMap. From teachers, to developers, to artists, we look forward to continuing to support existing and potential geospatial applications identified by this consultation.

Q18: Are there any other areas that we should look at as a priority?

No comment provided.

Q19: What are the main potential private and public sector innovations that will rely on the use of geospatial data to rollout, and are there corresponding regulatory challenges?

No comment provided.

Q20: How best can we make the UK's presence in the international geospatial world more visible?

The Geospatial Commission should consider where target funding can best be utilised to support the public, private and voluntary sectors on the global stage. Support of the academic and fledgling business community will help to keep the United Kingdom at the forefront of the international geospatial world. Opportunities to attend and present at global forums should be investigated. We should aspire to host global forums and be thought leaders at the cutting edge of the geospatial data industry.

Furthermore, the Geospatial Commission should be proud of the work delivered, not just by the public and (for-profit) private sector, but also the achievements of the volunteer and non-profit sector. They should champion this on the global stage to encourage inward investment and skill growth. Recognising the special economic circumstances of the volunteer and non-profit sector, the Commission should tailor solutions to ensure that all sectors (public, private, non-profit and voluntary) move forward together.

Q21: Where should the UK be looking for points of comparison overseas? Who are the other international exemplars? What best practice is being modelled overseas that we can learn from?

We believe that the global, open and collaborative nature of the OpenStreetMap project has a pivotal role to play in unlocking extra value for the economy every year. OpenStreetMap has grown to become one of the most successful collaboratively maintained open datasets in the world. This success has meant that OpenStreetMap has become part of the global geospatial data infrastructure and is supported by a rich ecosystem of individuals, community groups, small businesses and multinational organisations.

This page [1] sets out some examples of collaboration between the public sector and the OpenStreetMap project. The examples are global in reach and demonstrate the benefits of greater collaboration and openness.

The UK should be looking to be an international leader. OpenStreetMap Ireland have made us aware of a bad example from Ireland in the recent introduction of the Eircode (Postcode), where the data is proprietary, but individuals are only allowed five searches per day. It is also unclear how the information learned in those searches can be shared. During the debate prior to the introduction of Eircode the private ownership of the British postcode system was used as an international example for this policy. This highlights that, whilst it is always useful to look for points of comparison overseas, findings should be tested with the UK geospatial industry and that the UK should seek to raise the standard higher.

ORDNANCE SURVEY

Response to the Geospatial Commission National Geospatial Strategy – call for evidence

OFFICIAL

October 2018

Ordnance Survey

Contents

Ordnance Survey (OS) is the National Mapping Agency for Great Britain, and a world-leading geospatial data and technology organisation. As a reliable partner to government, business and citizens across Britain and the world, OS helps its customers in virtually all sectors improve quality of life. OS expertise and data supports efficient public services and infrastructure, new technologies in transport and communications, national security and emergency services and exploring the great outdoors. By being at the forefront of geospatial capability for more than 225 years, we've built a reputation as the world's most inspiring and trusted geospatial partner.

Introduction

Data is the fabric of the UK economy, and location data is the thread that ties it together.

Everything happens somewhere; location data – describing people, places, objects, or events – both underpins the economy and is a by-product of the number of new technologies connecting our streets, homes and businesses.

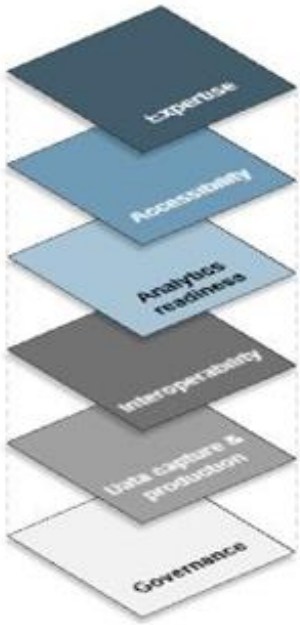
Location can also be the simplest unifying component, joining together multiple perspectives of the real world. Information about physical assets and people, historic and real time can be manipulated to determine problems and define and measure appropriate services.

Whether it is gathered by a surveyor using highly-accurate equipment on site, or crowd-sourced from millions of mobile phones, better use of location data could unlock £6-11bn of value for the UK economy.

Ordnance Survey (OS) is a global leader in the creation and maintenance of geospatial information, second only to the US in the World rankings in the GeoBuiz Report *Geospatial Industry Outlook & Readiness Index 2018*. We produce an authoritative, consistent register that captures all 243,241 sq. km of Great Britain to centimetre accuracy, forming a core data asset on which both the public and private sector rely.

Our response to the National Geospatial Strategy Call for Evidence draws on our 227-year history as the National Mapping Agency for Great Britain, as well as our experience working on today's cutting edge of data collection, curation and analytics. With over 400 commercial partners and more than 5000 users across the UK and internationally, we are working with the users and providers of geospatial data and services every day, responding to their requirements and changing to meet their future needs.

Unlocking the value of geospatial information will require investment and coordination across six distinct layers of the geospatial infrastructure. (LEK, 2018)



Description	Required improvements
• Specialist knowledge of how to apply and extract insight from GI	• Development of intellectual capital (e.g., into new areas such as machine learning) and more constructive advisory relationships with users (e.g., cultivating start-ups)
• Ease with which geospatial data can be accessed and shared	• Common licensing frameworks and access platforms (e.g., open APIs and simplified web access)
• Ease with which geospatial data can be deconstructed, scrutinised and analysed	• Re-structuring of data and metadata (e.g., providing platforms for analysis of geospatial data) and improving data currency
• Extent to which geospatial data is compatible with other data and systems	• Development of common standards and schema across geospatial domains (e.g., adoption of common geospatial identifiers)
• Capture, extraction and subsequent maintenance of geospatial data	• Higher volumes of data with more detailed features (e.g., street furniture, building attributes)
• Creation of geospatial policy and standards	• Greater engagement by all relevant stakeholders across government and UK plc (e.g., to make more government geospatial data openly available)

As the Geospatial Commission forms, it will need to make strategic decisions to relieve 'upstream' constraints – data, interoperability, analytic readiness – as well as targeted interventions in particular sectors and emerging markets to stimulate and promote 'downstream' use of geospatial data and to release the associated economic and social benefits.

We firmly believe in the need for ambitious National Geospatial Strategy, focused on the need for clear policy leadership, and prioritisation of demand and investment. The Commission will have to balance the need to serve today's users while fostering new technologies, emerging use cases for geospatial data, and our international position, to ensure that we are building the infrastructure to enable the fourth industrial revolution.

It is important to recognise that geospatial information is rarely the only answer – its real value emerges from the interoperability with different data sets. The same will stand for the National Geospatial Strategy. It will need to recognise the overlap of ambition and value with the other major government strategies – the Industrial Strategy, an emerging National Data Strategy, and others.

OS has the insight and experience to help inform a new National Geospatial Strategy on the role of location data in emerging use cases, including autonomous navigation, the Internet of Things and underground assets. The Commission may also have a role to play in helping focus cross-government efforts on Earth observation data. Any strategic investment and policy coordination should focus on meeting user needs with the right information at the right time, building a single chain of geospatial information which is fit for purpose.

We also recognise the value of a broader, needs-based focus for skills development in geospatial data and geography. Individuals who can use location effectively as one element of complex problem-solving will be highly-prized in a data-enabled economy. Our geospatial community in the UK is already one of the strongest in the world, and it is important that we recognise the value that geographic insight can bring to the wider data skills needed by the future economy.

OS stands ready to support the Commission, as a partner body and as the National Mapping Agency for Great Britain. As experts in our field, we are excited by the opportunity which location data brings in both the public and private sectors. The creation of a Geospatial Commission for the UK recognises the critical opportunity just ahead – the chance to foster the strongest, most connected digital economy in the world.

Our response references a number of supporting case studies which show how OS geospatial data is helping tackling cross-cutting challenges – please find these in *Appendix one*.

We have also included a list of suggestions for additional reading at *Appendix two*.

The Emerging UK Geospatial Strategy

Q1: Is our view of the geospatial data types accurate? If not, what should be included or excluded from this?

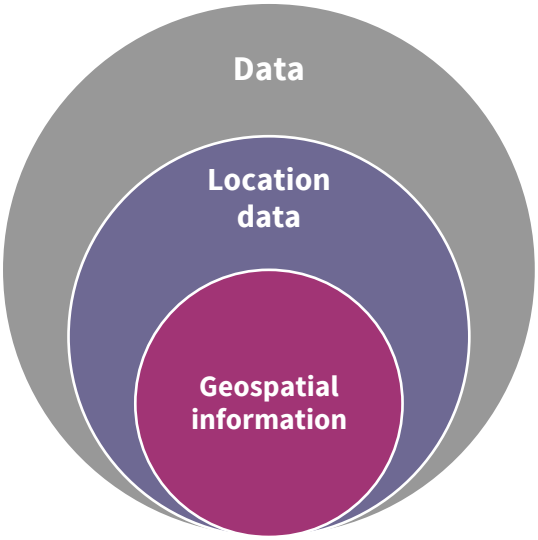
Regarding the first two definitions, OS notes that the distinction between geospatial data and positional data appears to relate to the *purpose* of the data. This is not intrinsic to the data itself (essentially both categories have a direct or indirect location, and a variable number of attributes). Data can have more than one purpose – intentional or not. Hence these two categories are not distinct and their potential use is not clear.

Geospatial data itself Is wider than place-based or topographic data and might include: subsurface geological layers; topological networks such as rivers and roads; or the shape of Earth's terrain.

The third definition of 'geospatial identifiers' can be determined, and we have no comment.

The fourth is a 'service' but speaks of insights and products. The distinction between this and the first two is also unclear.

If the Commission wishes to continue to use these terms, then some clear examples would assist understanding.



Although it is not stated as to the purpose of these categorisations, we note that for the purposes of the Commission, it may be useful to draw some form of sub-categories of geospatial data, whether that is for commissioning services, to establish the scope and remit of the Commission within Whitehall, or to create useful links with other policy areas.

To achieve this, we suggest that there are existing definitions which might assist. The International Standards Organisation (ISO) defines 'geographical data' and 'geographical information' in *http://www.isotc211.org/TC211_Multi-Lingual_Glossary-2016-06-28_Published.xls*. Although ISO uses the word 'geographical' rather than 'geospatial', these definitions are widely used and appropriate. Further categorisation will depend upon the Commission's objectives.

The UN has determined a 'minimum list' of fundamental geospatial data themes. See *http://ggim.un.org/meetings/GGIM-committee/8th-Session/documents/E-C20-2018-7-Add_1-Global-fundamental-geospatial-data-themes.pdf* for the list and short description of these themes.

Theme 1: Supporting innovation in the geospatial sector

Q2: In addition to current government policy, what are the areas of geospatial skills where the Commission could best focus to help ensure the necessary capability within the UK for the future?

There are also specific geospatial skills in which we recommend that the UK must *retain and enhance* capabilities. Our geospatial community in the UK is already one of the strongest in the world, and it is important that we continue to nurture these foundational skills to support our ambitions. The following are core to the continued delivery of user needs today:

- Geospatial Enterprise Systems
- Geodesy
- Global Navigation Satellite System (GNSS), Global Positioning System (GPS) and Geoids
- Earth observation
- Satellite and aerial imagery capture and processing
- Photogrammetry and land surveying, including: laser scanning, point clouds, and underground assets
- The collection, interpretation and management of crowdsourced data and Building Information Management (BIM), including data quality and provenance

The professionalisation of geospatial skills is important to ensure that practitioners are viewed on a similar level as their counterparts in, for example, the engineering field. Geoscience degrees deserve continued government support. Government has recently started to create a 'Geography' specialism, as part of the Government Science and Engineering Profession, which would benefit from the Commission's support.

But geospatial skills should be a specific component of a wider data and IT skills landscape, with a focus on data architecture, engineering, modelling, management and governance. Skills which enhance data standards and data quality, enable interoperability and security, and can create new software intellectual property will be critical. Examples include:

- Collaboration and linking of multiple technologies and data sources
- Data analytics skills, which are fundamental to the continued relevance of geospatial data; analytic and predictive modelling, scenario planning, risk and impact assessment, coupled with data science, machine learning and citizen science, increasingly important to enabling society to realise the full benefit of geospatial data
- Developer, software architecture and digital engineering, including data visualisation, augmented reality, gamification, are increasingly relevant alongside user experience design. These skills enable an accessible, real time, intuitive and scalable means of accessing, integrating and serving data
- Geographical understanding and interpretation of data to produce spatially coherent decisions
- Ensure the topic of data ethics thinking is included as a skill to build trust and upfront consideration of the use of the data.

Q3: What are the geospatial skills needs and gaps in your organisations, how can these be most effectively addressed, and how can careers in the sector be best promoted?

There is a challenge in recruiting on the data side for Data Architects/modellers, Data Management Specialist (Data standards, metadata, etc.) and IT development and engineering capabilities into OS as 'geo' can be viewed as a niche industry. To tackle this, we undertake a range of actions, outlined below, and supplement that programme by positioning our employer brand to emphasise the innovative digital nature of geospatial engineering.

Talent development programmes

OS has designed and runs its own IT Trainee programme so that we may more quickly contextualise engineering skills within a geospatial environment. While the languages we use, and to some extent operating environments, are not hugely different, their application in a geospatial context is more tailored. To support people as future 'data leaders', we use staff capability plans, individualised learning and development plans, which identify current skills necessary to deliver today's projects, and those skills which will be required in the future.

OS is continuing to grow its capability in data science and analytics. In previous years, we have invested in data science graduates. We note that data science and AI are increasingly coveted areas of expertise. Our learning from previous graduate schemes is that OS – and the wider geospatial sector – is generally not considered to be a career choice; students tend to be unaware of geospatial issues, unless they have previously studied subjects like Geography.

In 2018/19, OS is designing and trialling (with an internal talent pipeline) a multidisciplinary geospatial graduate development programme which will immerse graduates in all aspects of essential geospatial capabilities: core data collection and maintenance; developing technologies (e.g. machine learning, sensed data); data analytics and modelling; core engineering; technical consultancy; technical product/data ownership; and innovation. During this programme, individuals will also undertake modules and masterclasses in wider business skills, including: business modelling and planning, finance, stakeholder management and HR. The graduates we recruit over the course of this year will then participate in the above programme.

Skills development collaboration

The sector has fundamentally changed: we have had to invest time and effort to connect with the disciplines which have relevant capabilities, namely maths, physics, computer science, and data science. It is no longer as necessary as it once was to be a geographer or geospatial data expert. To support work which is already underway, the IT and geographical sectors should collaborate on large-scale campaigns to promote career opportunities in the geospatial sector to a broader range of disciplines.

OS continues to support education and research with teams working in collaboration with the education sector and spanning primary and secondary education through to Degree, Masters and PhD programmes along with Knowledge Partnerships in conjunction with a number of universities across the UK.

For examples of programmes where OS is working in partnership to broaden and enhance geospatial and related skills, we refer the Commission to:

- Royal Geographic Society (RGS) and the Association for Geographic Information (AGI): Young Careers Network. With the RGS we support geography teaching at all levels, and the Chartered Geography accreditation from the RGS/AGI.

- Digimap, an initiative providing access to a range of datasets for the purposes of education and research.
- Royal School of Military Survey (RSMS): the development of an MSc aimed at geospatial intelligence leaders, and senior, pan-government education/training facilities.
- Government Geography Profession, and Digital, Data and Technology Profession: development of geospatial skills competency frameworks. The Geography profession has recently been formed as a sub-profession of Government Science and Engineering. It aims to support practitioners in the profession with opportunities for secondments, career pathways, and mentoring.

We would welcome the opportunity to lead/support the creation and management of a broader and cross sector 'academy', developing the geospatial capability of the future for the UK in collaboration with other geospatial and public sector bodies, accelerators, and private sector partners. Organisations such as the Royal Institute for Chartered Surveyors (RICS) or the Institute for Civil Engineers (ICE) are critical for sharing best practice and encouraging access to geospatial skills and qualifications.

There is a further opportunity to widen the current apprenticeship schemes to a broader multidisciplinary approach, where core geospatial skills are married to business, technology, innovation and creative capabilities. EPSRC are currently considering a bid for a Geospatial Systems Centre for Doctoral Training to admit twenty PhD students per year over five years, which would be a significant investment in such training. OS are preparing to support a secondment into the Welsh government to

Q4: How should we prioritise which geospatial datasets we target to increase access? Please provide evidence of why this would be of value, and how access or quality could be improved?

A 'geospatial data infrastructure' can mean two things – it can mean, as in Q10 – the infrastructure required to support the collection, management and supply of geospatial data – this would include, for example, the infrastructure necessary to support the geodetic reference framework. The second meaning is the part of a wider data infrastructure which relates to geospatial data, such as those set out by the United Nations Fundamental Data themes.

Within the government sphere, OS continues to hold to the principle of clear separation of duties in creating and managing particular data registers – 'one data, one place, one authority'. The Commission is well-positioned to ensure complete coverage of geospatial data assets, and the necessary standards for linking, interoperability and accessibility.

From our experience, there are datasets which would benefit from improvements to their quality or greater accessibility. To mobilise the value in these datasets, it is imperative that the Commission, and ultimately those who will use those datasets, take a system-wide view about interoperability and standardisation. Doing this will lead to a far greater value proposition, and supports Government's initiatives under the Industrial Strategy, including the introduction of the Centre for Digital Built Britain.

- Local authority datasets

  These datasets, including those relating to local plans, public rights of way, planning applications and traffic restriction orders, all suffer from being inconsistent in terms of quality, completeness, format and availability. Improved data would significantly reduce the manual effort required in obtaining and processing datasets at a national level. The solution is likely to be a mix of mandated standards and

financial incentives for local authorities. Government could consider a national planning applications service to help streamline and standardise datasets, as well as improving the service to citizens.

- Community Risk Registers

  These Registers contain a wealth of valuable information for resilience planning. In our experience of recent exercises, these are often locked in documents and not readily useable by national agencies – this represents a serious risk.

- Valuation Office Authority (VOA) datasets

  These datasets contain of a wealth of information about building type, age and construction material which would be of great value to a wide range of users across public and private functions. At present, access to VOA data for residential properties is restricted by legislative order. This may require further consideration.

Encouraging a national register of datasets collected in the private sector would be a welcome development. This task would be made considerably easier if all geospatial datasets were defined and published in a way that makes them easy to find and use, e.g. Data.gov.uk.

- Utility datasets

  A lack of consistent information about the location of gas, water, electricity and telecommunications networks is problematic. Time-consuming efforts to identify and locate assets hampers construction projects, and increases the risk of striking buried assets. Many European countries are addressing this problem by mandating the publication of utility asset data through regulation.

  Please see the following case studies in *Appendix one* providing information on OS' recent work to support data collaboration over subsurface assets:

  - Project Iceberg: subsurface data collaboration
  - A prototype for combined data at the North East Underground Infrastructure Hub

- A definitive rail network

  This is not available in the UK, and is hindering efforts to develop fully integrated multi-modal mobility services.

- Location occupancy/footfall data from mobile phones

  This is an emerging class of data with significant potential to assist a range of public and commercial activities. At present, this type of data is immature and fragmented across several providers.

Data infrastructure

Data assets are only one aspect of this wider data infrastructure. A data infrastructure has several core elements, including standards and technology, legislation and regulation, and the institutional arrangements required to enable the interoperable use of data.

The United Nations is developing an Integrated Geospatial Information Framework[1] which would be an appropriate place to start in assessing where beneficial investments should be made. The component parts are:

[1] *http://ggim.un.org/meetings/GGIM-committee/8th-Session/documents/Part%201-IGIF-Overarching-Strategic-Framework-24July2018.pdf*

- Governance and Institutions
- Legal and Policy
- Financial
- Data
- Innovation
- Standards
- Partnerships
- Capacity and Education
- Communication and Engagement

A review and gap analysis against this framework would provide a comprehensive approach to developing an infrastructure rather than solely focusing on data assets.

A note on implementation…

Data usability and value issues extend beyond 'accessibility' and 'quality' and are significantly affected by financial incentives and business models. Producers and custodians of datasets require clear financial incentives to maintain data to a required specification and quality, which are themselves highly dependent on use-case. An example of this is PAS 256, a standard for the collection, recording, maintaining and sharing of information and data related to underground assets, which to date has had limited impact, partly due to a lack of incentivisation to share data which is fit for purpose.

Q5: Do you anticipate that any changes will be needed to both address data and the wider address ecosystem to support emerging technologies? Please provide evidence of value to support any proposed changes.

We recognise that the addressing conversation is a complex one. Geoplace came about as a result of a previous government's decision as a way to improve the address quality for Great Britain. The National Address Gazetteer has been recognised as the solution of choice for the public sector, and we are proud to support its work in partnership with the Local Government Association.

The Geospatial Commission has already committed to explore opportunities to open the key identifiers of UPRN and USRN. This is a positive step, as expanded use of UPRNs will help ensure that the addressing infrastructure is widely used and valued. We recognise that a single address registry is an ambition, as the value of common addressing presents the largest opportunity for public sector efficiency, but it would be necessary to unpick the political decision taken in 2011.

Linking to UPRN

The driving global trend is towards address 'currency'. For example, shorter address data life cycles for temporary structures and the greater linking of government data to UPRN.

Asset registers, including new ones, should be linked so that other permanent features (lamp posts, etc.) have a UPRN derivative.

Future use cases

Changes to address data are a subset of the Internet of Things and fine geography requirements. Delivery points are a single feature in a building, others include: smart meters, fire exits, telecommunications repeater stations, accessible toilets which will require classification, and exploitation to support the realisation of benefits from emergent technologies. There is an increasing need for rich geometry and attribution to be accessible via addresses.

OS would benefit from open and consistent address data from a change intelligence perspective. Local Land and Property Gazetteer (LLPG) and National Address Gazetteer (NAG) data has great potential if maintained in a consistent way, and with more mandatory fields. The same is true for the National Street Gazetteer (NSG).

At a granular level, and using OS as an example, change intelligence can be derived from NAG and NSG if maintained effectively with mandatory fields which would lead to better data currency and resilience. OS is perfectly positioned to not only take change intelligence feeds to enhance the currency and completeness of its data, but to link 3rd party datasets – including National Rail, BT and Post Offices – to OS maps, bringing consistency and improving interoperability (ref: National Location Framework). This also would lead to a better product and an improved OS offer.

The quality of outputs could be improved by sharing data access across the sector and cross-referencing with overlapping datasets. In time, this could be maintained automatically with improvements achieved from customer and user feedback.

Our work to deliver OS' Public Task has highlighted requirements for vernacular names to be included in OS data, in support of emergency services. This could include collating information from sources such as Fintan (HM Coastguard), the Mountain Rescue vernacular name database, and crowd-sourced third party data, e.g. yourPlaceNames[2]. This would enhance our offer towards a potential Emergency Services Gazetteer.

Q6: How should the Commission be looking to develop the UK's capability in Earth Observation data, both technologically and to support an effective market?

For the context of this response, OS defines Earth observation (EO) as satellite-derived data and information that can be obtained from a variety of sensors. We recognise that there are wider definitions of Earth observation, including in-situ or airborne observations, however these are out of scope for our response.

OS has been encouraged by the rapid development of EO-related technologies in recent years, including the leading role played by British companies in stimulating development and innovation. We have recognised the potential for satellite-derived EO data to detect topographic change, and to provide input into land cover and land use datasets. These changes are removing some of the barriers to adoption of EO by OS[3] into its internal processes and workflows. We believe EO can deliver:

- Operational efficiencies[4]: e.g. change detection (change driven topographic review process, increases currency while reducing detection time).
- New data outputs: e.g. variable land use classification; temporal variance (land use/cover change) and change notification (monitoring).

However, barriers to adoption of EO data remain in the wider market. One of the most significant barriers is the cost associated with the storage, management, and usability of EO data. The operational logistics regarding access to data and making it ready to use has increased as a direct result of the greater volume of data now available from multiple sources.

---

[2] *www.yourplacenames.com/vernacular/*

[3] *https://londoneconomics.co.uk/wp-content/uploads/2018/07/LE-IUK-Value-of-EO-to-UK-Government-FINAL-forWeb.pdf* (page 28)

[4] A practical example of this is OS's work with the with the Mohammed Bin Rashid Space Centre (MBRSC) in Dubai to automate the production of geospatial information *https://www.ordnancesurvey.co.uk/international/case-studies/dubai-auto-change-detection.html*

Technical barriers for use also exist for most potential users of EO. Data is often 'raw', as it is made available without the necessary processing operations (sometimes referred to as image restoration and rectification, intended to correct sensor- and platform-specific radiometric and geometric distortions of data) that are required to bring EO data to a usable level.

In isolation, EO data does not provide answers to many of the questions that potential uses are likely to be solving. Focus should be on turning EO into actionable (analytic ready) data by its integration with other data sources (such as land registration data, population statistics and topographic data such as DTM/DSM). We note the efforts being made by EuroGeographics, working with the European Economic Area, to facilitate the use of authoritative national reference data in the in-situ component of Copernicus.

"(Space Component) + (*in situ* Component) = Actionable Insights"

The Geospatial Commission could use its position at the centre of geospatial policy to address some of these issues, through working more closely with the technology lead on Earth observation (UK Space Agency) and the current centre of excellence (in Defra). A focus on user needs and potential applications of Earth observation, would help focus investment and coordination, cutting down on duplication and making more EO data useable at the point of access, referred to as Analytical Ready Data (ARD). This could include the provision of a national height model (DTM) to address geometric distortions would ensure consistency as well as alignment to in-situ (geospatial) data sets.

Similar approaches can be identified internationally. For example, Australia has been proactive in the promotion of their (Open) Data Cube technology, which is being used in a number of countries and regions (Digital Earth Africa). Implementation however could take many technological and commercial forms e.g. Google Earth Engine[5] and the GEOSS Portal[6], especially as the Data Cube concept is mainly focused on data curated over a long period of time, and at lower resolution.

It is important that the UK continues to benefit from the ESA's Sentinel data (Copernicus) and services, post the UK's exit from the EU. EO has an important role to play in supporting multiple Government Policy Departments[7], as well as the geospatial community more generally. In addition to working more closely with the UK Space Agency and Defra, the Commission could help provide support to non-departmental public bodies, such as OS, who are working with international forum (CEOS, GEO) through which the benefits of Copernicus data remaining free and open more generally can be articulated more effectively.

While Sentinel provides welcome data at a medium resolution, access to Very High Resolution (VHR) EO data is still prohibitively expensive for many potential users in the UK. Making this VHR data and other 'national coverage' geospatial datasets more readily available, or through developing UK systems that can deliver very high resolution EO data, would benefit many areas of society[8] including farmers, ecologists and the extractive industries. The current initiative by UK Space Agency to provide a national, VHR satellite imagery sample data set available to Government entities is a huge step in the right direction. We anticipate that the results of this trial will inform the thinking around the debate of the UK's national EO infrastructure offer.

Q7: Which new technologies should the Commission focus on to provide new opportunities to process and exploit geospatial data for economic growth?

The Commission is ideally positioned to invest and guide the development of a data infrastructure that is capable of making the most of emerging geospatial technologies to improve UK social and economic outcomes, using policies and investments targeted on high-quality, evidence-based approaches.

As with Earth observation, there is a risk that technologies are pursued for their own sake, rather than focusing on how they produce better outcomes for users.

OS has identified the following technologies as having significant potential for geospatial data to enable economic growth:

- Internet of Things
- Earth observation and sensing technologies from multiple platforms
- 5G and full fibre connectivity
- Connected and autonomous mobility, including vehicles and drones
- BIM
- AI, machine learning and automated decision-making
- Big data technologies (suitably extended to handle the unique properties of geospatial data)

Together, these technologies are empowering significant economic opportunities in the following markets:

- Intelligent mobility: Connected and autonomous transport, alongside electrification and vehicle sharing innovation, promises significant future social, environmental and economic benefits. OS is exploring this through its engagement in E-CAVE (Enabling Connected and Autonomous Vehicle Environments) and OmniCAV (testing Connected and Autonomous Vehicles) projects.
- Asset management: Geospatial frameworks can greatly enhance the value of asset data for whole-lifecycle and whole system optimisation rather than just e.g. construction or for individual networks. OS is exploring this through its engagement with the Centre for Digital Built Britain and the Digital Framework Task Group.
- Advanced connectivity: The deployment of full fibre and 5G technologies will be the focus of significant investment over the next decade; geospatial data will be vital in minimising the costs and risks and maximising the benefits of this investment. OS is exploring this through engagement with the DCMS and Bournemouth 5G project, and through participation in the 5G Innovation Network and urban and rural connected communities' projects. Please see *Appendix one*, *case study: OS innovation in Bournemouth to support 5G telecommunications infrastructure.*

  Additional policy benefits of advanced connectivity are referenced in the forthcoming White Paper, *Everything happens Somewhere* (November 2018).

- Smart Cities System infrastructure: Geospatial data will be central to applying system-of-systems projects for integrated management of Smart Cities. Please see *Appendix one*, case study: *Smart cities – the Manchester CityVerve project.*

In addition, the United Nations Group on Geospatial Information Management (GGIM) published a report on Future Trends in Geospatial Information Management in 2015. The report, produced by OS on behalf of UN

GGIM, recognises a number of broad trends in geospatial production and analysis which may be useful for the Commission.

All these new technologies will develop alongside AI and data trust capabilities. This increasingly networked data environment also exposes individuals and organisations to new questions of privacy, ethics, trust and security of data, particularly where multiple sources are conflated. Consideration of solutions to manage locational privacy and security is vital. Best practice is being created by the PETRAS (petrashub.org) research consortium.

Q8: How can geospatial data and applications be used to support enhanced roll-out of future technologies?

The core value of geospatial approaches is that location (three dimensions) and time (fourth dimension) represent a powerful means of authenticating multiple types of information and enabling interoperability between datasets, systems and domains.

In generic terms, geospatial data needs to have the following attributes to be able to support these technologies:

- Analytic-ready

  Increasingly, geospatial data needs to be consumed by machines and algorithms, and to support real-time data flows for simulation and prediction. This requires a shift away from cartographic-oriented models and formats, to more data-centric representations and compatibility with mainstream information standards. This requirement was demonstrated by OS' participation in the CityVerve project, which relied heavily on analytic-ready data (see *Appendix one*, case study on the CityVerve project)

- Interoperable

  Connected systems and devices increasingly demand interoperability. This is not just a question of data formats; it extends to ontologies and compatible definitions of the world and its features. This requirement was demonstrated by OS' participation in the ESPRESSO project, which developed a blueprint for cross-functional Smart City services.[9]

- Federated

  The future of geospatial data is to enable real-time connection and compatibility with external data sources, including volunteered (user generated) geographic information. This requirement was demonstrated by OS' involvement in the OGC Future Cities Pilot project, which demonstrated real-time data flows.

- Compatible with multi-media visualisation and consumption
  Data needs to be capable of being consumed in multiple ways, including visual, and rendered in dynamic and immersive environments on a variety of media and devices. This requirement was demonstrated by OS' participation in the CityVerve project, which presented the project outputs in a virtual reality environment (see *Appendix one* case study).

Potential technological innovations

[9] *https://www.ordnancesurvey.co.uk/about/news/2016/os-committed-to-european-smart-city-standards.html*

- The rollout of next-generation connectivity

  4G and 5G radio (potentially served through both cellular and satellite infrastructure), fast Wi-Fi and full fibre backhaul will provide the crucial environment for a wide range of future industries and public services. For example, blue-light services collaboration could be enhanced through apps which offer insight exchange, real time data flows and common operating pictures. Key regulatory challenges are:
  - To ensure sufficient service provision to more remote and less lucrative areas
  - To support the update and sharing of data about key infrastructure assets, such as lamp posts, for efficient service deployment. OS has explored this as part of the DCMS Bournemouth project – see *Appendix one*, case study.

- The realisation of Connected and Autonomous Vehicles (CAVs)

  Geospatial data is a key component of intelligent mobility. CAVs, electric vehicles and new shared ownership models are likely to have a profound long-term effect on travel behaviour, and ultimately the geography of Britain, with reduced space requirements for vehicles in both residential and business areas. This innovation will require a host of regulatory and public sector interventions to ensure beneficial public good outcomes (for instance, relating to safety, accessibility, congestion and air quality) particularly in considering the impact of the interaction of multiple CAVs in dense environments.
  In 2017, OS was awarded funding for the E-CAVE project (Enabling Connected and Autonomous Vehicle Environments), as part of the Industrial Strategy Challenge Fund. The objective of the project was to design the neutral frameworks, data and resources for CAV data exchange. E-CAVE will enable real-time vehicle-to-vehicle and vehicle-to-infrastructure data sharing, using open standards and architecture. The project focuses on positioning and safety, underpinned by geospatial technologies and standards. OS is working closely with industrial and academic partners, and the government-funded CAV Test Beds to accelerate the UK's CAV testing capability and develop new business models which exploit the value of CAV data exchange.

- The development of a National Digital Twin

  A 'digital twin' is a realistic digital representation of something physical. In this context, it is a digital representation of assets, processes or systems in the built or natural environment. What distinguishes a digital twin from any other digital model is that a digital twin attempts to represent reality accurately, in contrast to some models that intentionally simplify it. Visualisation makes digital twins look real, but it is the quality of the data on which they are based and the code at the heart of the model that makes them realistic representations of reality. See *Appendix one*, *case study: The benefits of a digital twin approach* for more information.

  A National Digital Twin is the prime focus of the Digital Framework Task Group (DFTG), established as a result of the publication of the National Infrastructure Commission's *Data for the public good* report.[10] A National Digital Twin is intended to be a federated environment showing multiple representations of the UK's economic, social and ecological infrastructure; a centrepiece of Britain's digital capability, enabling improved scenario planning, operational monitoring and reporting in a system-of-systems approach.

  The right application of high-quality integrated geospatial data offers the UK an opportunity to better plan and maintain energy and utility infrastructure, essential in the delivery of future technologies. An upcoming OS whitepaper *Everything happens somewhere* (Nov 2018) addresses the potential risks and opportunities for geospatial data to enhance UK energy infrastructure.

[10] *www.nic.org.uk/wp-content/uploads/Data-for-the-Public-Good-NIC-Report.pdf*

Theme 2: Enhancing the UK's geospatial assets

Q9: What are the options for how public sector organisations could continue to invest in maintaining and enhancing our geospatial data assets?

UK geospatial data infrastructure

As noted above a 'geospatial data infrastructure' can mean two things – it can mean, as in Q10 – the infrastructure required to support the collection, management and supply of geospatial data – this would include, for example, the infrastructure necessary to support the geodetic reference framework. The second meaning is the part of a wider data infrastructure which relates to geospatial data. Data assets are one aspect of this wider data infrastructure. 'Data infrastructure' has also been defined in several ways, but the majority of definitions identify the core elements as being the data assets, standards and technology, legislation and regulation, and institutional arrangements required to enable the interoperable use of data.

In accordance with our Public Task as the National Mapping Agency for Great Britain, OS must continue to maintain and enhance Great Britain's geospatial data assets. To do this, we must continue to invest in and enhance our infrastructure. The data infrastructure we require includes the data assets, technology and development of standards and data sharing arrangements, within an enabling national regulatory system. All aspects of the infrastructure should be considered and not just the data assets.

As part of the UK Location Programme driven by *Place Matters: The Location Strategy for the UK* (2008), a considerable amount of effort was put in between 2008-2012 to the creation of the UK Location Information Infrastructure (UKLII). There are lessons to be learned from this period: a clear central mandate, investment and coordination across the Devolved Administrations and local government are required if a UK strategy is to succeed. The initial implementation of the INSPIRE Directive provided much of the impetus for the UKLII.

Physical and system infrastructure

OS must continuously improve its physical and system infrastructure to deliver against our Public Task. This includes investment in OS Net – see *Appendix one*, case study: *OS Net – a fundamental geospatial asset* for more information.

In a data-rich world, OS will continue to increase accuracy, data resolution, securing continuity of supply and frequency of updates, as these are key to good quality services, as well as maintaining trust and confidence in the data. OS will continue to support the specific needs of Government through our agreed Mapping Agreements with Government and Devolved Administrations. OS would welcome the opportunity to undertake product co-development with Government, ensuring that delivery takes into account wider or alternative use cases, in order to maximise the benefits of the investment.

The United Nations is developing an Integrated Geospatial Information Framework[11] which would be an appropriate place to start in assessing where beneficial investments should be made.

[11] *http://ggim.un.org/meetings/GGIM-committee/8th-Session/documents/Part%201-IGIF-Overarching-Strategic-Framework-24July2018.pdf*

The component parts are:

- Governance and Institutions
- Legal and Policy
- Financial
- Data
- Innovation
- Standards
- Partnerships
- Capacity and Education
- Communication and Engagement

A review and gap analysis against this Framework would provide a comprehensive approach to developing an infrastructure rather than solely focusing on data assets.

Investment in data infrastructure

OS is continuing to invest in data infrastructure. We are investing in making our content accessible, discoverable, useable and consistent in terms of being up-to-date, using a consistent language, and enabling customers to easily associate their data to multiple views/content. See *Appendix one*, *case study: responding to customer requirements with the Open Zoomstack trial*

The recently announced 'unlock' projects, to be delivered in partnership with the Geo6, are a step toward improving outcomes.

Further opportunities for the Geo6:

- Building on recent successes, it may be that Joint User Groups are considered across the Geo6, with a single point of contact within each member organisation
- Taking a collaborative approach to research and innovation to unlock opportunities from a potential single geospatial asset, but which also accepts the limitations on OS arising from open data arrangements and commerciality
- Streamlining data exchange/delivery mechanisms, perhaps a single data/API portal, in order to increase efficiency

Commercial models

As a Government Company, OS is exploring new models to make its data products more commercially fit for purpose. We are developing enhancements around sensed data, systems of reference, and geo-production, and are looking to take advantage of the opportunities presented by AI and the use of multiple sensors. Greater automation in data collection would lead to lower cost and more up-to-date data. We will continue to develop closer relationship with our customers, and harness the opportunities offered by their feedback.

OS is also investing in Geovation, the hub for property and land innovation, supporting business start-ups to grow and succeed. See *Appendix one*, *case study: Geovation*

Q10: What areas of the underpinning geospatial infrastructure such as positioning technologies (including GPS and indoor positioning systems) and geodetic networks and frameworks to support them should we prioritise the development of to support the emerging requirements for geospatial data?

All positioning and mapping must take place on a mathematically simplified model of the surface of the Earth - from positioning within watches, to surveys for civil engineering projects and land administration. A robustly defined and accessible national geodetic framework is fundamental to link together all types of spatially referenced data. There is a fundamental role for government to maintain and develop the benefits and outcomes from this framework.

The 2015 United Nations Resolution entitled *A global geodetic reference frame for sustainable development* laid down the purposes and principles for the creation of an underpinning geospatial infrastructure. This encouraged Member States to enhance global cooperation in providing technical assistance, urged the implementation of open sharing of geodetic data, invited commitment to improve and maintain appropriate national geodetic infrastructure and multilateral cooperation.

There are a number of key elements of this infrastructure spread throughout Government, for example: British Geological Survey (BGS), OS, the Natural Environment Research Council and the National Oceanography Centre.

To meet emerging requirements, some areas for development are:

- To ensure that we have well-defined frameworks and systems that enable the integration of the outside, with the internal building view, alongside the assets that sit underground, linking together multiple positioning techniques.
- To better utilise the existing underpinning geospatial infrastructure more, for example the GNSS network (OS Net) to help understand the impact of interference on GPS users, especially in the field of critical national infrastructure (as described in the Government Office for Science's *Satellite-derived Time and Position: A Study of Critical Dependencies* review[12]). Please see the *Appendix one* case study: *OS Net*, for more information.

Q11: What role should the private sector have in both the development and maintenance of the underpinning infrastructure and enhancing the UK's geospatial data assets?

The private sector has a role in both supply and demand for geospatial information across the UK economy. OS operates on a partner model with over 400 commercial organisations who create products, applications, and services using our data, responding to user requirements or adding analytic services on top of what we make available in agile, responsive way.

We also recognise the value of a strong voice for geospatial industries from the Association for Geographic Information (AGI) to help raise and influence shared issues across the 'geo' sector.

[12]*https://assets.publishing.service.gov.uk/government/uploads/system/uploads/attachment_data/file/676675/satellite-derived-time-and-position-blackett-review.pdf*

In our experience, most private sector partners, regardless of market sector, are reliant on a consistent, trusted reference framework for geospatial applications. The public sector, without commercial bias, is trusted to provide an authoritative, 'single version of the truth'. That enables critical national infrastructure and services and the inter-operation of data and benefits to be derived.

However, while many private sector partners excel at innovation within a framework, the utilities are an example where no standard or framework for geospatial data exists. The issues of sharing data across the energy and utility infrastructures has emerges as a perennial problem for both street works and infrastructure planning. The Government can play a role in defining the expectations and boundaries for commercial activity, and even act as a trusted broker (see *Appendix one* case studies relating to Northumbrian Water and Project Iceberg) while leaving room for innovation and investment by the private sector.

One example of excellent collaboration is the ICE's Project 13, where the engineering firms are tackling challenges around digital assets for major infrastructure and construction projects to anticipate and drive best practice for major projects. Industry, in this instance, is aligning itself to government policy objectives, as government acts as a major commissioning/procurement body.

There may also be a role for private sector to provide better access to third-party data which could enrich the UK's national geospatial assets. The exponential growth in data sources and sensors over the last ten years, could form a critical flow of real time geospatial information into a digital twin. Government should still hold a reference set for this data and may need to tackle issues of privacy and veracity as the data is shared, but third-party data should be complementary, not competing with the reference data, as it serves a very different purpose.

Q12: Do you face challenges when working with geospatial data from across the public sector? If so, what are they, and how could value be better released? Are there any technical remedies or standards that could be adopted to improve the interoperability of geospatial data? Please provide supporting evidence of what these remedies could help to accomplish.

Through the delivery of the Public Sector Mapping Agreement, OS works daily with more than 5000 public sector users of its geospatial information. That experience of directly working with users, as well as our research into the next generation of public sector requirements, means that the OS has a unique insight into the challenges that emerge from trying to overlap and interoperate with public sector data.

Some of the more significant challenges in working with data from across the public sector include:

- Uncertainty over what the commercial arrangements are for a dataset
- Legal and regulatory barriers
- Cultural barriers e.g. the concerns of others about sharing data
- Knowing what datasets are available (and their currency and quality)
- An array of individual licensing agreements including data that is badged as open data but has restrictions on use
- Lack of interoperability between datasets
- No feedback mechanism on issues found with the data
- No guarantee that feedback will be acted upon when a mechanism is identified

- Different business drivers behind every organisation. For some, the data is what they are there to produce, for others it is a by-product. This impacts on the importance that they place on their data and how much effort they are prepared to spend on fixing and maintaining it

Integration of third-party data – a Digital Land Review 'unlock'

OS has found it challenging to access publicly-held geospatial datasets to support the development of new and existing data capture requirements. To support this, OS has created a data catalogue of third-party datasets. Poor quality and incomplete data mean that third party data are not always viable alternatives to in-house production methods such as those used by OS. For example, local authorities collect and maintain highways data in numerous different systems and formats. The ability to incorporate geospatial datasets could be improved by introducing royalty agreements into OS products and increasing collaboration between all suppliers of geospatial data.
Potential remedies are:

- Harmonisation of standards and licence information
  We know from INSPIRE that standards imposed from the top can be clunky. Data must be accessible and useable. Government could intervene when there is no motivation to standardise, or resource to do so. It would be good to see an agreement/alignment on standards and licence information to make it explicit, correct, and preferably machine-readable to facilitate sharing and exploitation. The official British Standards Institution committee for geographic information (known as BSI IST/36) already has this as part of its mission – perhaps this could be a useful body to help drive this forward.[13]

- Focus on interoperability
  Government could usefully intervene to make data interoperable, and linked to UPRN. A good starting point would be to streamline the local authority and national planning system through digitisation. Working with these data outputs is time-consuming and costly. A national planning portal could revolutionise the planning process and allow many other organisations to place their data in the solution. It should be possible to see existing data, the proposed planning area, the utilities, land ownership etc. all in one place. New Burdens funding may be required to progress this.

Q13: How can the Geospatial Commission act as a more effective customer for geospatial data on behalf of the public sector?

A relationship with business

The Geospatial Commission could usefully support public-private partnerships with both large corporations and small and medium enterprises. Considerable value could be gained from working with private sector companies to share geospatial change intelligence data. The tracking of land use change could also support housing development and help local communities to thrive.

Focus on customer needs and requirements

The Commission could usefully give data producers the space to work with, and closer to, their customers. OS would welcome the opportunity to share its work on user requirements with the Commission. Actions which help the sector to collaborate and share best practice would be welcome.

[13] *https://www.agi.org.uk/agi-groups/standards-committee*

Guide geospatial expertise into Whitehall

The Commission could look to fund geospatial subject matter experts (including those who work for data asset owners) into key Government Policy Departments. This could help improve awareness of the value of geospatial data, and provide a bridge between those Departments and the Geo6, ONS and other data providers.

Q14: Are there any additional geospatial datasets, from the other Partner Bodies or other sources that the public sector would derive significant benefit from having access to, that might have novel and valuable use cases? What would that access look like?

Please refer to our response to Q4 setting out our views on priority themes and datasets.

Q15: How can we best develop a single UK strategy, ensuring alignment between the individual strategies across the UK while still allowing for national variations?

The Geospatial Commission has an opportunity to write a policy-based, outcomes-focused National Geospatial Strategy, which is both clear about what success looks like for the UK, and well joined up with current Government strategies, including: Industrial Strategy, National Data Strategy and Transformation Strategy. The Commission should commit to consultation on the draft Strategy to allow for the identification of gaps or points of diversion with existing strategies. It would be a missed opportunity if the strategy were merely a series of discrete projects.

Strategic alignment across the UK will be a challenging task; some policy areas which use geospatial data, such as environmental policy, are matters within the jurisdiction of Devolved Administrations. That said, a single UK strategy can recognise that areas of the UK have distinct areas of specialism. For example, Scotland is particularly strong in coastal and rural geospatial expertise – see *Appendix one*, *case study: OS data being used to predict coastal change in Scotland*. A successful UK-wide strategy should draw on these areas of strength and encourage the sharing of best practice.

Experience from the UK Location Strategy would indicate that a common acceptance of the need for, and benefit of, a common data infrastructure is required in order to bring together the parts of the UK. In 2008 it was the common need to implement the INSPIRE legislation which drew together the Devolved Administrations. This requirement still exists and will continue to do so post-Brexit. Infrastructure development is an area which will span each individual strategy, although its implementation, and application may be a devolved issue. An appropriate framework to support and facilitate coordination across the UK would be the national approach to implementing the UN's Sustainable Development Goals. There are common data requirements across the UK not just for the measuring and monitoring of these goals, but also the programmes of actions required to achieve them. A clear line of sight can be shown between global strategy, national direction and local action.

Q16: How can we best ensure effective local authority co-ordination and sharing of best practise, using location data to better deliver public services?

We would suggest that local authorities are already coordinating activity and sharing best practice.

An effective model for sharing and best practice needs to deliver benefits for all those contributing to it; 'one way' relationships will not be effective in times of reducing budgets and higher workloads. In addition, the

right environment must be created for this to take place, an environment that provides support, sharing capabilities, recognition of success and incentives for continual improvement.

One approach to achieving this can be to use effective existing models. For example, having a centralised, detached organisation responsible for coordinating information-sharing to deliver a particular function. In 2010, following a consultation, the Department for Communities and Local Government recommended that a joint venture be set up between OS and the Local Government Association to create a new single source of address data. Today GeoPlace maintains the NAG that supports the needs of both the public sector and a wider commercial market and ensures effective local authority coordination and sharing of best practise. A consistent 'AddressBase', free to all public services, was seen as vital to deliver essential services to UK citizens, right through from ensuring benefit payments are going to the right place through to arranging school buses effectively.

In addition, working groups made up of those with common interests/challenges have also proven effective. For example, we have instigated a new working group called Government Address Interest Network which brings together cross-government teams to learn from each other's' experience of implementing authoritative address data. This information-sharing has delivered business efficiency outcomes in departments like HMRC and in the Health sector.

A 'Centre for Geospatial Excellence' might be part of the answer to effective local authority coordination, responsible for building capacity and best practice across local authorities and government Departments/delivery agencies. The Commission should look at the Scottish Spatial Hub[14] and the Scottish Local Authority Improvement Service as positive examples of improving outcomes at the local authority level.

Incentivising and recognising hard work and innovation through awards, and bringing together regional groups so users can support each other, help to break down silos and encourage collaborative working.

Combining datasets

Data that provides information on the built environment such as Valuation Office Agency, NAG, Building Control and the NSG play a crucial role in creating a digital view of the world. This information could be opened up to the geospatial community as a combined suite of material. A combined view of these datasets could, for example, assist utility companies to plan and maintain their geospatial information and assets.

OS spends time and effort 'mining' numerous data sources to fill intelligence gaps related to the NAG and NSG. Effective shared software tools would help local authorities, for example, to capture and maintain change more effectively and in a controlled environment. If this is done against a live OS data view, inconsistencies could be highlighted and corrected.

[14] *https://www.spatialhub.scot/*

Theme 3: Driving investment and productivity in geospatial applications

Q17: As a result of this analysis, we are prioritising the exploration of possible initiatives in the high-value categories identified:

- property and land
- infrastructure and construction
- mobility
- natural resources
- sales and marketing

What are the existing or potential geospatial applications which could be scaled-up or developed in order to capture economic value (we would particularly welcome responses from industry and other bodies engaged in these sectors)?

OS agrees with these high-value categories.

For more information about how OS is supporting the property and land sector, please see *Appendix one*, *case study: OS data supporting the property and land sector*.

Q18: Are there any other areas that we should look at as a priority?

Other areas of focus could include:

- defence and security
- environment and agriculture
- national resilience and predicting/reducing the impact of natural disasters
- sustainable energy, supporting the Government's clean growth strategies, and a fundamental enabler of infrastructure and mobility categories
- tourism
- Public Health, including supporting Government's priority to improve mental health by promoting access to, and information about access to greenspaces and greenways
- financial services – *please see case study: OS data supporting financial services markets*

Q19: What are the main potential private and public sector innovations that will rely on the use of geospatial data to roll out, and are there corresponding regulatory challenges?

Please refer to our responses to questions seven and eight regarding innovations which are likely to require geospatial data to roll out.

In addition to the regulatory challenges relating to privacy, drones and CAVs as set out in the Call for Evidence, the Commission may also wish to consider issues arising from:

- grid-stability and cyber-security
- consumer protection
- competition and intellectual property
- outcomes from the June 2018 Centre for Data Ethics and Innovation consultation[15]
- the roll out of BIM in both the public and private sectors
- the need to license historical data and imagery

Q20: How best can we make the UK's presence in the international geospatial world more visible?

UK Geospatial agencies such as UKHO, OS, Met Office and BGS have excellent reputations overseas, but this recognition and desire by other nations to learn from UK geospatial organisations is under-recognised by UK Government. In OS' case, this global reputation is in part derived from: the past contribution made by OS to the mapping of many nations; our thought leadership contribution to international bodies and debate; delivering success and profit to the UK; and our innovation in data, services and national geospatial enablement.

National geospatial information capabilities vary across the world, from non-maintained 1970s paper (or scanned) maps, to nations that embrace geospatial within government digital policies and strategies. Equally varied in delivery capabilities are land tenure and the poorly-defined concept of 'Smart' and how it is enabled by geospatial data. OS and the Geo6 have a clear part to play in helping other nations through long term commercial, and UK Government Overseas Development Agency (ODA)-funded, partnerships.

Departments and businesses that embrace geospatial information in the UK are more likely to do so overseas. By being 'an exemplar' in the use of geospatial to improve government effectiveness and efficiency, business growth and consumer lives, the UK can build on its current global position, particularly by utilising Government's overseas agendas.

Competition should be recognised:

- USA leads geospatial industries, and invariably partnerships will be essential with these global players. The UK is strong but will need to fight to retain its position.
- Other nations, such as Korea, Canada, and China, and global businesses have major international aspirations in geospatial information and land tenure, often including national agencies. Many nations promote geospatial industries overseas ambitions through state funded ODA (e.g. Japan and Korea). This may give them an economic advantage.
- In some places Open Street Map, enabled by large corporations, is standing in for national mapping.

[15] *https://www.gov.uk/government/consultations/consultation-on-the-centre-for-data-ethics-and-innovation/centre-for-data-ethics-and-innovation-consultation*

Understand and promote UK geospatial capabilities overseas

The UK aspires to be a leading digital nation and is highly regarded for its efforts to make data accessible for social, economic and environmental benefit. Geospatial infrastructure, data and services are a fundamental component of a national information infrastructure, and are the foundation to enabling location to be a central means to understand, analyse, make evidence-based decisions, deliver programmes, projects and services, and measure the achievement of policy goals.

For UK geospatial, location services and data analytics companies to succeed internationally, a UK Geospatial strategy should stress globally accepted underpinning frameworks, such as standards.

Innovation and education

The Science and Innovation Network, Innovate UK and others play a major role in the UK, but also internationally – from co-funded programmes to a growing network of DCMS technology hubs. Geospatial programmes do not overtly feature, but could. Bilateral international geospatial Research and Development programmes would help the UK's presence internationally.

Other nations (e.g. Singapore, Western Australia) have created geospatial incubators to help start-ups and small businesses; consideration should be given to leading, promoting and supporting a network of such incubators as a means of enabling UK start-ups to link globally.

Nottingham University has campuses in China and Malaysia offering geospatial education, but the biggest University provider of geospatial education globally appears to be ITC in the Netherlands.[16] Many geospatial leaders globally have had an element of education in the UK, Europe or USA, and often reference it favourably. Promoting greater access to UK geospatial courses may help build these long-term relationships.

Government overseas (trade) strategies

Consideration of geospatial industry at all levels within the Department for International Trade (DIT), and its global promotion, is a natural step. This needs to be consistent with efforts on behalf of the UK digital industries internationally.

Promotion of the UK's data capabilities within trade priorities will therefore benefit the UK's geospatial agencies and industry. This can manifest itself through:

- DIT's efforts in particular, through Department, National and regional strategies such as the FCOs Gulf Strategy and DfID's *Digital Strategy 2018-2020: Doing Development in a Digital World*
- senior trade missions and briefing inward visits to UK
- government measures focussed on policy outcomes enabled by geospatial data, rather than data provision alone

Recognising a select number of key sectors and focussing on incorporating geospatial information into their international trade approaches would be logical. Those sectors might include: infrastructure, telecommunications, extractives, agriculture, defence/security/resilience, and transport.

Official Development Assistance

UK has contributed significantly to global mapping coverage since the Second World War, largely through the government funded programmes of the Directorate of Overseas Survey, that merged into OS in 1984.

[16] *www.itc.nl/*

Sadly, many nations national geospatial coverage dates back to this era. In March, Ghana's vice president stated that it was not acceptable that the Ghanaian national basemap had not been revised since 1974 and subsequently launched a procurement process for an updated national basemap. OS played an important role in this decision by Ghana.

UK ODA objectives include:

- strengthening global peace, security and governance
- strengthening resilience and response to crisis
- promoting global prosperity
- tackling extreme poverty and helping the world's most vulnerable
- delivering value for money

All of these benefit from geospatial information, including land tenure and capabilities, just as they do in the UK. However, ODA departments rarely consider geospatial programmes as an investment in their own right. This needs to be urgently addressed.

The United Nations Integrated Geospatial Information Framework, with its significant OS strategic and editorial involvement, is being utilised internationally, particularly in developing nations. Recognising and supporting this framework in relevant UK international activities and strategies would help its adoption and also assist UK ODA considerations.

In the Department for International Development's *Digital Strategy 2018-2020: Doing Development in a Digital World*, Rt Hon Penny Mordaunt MP, Secretary of State for International Development, states: "We will work openly and collaboratively with others who share our digital vision; for a world where digital technology will be accessible to all, and where no one will be left behind."[17] Digital technology requires data, and in particular geospatial data. Yet most nations that the UK Government supports through ODA have little trusted and accessible geospatial data, nor effective institutions to create and maintain it.

It is not sufficient to collect data project by project. The UK should work in partnership with developing nations to build sustainable national government data institutions such as statistics and national geospatial agencies as a matter of priority.

Equally, open data principles should apply in ODA project delivery, and often does. Geospatial data collected as an element of project delivery has a far wider remit than for that single project, and its management and release should be sought in such projects, adding significantly to the value of UK investment.

Ordnance Survey supporting UK objectives overseas

OS aspires to be recognised internationally as the world's most trusted and inspiring geospatial partner. OS works with industry partners to deliver international commercial offerings and projects.

Achieving OS' international engagement goals manifests itself in a number of ways including:

- Support for United Nations activity to meet the UN *Transforming our World: 2030 Agenda for Sustainable Development*.[18] There is a clear requirement for geospatial thinking and data in the achievement of all associated Sustainable Development Goals. This also applies to agreements such as the Sendai

[17] *https://www.gov.uk/government/publications/dfid-digital-strategy-2018-to-2020-doing-development-in-a-digital-world*

[18] *https://sustainabledevelopment.un.org/post2015/transformingourworld/publication*

Framework for Disaster Risk Reduction 2015–2030, the United Nations Framework Convention on Climate Change (Paris Agreement) and on the United Nations Ocean Conference: Call for Action. The UK is already active at this strategic global level through the UN Committee of Experts on Global Geospatial Information Management (UN-GGIM): at a national level, directing activity and monitoring progress through ONS and relevant Government Policy Departments and Devolved Administrations; and at a local level, taking action in both the public and private sectors.

- Support for the Open Geospatial Consortium, influencing and bringing learning back into OS in equal measure.
- A current secondment to the Group on Earth Observation (see case study in reference to Q.6) related to work on EO and disasters.
- Providing senior subject matter expertise into governments globally, some of which may lead to downstream opportunities for OS and other UK companies
- Hosting the Cambridge Conference, the quadrennial meeting of global national geospatial agency leaders that has been running since 1928. In 2020 this will be run back-to-back with the UK hosted United Nations High Level Forum on Global Geospatial Information Management, the first such event in Europe

A clear line of sight can be shown between global strategy, national direction and local action which could be an exemplar internationally.

Q21: Where should the UK be looking for points of comparison overseas? Who are the other international exemplars? What best practice is being modelled overseas that we can learn from?

There is no direct comparison of our geospatial ecosystem with other countries.

The legal, regulatory, policy, and institutional context varies, along with the social, economic and environmental challenges, the geography of the country and the maturity of the geospatial industry. However, certain aspects can be explored in other countries to identify potential good practice which could be tested in our context.

Examples of overseas points of comparison include:

Pathway	Nations which could be considered for comparison	Learning point from practice modelled overseas
Governance and institutions	Abu Dhabi	ADSIC approach to facilitating an SDI and a geospatial community.
	Sweden; Lithuania	Holistic land administration and land governance; State Enterprise Center of Registers (one agency responsible for several key registers).
	USA	USA is considered strong in certain areas, its Federal Geospatial Data Committee and its potential Geospatial Data Act amongst them.

Pathway	Nations which could be considered for comparison	Learning point from practice modelled overseas
	Australia	Governance Framework for the Digital Built Environment *https://docs.wixstatic.com/ugd/800d93_d9423643750744d8aac5347d7c6004b6.pdf*
	Netherlands	Netherlands has created an oversight body for their geospatial infrastructure called Geonovum. See *https://www.geonovum.nl/*
Policy, strategy and legal	Oman	Trying to introduce and impose geo data/survey/map policy.
	Estonia	e-legislation.
	South Korea	Successful nationwide planning and roll-out of 3G network. UK could learn from this for its fibre/5G roll-out programme.
	United Nations	Integrated Geospatial Information Framework and Future Trends Documents.
	Australia	Geosciences Australia. Long term contracts to ensure government and industry invest in new capabilities with assurance of supply.
Financial	Singapore	Central funding for Virtual Singapore initiative and platform. Significant capital investment (The project was initiated at a cost of $73 million for the development of the platform as well as research into latest technologies and advanced tools over a period of five years).
	Netherlands	Self-financing: Government compensation for opening up geospatial data.
	Denmark	Investment in geospatial information predicated on the impact (savings) across government.
	Australia	Australian (MOD) GEOINT Organisation audit of all projects to determine future needs for GI and the removal of barriers to use. Includes 'data' sign off at gateways to ensure data aspects have been considered.
Data	Ireland	Integration of statistics and geospatial; data for national decision-making.
	Singapore	Virtual Singapore initiative and platform, 3D virtual model/digital twin of Singapore.
	Netherlands	Integrated approach to national mapping and built environment data, including high quality 3D city data models.
	Australia	Acceptance that time (4D) is an essential component of geodata as governments adopt digital twin approaches.

Pathway	Nations which could be considered for comparison	Learning point from practice modelled overseas
		Authorised, federated, fully interoperable, 3D datasets enabling users to model the Natural and Built Environment across Australia and New Zealand *https://www.vanzi.com.au/* NSW: Data recognised as an asset under state infrastructure strategy.
	Mexico	Mexico has a merged geospatial and statistics organisation.
	Israel	Tel Aviv approach to smart city based upon improving services to citizens.
Services	Dubai	Dubai has included spatial data as critical data and made policy that it be included on their data registers (just like other data e.g. statistical) within the Dubai Data Establishment.
	Netherlands	Kadaster services.
	Singapore	Services built on the Virtual Singapore platform to support experimentation, virtual test-bedding, planning and decision-making.
Innovation	Dubai	Dubai recognises the benefits of integrating geo data/tech with other areas to make superior services e.g. linking payment + ID + location together to monitor movement of people and funds.
	Taiwan	GeoSMS and Resilience services.
	Sweden	Blockchain, 3D, GIS/BIM.
	USA	Machine learning and AI research; data science and analytics; tech innovation (Silicon Valley, etc). Investing in tech businesses.
	Canada	Urban innovation (Sidewalk Labs is designing a district in Toronto's Eastern Waterfront to tackle the challenges of urban growth).
	China	Geospatial Industry 'parks' within tech city.
	Singapore, Western Australia	Geospatial business incubators.
Standards	Netherlands	Geonovum Coordinated management of a national set of geospatial standards.
	Norway, Sweden	Joining intelligent transport and geospatial standards.
	Germany	AAA model and roll out of 3D in a federal system.
	European Commission	INSPIRE standards are key to interoperability across Europe.

Pathway	Nations which could be considered for comparison	Learning point from practice modelled overseas
Partnerships	US	Blanket and quilt approach to national map; partnership model of US census.
	Netherlands	Kadaster and its partnership with private sector.
Capacity and education	USA	Geospatial skills certification programme.
	Australia and Netherlands	International Internships/fellowships into geospatial agencies paid by ODA budgets.
Communication and engagement	USA	USA: #1 in the GeoBuiz report for User Adoption Level.
	Singapore	Singapore: Govt/Gov Tech working with key Singapore agencies as both data providers and data consumers.

Appendix one: Case studies

Reference to Q.4

Case study: Project Iceberg: subsurface data collaboration

Project Iceberg is a collaborative project between OS, British Geological Survey and Future Cities Catapult to explore how to better capture, collect and share data about underground assets and geological conditions.

Currently there's a lack of information about the features beneath our towns and cities; there's incomplete data; and the approach to managing subsurface space is isolated and uncoordinated.

The aim of Project Iceberg is to demonstrate the value of interoperable data about the subsurface, including buried assets; to find a way of sharing all this information among a wide range of relevant organisations including utility and energy companies, the transport sector, street works planners and building developers, as well as the public sector.

Project Iceberg has found that there is a need to combine above-ground (e.g. existing city data systems) and below-ground information into one national single data model/data exchange framework which would allow the industry to share business developments and innovation activities. This is not a single map of the subsurface but a consistent framework into which data is supplied, assured, stored, accessed and analysed by a multitude of users in the short term, whilst appropriately safeguarding privacy and security.

These themes have now been picked up by the National Infrastructure Commission, in their report *Data for the Public Good*. It is hoped that by combining surface and sub-surface city data, the potential of new technologies can be realised. For instance, we would see augmented reality being used before any dig to safely identify the location of existing pipes.

For more information see: *os.uk/projecticeberg*

Case study: A prototype for combined data at the North East Underground Infrastructure Hub

Water, gas, electricity and telecommunications utility companies and local authorities have worked with OS on a 'sprint' as part of the 2018 Northumbrian Water Innovation Festival to develop a working prototype of what would be the region's first digital map of buried utility assets. *The Big Challenge, Going deeper underground - Can we build an underground map of the UK?* explored:

- the possibility of sharing infrastructure data held by the agencies involved
- the practical considerations of integrating underground data
- the overall business benefits around integrated data

The basic challenge was to gather insight into what pipes and cables there are in a section of ground before a hole is dug or a visit undertaken to a site.

A prototype model was built by OS' Consultancy and Technical Services team, with a view to exploring future pilot opportunities.

For more information see: *https://innovationfestival.org/ossprint*

Reference to Q.6

Case study: OS secondment to Group on Earth Observation (GEO)

GEO is a partnership of governments and organizations (*www.earthobservations.org/geo_community.php*) whose vision is for "a future wherein decisions and actions for the benefit of humankind are informed by coordinated, comprehensive and sustained Earth observations." GEO membership includes 105 Member governments (of which the UK is one) and 127 Participating Organizations comprised of international bodies with a mandate in, and/or use of Earth observations.

GEO is operating in alignment with three of the United Nations agreed agendas, the 2030 Agenda for Sustainable Development, the Paris Agreement, and the Sendai Framework for Disaster Risk Reduction. Each of these have different requirements for Earth observations, from monitoring to implementation and understanding. Having strong, coherent engagement with national governments, and the stakeholder community enables Governments to mobilise and commit to adequate levels of resources. This is underpinned through strong advocacy for broad, open data policies and practices. Together, the GEO community is creating a Global Earth Observation System of Systems (GEOSS) that will link Earth observation resources world-wide across multiple Societal Benefit Areas - Biodiversity and Ecosystem Sustainability; Disaster Resilience; Energy and Mineral Resources Management; Food Security; Infrastructure & Transportation Management; Public Health Surveillance; Sustainable Urban Development; and Water Resources Management - and make those resources available for informed decision-making.

OS sits on the UK GEO-CEOS Office Policy Delivery Group and helps to coordinates EO related activities through this group (chaired by Defra and UKSA) and has committed to fund a resource into the GEO Disaster Risk Reduction programme. This will form part of the UK contribution to GEO, but is in addition to the core budget contributions to the running of GEO (see blog post from the Defra Deputy Chief Scientific Advisor Iain Williams, and currently represents the UK on the GEO Executive Committee: *www.earthobservations.org/geo_blog_obs.php?id=273*).

The secondment seeks to supports the GEO Disaster Resilience work programme (*www.earthobservations.org/area.php?a=dr*) by increasing coordination of EO to forecast and prepare for disasters, to mitigate damage and to better manage and recover from disasters. EO contributes to disaster mapping and better mitigation and response, working within the Sendai Framework on Disaster Risk Reduction (*www.unisdr.org/we/coordinate/sendai-framework*). There is a need to align the Sendai Framework targets with the Paris Agreement and the SDGs, and thus there is a close alignment with the activity that OS is engaged with through the UN-GGIM.

Reference to Q.7

Case study: OS innovation in Bournemouth to support 5G telecommunications infrastructure

Geospatial data on the natural and built environments needs to be married with integrated meteorological, geological, ecological, social and economic data to enable planners to predict the optimal location of both full fibre broadband and potentially 5G infrastructure. By linking location with network, planners will be able to identify specific areas that are likely to require additional investment due to their remoteness or any land restrictions. Businesses and communities will be able to benefit from reliable coverage if telecommunications companies can anticipate and relocate networks to avoid natural or man-made obstructions, from tree foliage to buildings.

A recent project in Bournemouth sought to address this by employing an integrated digital twin approach. OS helped plan the implementation of 5G across Bournemouth by integrating over 30 local datasets, including Met Office weather data and OS augmented 3D maps accurate to within 1-2 centimetres, to create a richly detailed, interactive digital twin of the city. This work enabled planners to identify how local features, from lamp posts to hanging baskets, could interfere with 5G signal quality in every area, and allowed them to model the effect of wind and clouds on network coverage at different altitudes.

The project showed the potential for reducing the costs of 5G rollout by identifying the optimal locations for each antenna, and therefore delivering maximum benefit to the local community. The use of geospatial data in this way was able achieve a 40% reduction in the planned number of antennae in achieving total coverage across Bournemouth. Such efficiency would lay the foundation to make investment more attractive for private telecommunications companies, could save time and reduce risks.

If the Bournemouth project could be scaled up to a nationwide level, not only could planners predict the optimal location of antennae to avoid signal interference from nearby buildings, they could also identify the perfect location to increase digital productivity or boost business growth in a disadvantaged area. Unifying infrastructure data into a multi-layered ‘master map’ would allow companies to collaborate across sectors on new projects, from rail lines to 5G grids, ensuring that each new network aids the success of all the others, without an intolerable increase in risk. It would enable town planners to make whole system decisions rather than just optimising each network for individual performance.

For more information see: *www.ordnancesurvey.co.uk/5g*

Reference to Q.8

Case study: Smart Cities – the Manchester CityVerve project

OS was part of a public–private consortium awarded £10m competition by DCMS to run an Internet of Things Demonstrator project. The CityVerve project looked at how location data can be modelled, in order to give us

a better understanding of how a geospatial approach can enrich services and lives in smart communities of the future.

Smart City programmes all require accurate and interoperable mapping and location data to enable robust analysis. Without mapping, geography and Geographic Information Systems, it would be impossible to create a Smart City environment powered by the Internet of Things.

OS' role was to provide the geospatial framework upon which the project activity was based. Our location expertise and geospatial infrastructure supported use cases such as way-finding, road safety, and building asset management. In addition, we provided accurate location and attribution data for street-side assets, such as lighting, signs, and bus stops.

By sharing the lessons learned in developing people, processes and technology, OS is helping Smart City projects to use geospatial data and services to underpin a wide range of policy and business processes. Outcomes from this project may be applied to other areas of the UK and around the globe.

For more information see: *cityverve.org.uk/*

Case study: The benefits of a digital twin approach

A 'digital twin' is a realistic digital representation of all natural and built assets. An integrated, location-based map of UK infrastructure could be used to form an integral part of a digital twin of Great Britain: If this could be scaled up to a nationwide level, it would enable policy makers to more accurately plan monitor, predict and influence services like energy and smart transport.

Policy makers could identify the relationships between optimal economic or social outcomes and nearby infrastructure, and plan for effective upgrades. Everything from full-fibre networks to new rail lines could be built around boosting local healthcare or driving innovative new digital start-ups. Crucially, the impact of new infrastructure on local people and services and stress-testing of new networks could be modelled in the virtual world, before implementing them in the physical world.

More joined-up infrastructure planning through a digital twin approach would ensure systems worked together to deliver wider benefits. Research demonstrates that greater collaboration in planning and provision of services could save the UK economy £3 billion.

Achieving this vision will require a neutral convener of all sorts of infrastructure data, including location data. To facilitate this, all infrastructure data would need to be interoperable, easily shared and understood.

For more information see: www.ordnancesurvey.co.uk/blog/2017/10/digital-twin-new-*smart-city/*

Reference to Q.9

Case study: OS Net – a fundamental geospatial asset

The OS Net® network is the infrastructure which gives access to the national coordinate system of Great Britain.

The network consists of approximately 110 continuously operating, very precise Global Navigation Satellite System (GNSS) stations throughout Great Britain that stream the GNSS data in real time to a central server.

The server computes real time corrections to GNSS enabling OS surveyors to use GNSS at the centimetre level while updating the national map database. The data is forwarded to OS commercial partners who offer similar correction services. It's also archived and made freely available on the Internet.

OS Net makes the accurate determination of national standard coordinates much easier and more efficient for users who need accurate positioning, compared with traditional (pre-GNSS) methods. This technology supports an extensive range of mapping, engineering and environmental projects which would simply not be possible without it. Using a single receiver, a positional accuracy of 1-2 cm is achievable, depending on the equipment used and environmental factors.

For more information see: *www.ordnancesurvey.co.uk/business-and-government/products/os-net/index.html*

Case study: responding to customer requirements with the Open Zoomstack trial

OS Open Zoomstack is a comprehensive vector basemap showing coverage of Great Britain at a national level, right down to street level detail.

OS Open Zoomstack is designed to make OS map data more accessible and easier to use.

The advantages of Zoomstack include:

- The data is available in just one single data file and via an API. It is provided in easy-to-use formats to help customers to get started quickly
- The data is compatible with Geographic Information Systems (GIS), web, mobile and offline systems. It is highly customisable, giving customers the flexibility they need to complete their work
- Vector Tiles contain actual data (not just images) which can be interrogated and analysed. The high-definition mapping also renders quickly, giving a seamless experience

We use OS Open Zoomstack in our own mapping applications and we've had positive feedback from partners and customers who have participated in the trial.

For more information see: *www.ordnancesurvey.co.uk/zoomstack*

Case study: Geovation

OS is committed to innovation. Through the London Geovation hub, supported by both OS and HM Land Registry, we identify and invest in start-ups.

By encouraging small business growth, we are supporting Britain as a world leader in innovation, and expanding the use of geospatial data and technologies. Running a start-up incubator also gives us the opportunity to generate valuable insight on new technologies, markets and ways of working.

The world is moving faster, and we need to ensure we adapt to serve up our data rapidly for our customers. Geovation is a great example of where collaborating with new ideas and entrepreneurial energy creates space for fresh thinking. And it is the perfect place to explore how we can remain a forward-looking organisation.

For more information see: *geovation.uk*

Case study: OS data being used to predict coastal change in Scotland

The UK's Climate Change Risk Assessment (August 2017) anticipates that increases in sea level, coastal erosion and coastal flooding will affect Scotland's 'soft' coastlines and its coastal assets. Scotland's National Coastal Change Assessment (NCCA) aims to create a shared evidence base to support more sustainable coastal and terrestrial planning decisions.

The NCCA needed to establish what is erodible and what had already eroded. This was achieved by extracting the geo-rectified coastline position from OS 2nd Edition Country Series maps (1892-1905) and comparing it to both the 1970s and the current coastal position (updated by OS data, including coastal topographic data and tide lines and LiDAR datasets where available), to then estimate past erosion/accretion rates. Using the historic coastal change rates, the coastline position could then be projected into the future. Using the erosion rates combined with a number of socio-economic datasets, key assets at risk from future coastal erosion could then be identified.

Since the 1970s, 77% of Scottish 'soft' coast could move – but it hasn't. Meanwhile 11% of 'soft' coast has advanced more than 10 metres seaward, and 12% of soft coast has retreated more than 10 metres landward. If coastal change continued at these rates, the Assessment anticipated a 16% retreat and 9% advance over the next 37 years; more coast is experiencing erosion and that where it happens, it's twice as fast as before, putting many coastal assets at risk.

The NCCA's findings are informing existing strategic planning (Shoreline Management Plans, Flood Risk Management Planning, Strategic and Local Plans, National and Regional Marine Planning), as well as identifying areas which may remain susceptible in the coming decades, and therefore require supplementary support or protection.

For more information, including interactive maps, see: *www.dynamiccoast.com*

Reference to Q.17

Case study: OS data supporting the property and land sector

Across the land and property lifecycle there is critical need for location data, particularly in the siting and planning stages. A rising population, changing demographics, changes in buyer and social behaviours all impact on the demand and availability of land and housing. A lack of modernisation with across the land and property sector mean that productivity over the past 25 years, has grown by just 11%, in comparison to 41% nationally (ONS).

The number of 'Proptech' industries in the UK are growing, providing the sector with often niche solutions which address the specific market requirements of key players – estate agents, developers and surveyors. These companies are increasingly drawing on OS and other public sector data.

OS recently interviewed its partner community (including companies such as Landmark, Groundsure and Centremaps) to better understand the value they extract, their key tasks and their use cases for Geospatial data.

OS provides a range of low value, high volume property reports to support the lifecycle of land and planning which can be critical in due diligence processes, where inaccurate data risks corporate liability. OS geospatial data is used by our partners to support: site identification, site feasibility assessment, planning applications, 3D building modelling, and infrastructure planning.

We know that our partners value greater accuracy and the completeness of OS data. Value is attached to enhanced building attribution data, including: floor area, age, roof type, number of floors, construction type, and land attribution (classification, vegetation).

We know that our partners require improved accessibility, particularly through reliable APIs and FTP processes. OS is improving access to more useable data, for example by providing a portal for contextual mapping for Area of Interest or data attribution.

Our partners are also calling for improved standardisation and interoperability across government data sources. Greater value may be extracted from geospatial data if it can answer specific questions about, for example, flood risk or land availability.

There is an opportunity to open up the market to new users, as well as readying the market for the adoption of new technologies, which would improve land identification and feasibility assessment.

Reference to Q.18

Case study: OS data supporting financial services markets

The UK has largest insurance market in Europe and third largest in the world, generating 24% of Europe's premium income (Association of British Insurers, 2013). Furthermore, global IT Enterprise spending in the banking and securities market is set to grow 3% in 2018 (Gartner).

External influences and fraud are driving up risk levels in the insurance market. In addition, in June 2018, the Bank of England published a statement of policy for the Minimum Requirements for own funds and Eligible Liabilities (MREL), which is likely to lead to banks being required to reduce levels of risk. Accurate location data is used by both the insurance and banking markets to mitigate risk.

OS recently interviewed its partner community to better understand the value they extract, their key tasks and their use cases for Geospatial data. This research identified that partners in the financial services markets require enhanced capture of building attribution, including: volume, number floors, height, usage/classification, age, roof type, structure types, building foot print, internal building mapping, land attribution (use and cover, e.g. garden size); as well as more complete data about underground assets.

In common with our partners in the land and property sector, our financial services partners are also calling for improved standardisation and interoperability across government data sources. The solutions in this market are often complex, bespoke and able to integrate with existing business solutions/systems, alongside a range of data sources. Data analytics is prevalent in the financial services market particularly due to the analysis of data in the various risk models. Automating the completion of tasks such as calculating a rebuild cost, calculating flood risk, accurate flood modelling, calculating insurance premiums, or making decisions for mortgage lending, could lead to more cost-effective decision making in this key UK sector.

There may be an opportunity to better support financial services' risk analyses through making relevant public and private geospatial data available in a format which is interoperable, accessible and useable.

Geospatial Commission: Call For Evidence Response Questionnaire

Please submit your completed questionnaire to:

geospatialcommission@cabinetoffice.gov.uk.

Clearly title your email *'Call for evidence response'*.

About you and your organisation

Name	[Text redacted]
Organisation	Ordnance Survey Northern Ireland - Land and Property Services
Job title	[Text redacted]
Address	[Text redacted]
E-mail	[Text redacted]
Telephone	[Text redacted]

Please select which of the following best describes you as a respondent:

Respondent	**Please mark with a X**
Academic	
Business representative / trade body	
Central government	**x**
Charity or social enterprise	
Individual	
Legal representative	
Local government	
Large business (over 250 staff)	
Medium business (50 to 250)	
Small business (10 to 49)	
Micro business (up to 9)	

Other - please state	

Call for evidence - three key themes

We have identified three high-level themes that could help our approach to setting a strategy which are as follows:

1. **Supporting innovation in the geospatial sector**, exploring how to secure cutting edge skills, the right access to data, and opportunities from emerging technologies for the geospatial sector itself
2. **Enhancing the UK's geospatial assets,** looking at how best to align interests, avoid duplication, and instill best practice across the whole public sector
3. **Driving investment and productivity in geospatial applications**, asking in which wider sectors the most value lies from better exploitation and use of geospatial data, in the UK and internationally

Our questions

Q1. Is our view of the geospatial data types accurate? If not, what should be included or excluded from this?

"Geospatial data" and "positional data" are generally synonymous—it is unclear why the terms are differentiated and may lead to confusion with regards to terminology, particularly if both terms are used in strategy/policy papers. Positional Data maybe renamed Relatational Data if location is a secondary purpose.

Positional data includes x, y and z (height) information only—should 4D (time-series data) be included going forward? Useful for long-term monitoring e.g. coastal erosion and predicting future needs and trends

There may be another 'type' here relating to the linkages and business process triggers that are made possible through the sharing, use and management of the lifecycle change of the identifiers

The identifiers are a way of anchoring a wide range of attributes to or about a place - not just linking position to geospatial. This doesn't explain the benefits properly

Q2. In addition to current government policy, what are the areas of geospatial skills where the commission could best focus, to help ensure the necessary capability within the UK for the future?

Introduce GIS, mapping and spatial analysis early in education i.e. in primary school and continue through to university with specific inclusion in 3rd Level courses not traditionally aligned with geography (e.g., biology, computer science, politics and government, behavioural psychology, etc.).

Promote the incorporation of computer science and programming principles within 3rd Level geography curricula.

Explicit inclusion of geo-literacy in education boards' official curricula/objectives (e.g. make geospatial awareness mandatory from primary to 3rd Level).

Increase student support and access to GI-related courses and learning opportunities (e.g. cheaper GI courses, burseries, sponsorships, apprenticeships/placements, accreditation, etc.).

Include geo-literacy in curriculum/course objecives for those studying to become teachers (i.e., educate teachers). Schools both primary and secondary, where GI is included as a part of the curriculum. OSNI Academic licence (free for academic instruction) could aid this.

Q3. What are the geospatial skills needs and gaps in your organisations, how can these be most effectively addressed, and how can careers in the sector be best promoted?

Gaps in understanding computer science principles, specifically relational databases, web development and coding…these are not traditionally included as part of curricula for geography-related degrees—the majority of our staff have geography or geography-related degrees (see Q2 above regarding how this can be addressed in education). Furthermore, ICT gaps can be addressed by training; however access to training (as well as specialized software) is prohibitive. Promoting the development and/or access to low-cost and/or open source ICT-based training would be a solution.

Organization-induced separation of GI and ICT roles prohibit GI-based staff from developing computer science-related skills to augment GI skills (e.g. web app development)—the promotion and acceptance of computer science as part of GI staff's skillset would help alleviate this.

Basic understanding of cartographic principles (and related skills) seem to be declining as organizations (public, commercial, and even academic) rely more and more on digital visualization "templates" (e.g. web-based map viewers) to create aesthetically pleasing spatial analytical outputs. These skills can not be neglected in GI-related courses.

See question 2 to promote careers

Skills to enable efficient and accurate capture of imagery, DTM, DSM, NIR, LIDAR, Point Clouds
Skills to be able to capture and update databases using a range of methods, Field Survey, Mono and Stereo plotting, Drone survey and processing
Skills to enable the processing, storage and delivery of these large datasets
Skills to be able to manipulate, enhance, combine, query, this data with a wide range of other data to deliver new insights, improve and inform business processes.
Skills in setting up linkages to create multi-channel communications across a wide customer base to realise the value of geospatial identifiers

Use and enhance the NI Model of Mapping and Charting Grades and enhance the skills base (particularly database administration and IT skills) distributed across central and local government and build a sharing community of knowledge and expertise. Create a career path for this community similar to NISRA statisticians.

Q4. Are there any publicly or privately-held geospatial datasets that are currently challenging to access or use or of insufficient quality, but which you or your organisation would find valuable if these issues could be resolved? Please explain why this would be of value, and how access/quality could be improved?

Addressing data is challenging because there is no mandate to specify the use of a single authoritative addressing dataset for a given region/area. Consequently, there are cases where an address has multiple “forms” (e.g. a road might be spelled different ways, or referred to differently). This makes it difficult to address-match related datasets and requires arduous, often manual, processes to achieve. By mandating or even promoting the use of authoritative addressing databases, we can fully leverage interrelated datasets to streamline workflows and services (particularly in the public sector).

Utilities—including sub-surface—datasets (e.g. gas, electricity, etc.) are useful for local and emergency planning; however access to these datasets are minimal. Promoting increased access to—at the very least—basic utilities data would enhance public services and service delivery processes.

Datasets need to be maintained at a level of quality that make them useful (i.e. they need to be QA/QC’ed and managed properly); otherwise, their utility would be limited and could lead to poor (or wrong) decision-making. Data creators need to be incentivized to increase access to data without sacrificing data quality.

A single definitive address is by far one of the practical and useful pieces of work that could be delivered by the Geospatial Commision

Q5: Do you anticipate that any changes will be needed to the both address data and the wider address ecosystem, to support emerging technologies? Please provide evidence of value to support any proposed changes.

Standardized and authoritative addressing datasets are necessary to support any emerging technologies. Without standardization, information linked to the same location but referred to with different addresses/designations can not be fully utilized.

Intellectual property (IP) embedded in current addressing systems (e.g. Postcodes) limit access to addressing datasets (e.g. royalties/fees make using authoritative datasets cost-prohibitive). Attributes that are integral to addresses (e.g. Postcodes) should be open.

Q6: How should the commission be looking to develop the UK’s capability in Earth observation data, both technologically and to support an effective market?

Promote and enhance access to EO data. Develop an adequately sign-posted, accessible, centralized repository of authoritative EO data. Currently, it is difficult to identify appropriate and accessible EO data.

The UK must promote and develop its own EO platforms—particularly in light of Brexit.

The UK must promote and incentivize UK-based EO data/platform developers to enhance EO capabilities and make outputs more open to the public sector.

Seek to provide access to higher resolution imagery

Most of this data comes in standard formats and can be managed in existing software. One of the main problems with this data is storage and fast access to that storage. A significant opportunity would be to provide a cloud based infrastructure to store and provide fast access to 'the single source' for the full range of core geospatial datasets.

Q7. Which new technologies should the commission focus on to provide new opportunities to process and exploit geospatial data for economic growth?

IOT and Drone technologies should be promoted—but equally important, STANDARDS for data outputs to ensure they can be leveraged by users regardless of which IOT/Drone platforms they were initially derived from.

BIM/3D modelling technologies and data outputs need to be developed within a standardized framework—again, to ensure data interoperability.

Q8. How can geospatial data and applications be used to support enhanced roll-out of future technologies?

Standardization of data is necessary to support any roll-out of future technologies. Due to the fast and dynamic changes in data capture technology, standardization and data interoperability is a fundamental method for future-proofing geospatial data.

Q9: What are the options for how public sector organisations could continue to invest in maintaining and enhancing our geospatial data assets?

The UK's Geospatial data is ranked second in the world in respect of quality, currency and completeness. This standard of authoritative state sponsored data can only be sustained by continued maintenance, development and enhancement funded by a 'user pays' cost recovery business model

Revenue generated through licensing to government departments and large businesses should be used to invest in the maintenance and development of high quality, authoritative datasets. This should also be used to offset costs associated with making datasets more accessible to small and medium enterprises.

Promotion and development of standardization methods coupled by mandates/ enforcement of these standards.

Public sector staff need to be supported to develop skills and resources to ensure sufficient knowledge of best practice methods/standards.

Promotion and development of cross-departmental technologies (e.g. centralized data stores and spatial data infrastructures that facilitate cross-departmental workflows) and staff skills to harness those technologies.

Q10: What areas of the underpinning geospatial infrastructure such as positioning technologies, including GPS and indoor positioning systems, and geodetic networks and frameworks to support them, should we be prioritising the development of, in order to support the emerging requirements for geospatial data?

Common Standards for all of the above including BIM, 3D, and linkages between the two – to be developed and prioritised.

Q11: What role should the private sector have in both the development and maintenance of the underpinning infrastructure and enhancing the UK's geospatial data assets?

Private sector e.g. utilities must develop and maintain datasets to the same (if not higher) standards as public bodies to ensure data interoperability.

Greater sharing of information collected by the private sector could enhance existing datasets and reduce duplication of effort.

Encourage the release of private sector data to the public domain. Additionally, private sector data created/generated as part of public-funded works must be released to the public (or at the very least released to the government body funding the works) BY DEFAULT. Promote—if not mandate—access to public private partnership-based datasets.

Utilise the geospatial identifiers supplied and maintained by NMAs

Q12. Do you face challenges when working with geospatial data from across the public sector? If so, what are they and how could value be better released? Are there any technical remedies or standards that could be adopted to improve the interoperability of geospatial data? Please provide supporting evidence of what these remedies could help to accomplish.

The implementation and use of GUIDS is crucial to improve the interoperability of geospatial data across the UK

Standardization and linking public sector datasets must be encouraged (if not mandated). The use of standards and identifiers to ensure data links and interoperability will increase the value of public sector data.

Supporting public sector efforts to increase data quality processes and methods is integral to optimizing data viability—be it financial support, increasing access to training/knowledge transfer, best practice, standardization, etc.

Develop, promote and support central government data stores/platforms via coordinated sign-posting/marketing/communications strategy, as well as political support and financial resources.

Increase access to utilities and utilities-related datasets to enhance local development planning.

Support local government (Local Councils) in their efforts to leverage GI and spatial datasets.

Mandate a framework for data sharing agreements between public sector bodies in times of emergency events when access to sensitive datasets is required.

Q13. How can the Geospatial Commission act as a more effective customer for geospatial data on behalf of the public sector?

Ensure the scope and remit of GC is appropriate and that GC has sufficient capital to fund initiatives and also remit to enforce standards and promote best practices.

GC should also make data-based legislation more accessible/understandable to public sector staff/bodies who are tasked with meeting these obligations (e.g. support local/regional government with EU INSPIRE Directive compliance).

Assist with 3rd party Intellectual Property (Royal Mail) in addressing datasets allowing better use to be made of the addressing datasets with fewer restrictions.

Q14. Are there any additional geospatial datasets, from the other partner bodies or other sources, that the public sector would derive significant benefit from having access to, that might have novel and valuable use cases? What would that access look like?

Ensure that the focus for spatial data INCLUDES MARINE/AQUATIC data as well as land/terrestrial data. At the moment, there is an over emphasis on land-based spatial datasets and neglect for water-based datasets (e.g. benthic datasets, water column [3D marine] data, etc.).

In Northern Ireland, cross-border datasets are integral to public services; so enhancing cross-border collaboration and supporting facilities, technologies, and data workflows with the Rep of Ireland should be a priority.

Q15: How can we best develop a single UK strategy, ensuring alignment between the individual strategies across the UK while still allwoing for regional variations?

GC should seek to develop a core UK Strategy and in a federated approach the devolved administrations should seek to align their regional strategies to it.

It is difficult to envisage that there could be an effective and properly focussed single UK strategy

Q16: How can we best ensure effective local authority coordination and sharing of best practise, using location data to better deliver public services?

Include Local Government in the UK and regional strategies

High level strategies must include local councils who should be encouraged (if not mandated) to prioritize geospatial data, workflows and processes within local council work plans.

Support for local council staff via info-sessions as well as access to geospatial training and resources.

Q17: As a result of this analysis, we are prioritising the exploration of possible initiatives in the high-value categories identified:

- **property and land**
- **infrastructure and construction**
- **mobility**
- **natural resources**
- **sales and marketing**

What are the existing or potential geospatial applications which could be scaled-up or developed in order to capture economic value? (We would particularly welcome responses from industry and other bodies engaged in these sectors.)

Drone and 3D datasets should be scaled-up and made more accessible (e.g. cheaper data products).

Use of Geoanalytics tools/applications to leverage crowdsourced and/or commercial datasets (e.g. Facebook data, VISA credit card locational data, etc.)

Q18: Are there any other areas that we should look at as a priority?

Promoting geoliteracy in traditionally non-GI based government departments (particularly at the senior management level) to enable them to leverage their datasets within a spatial context and increase/release value and efficiency. For instance, some NI Executive Departments have minimal understanding of how geo-enabling their datasets can increase their utility and effectiveness in decision-making and service-delivery processes.

Q19: What are the main potential private and public sector innovations that will rely on the use of geospatial data to rollout, and are there corresponding regulatory challenges?

Mobile-based data technologies (including UAVs) are rife with regulatory challenges (e.g. privacy).

The use of AI and AR for public services also have geospatial components with regulatory issues that need to be worked out (again, privacy).

Smart Cities project has been facilitated through the free access to OSNI mapping using the no cost OSNI Innovator Licence for development purposes.

Q20: How best can we make the UK's presence in the international geospatial world more visible?

Active participation in international spatial standards groups (e.g. Smart Cities Standards) is necessary to ensure UK's geospatial industries develop in line with (or ahead of) the rest of the world.

Active development of UK's earth observation platforms(s) and support for related/dependent small businesses and government bodies.

Q21: Where should the UK be looking for points of comparison overseas? Who are the other international exemplars? What best practice is being modelled overseas that we can learn from?

Eurogeographics standardise and join 43 Countries geospatial data to international. They are an easy single point of contact to compare and contrast the work of the national mapping organisations within these countries.

Thank you for your time in completing your response to our call for evidence.

Any questions, please get in touch with the Geospatial Commission via geospatialcommission@cabinetoffice.gov.uk

Geospatial Commission: Call For Evidence Response Questionnaire

Please submit your completed questionnaire to:

geospatialcommission@cabinetoffice.gov.uk.

Clearly title your email *'Call for evidence response'*.

About you and your organisation

Name	[Text redacted]
Organisation	(1) Police PURG Rep / Gwent Police (2) Avon & Somerset Police ***On behalf of all Police Services in England & Wales***
Job title	[Text redacted]
Address	[Text redacted]
E-mail	[Text redacted]
Telephone	[Text redacted]

Please select which of the following best describes you as a respondent:

Respondent	**Please mark with a X**
Academic	
Business representative / trade body	
Central government	
Charity or social enterprise	
Individual	
Legal representative	
Local government	
Large business (over 250 staff)	
Medium business (50 to 250)	

Small business (10 to 49)	
Micro business (up to 9)	
Other - please state	**X** **Police (Emergency Service)** *On behalf of all Police Services in England & Wales - responses collated and fed through this questionnaire.*

Call for evidence - three key themes

We have identified three high-level themes that could help our approach to setting a strategy which are as follows:

1. **Supporting innovation in the geospatial sector**, exploring how to secure cutting edge skills, the right access to data, and opportunities from emerging technologies for the geospatial sector itself
2. **Enhancing the UK's geospatial assets,** looking at how best to align interests, avoid duplication, and instill best practice across the whole public sector
3. **Driving investment and productivity in geospatial applications**, asking in which wider sectors the most value lies from better exploitation and use of geospatial data, in the UK and internationally

Our questions

Q1. Is our view of the geospatial data types accurate? If not, what should be included or excluded from this?

As a police service, we agree with the overall definition however we believe it requires some clarifications in order to ensure the geospatial data types **include** (i.e. do not omit) the following specific data sources:

- ***Live*** **positional data (i.e. GPS) in point (2):** relating to objects in movement such as vehicle tracking (e.g. ship, plane, HGV, cars [which may derive from a black box]), smart phones or airwave devices, electronic tagging, etc.
- **"Passive data" in point (2):**
    - This is relating to the use of spatially referenced objects / services from which we can derive location of "users" at a specific date and time. For example: use of phone masts whilst using telecommunications; vehicles being registered through Automated

Number Plate Recognition (ANPR); credit card usage at ATM or shop; Oyster card use at tube stations, individual on CCTV footage.

- This is going to be an area of geospatial data growth in terms of generation but also for consumption, especially within the police service when it is required to identify the location of individuals as part of an investigation.
- This may need to be regulated – if so by whom? Geospatial commission?
- Currently it is provided by service providers (e.g. telecoms company etc.) in a variety of formats and coordinates (e.g. eastings and northings; lat / long decimal values; lat / long in degrees, minutes, seconds. The variety of coordinate's formats makes it daunting for novices and less accessible than it should be. There is scope to set UK standards for these companies too.

In addition to the above specific data sources, we believe it is important that the following two are also mentioned and clearly stated in the definition:

- **Geospatial Web Services in point (4):** it is not clear that the services providing geospatial data as an **input,** such as Data as a Service (DaaS), are included – *it seems to refer to analytics therefore "output" products.* We believe that the way Geospatial data is being delivered and the way in which it is consumed, is an important and growing aspect of geospatial data types.
- **Geospatial Data formats:** This could be added as there is a strong requirement for interoperability of data and compliance with OGC standards; with also a need to influence suppliers in adopting / allowing the consumptions of those formats.

Q2. In addition to current government policy, what are the areas of geospatial skills where the commission could best focus, to help ensure the necessary capability within the UK for the future?

As a Police Service, staff in charge of the "Geospatial portfolio" in the various police forces are from a variety of backgrounds and therefore, systems are set-up in very disparate ways – with sometimes no GI expert at all. For example, staff may have a background in IT (developers, DBAs, etc.) or policing (ex- Police officer). In addition to this, with budget reductions, vacant GI posts are often not replaced and the number of GI professionals in policing is decreasing. This makes it challenging for police forces to embrace geospatial capabilities in a uniform way – geospatial data may not be kept up-to-date and the potential of geospatial data and applications are not realised. It also hinders innovation.

We believe that there are a number of ways the Geospatial Commission can help GIS capabilities in the future:

(N.B: some of the points below do not only refer directly to police service.)

(1) Skills / Pathways:

- Improve the range of GI qualifications (i.e. not just university degree) for young people but also to scale up to current GI professionals
- Availability of a range of accredited skills / pathways to prove capability and recognise acquired experience and skills (e.g. RGS chartership)
- Increase incentives for GIS apprentiships / internships: current recruitment requires a lot of experience, often too focused on traditional GIS skills like digitisation etc. There needs to be routes to acquire a more rounded business skills – where understanding the business and its applications of GIS will drive continuous improvement.
- Improve the provision of low cost workshops / training for GI professionals and users in a way that is not driven by suppliers but rather by the needs of the users.

(2) Promote GIS and geospatial data nationally

- Raise the profile of GIS nationally for all sectors = e.g. utilise **GIS Day** as an opportunity
- Actively promote GI as an enabling service that is holistic and accessible to all, not just limited to specialists / expert practitioners
- Widen the scope of (and normalise) geospatial, to demonstrate there is more benefits to gain than just the traditional “niche” analyst type role
- Promote geospatial and the use of GIS in schools within different strands of the curriculum: i.e. not just as mapping in geography, but as a IT skill or as a problem solving tool in science, history, etc.

(3) Increase buy-in and demand for GI Skilled jobs:

- Educate Top Executives of large employers (including in the public sector) on the benefits of investing in GI teams for data creation (e.g. LLPG custodians) and data consumption (GIS teams) to ensure recognition that the roles are needed within organsations.
- Tackle the “mystery / too hard to understand / too technical” stigma of GI tools / roles at senior management level

Q3. What are the geospatial skills needs and gaps in your organisations, how can these be most effectively addressed, and how can careers in the sector be best promoted?

As mentioned in Q2 above, GI professionals in the police service come from very different backgrounds therefore geospatial skills / gaps can be very different.

Nowadays, challenges faced require a blend of different skills from a range of roles (GIS technicians, geographers, cartographers, database administrators, programmers, developers, analysts…) alongside a sound understanding of the business and how to use GI within it. Also with the growth of software providers (private or open source) and formats, there is also a requirement for GIS professionals to be conversant in many applications / formats / programming languages.

Often, in the police service, the GI portfolio is given to only one individual servicing one or more organisation(s) (e.g. alliances) with sometimes different systems and applications. Finding these rounded and holistic skills in a single individual is extremely rare and therefore unlikely.

It is also a huge **resilience** issue and in turn, skills are never achieved if under-resourced.

(1) **Gaps:** Below are some examples of the current gaps / needs found in our organisations:

- Geospatial basics (e.g. Gazetteer / GIS skills) for those who come from a non geo-spatial background, e.g. IT backgrounds
- Training for geospatial content editing - understanding topological and geometry checks (e.g. digitising polygons with no slivers / overlaps)
- Database administration and programming skills for GI professionals that are coming from a geography background
- Understanding of Open Source packages, formats, and standards
- Basics of Open Data and the standards surrounding this (not known in the police service due to traditional culture of dealing with sensitive / personal information).

(2) In **order to address this**, ideally you would require:

- A team or a pool of individuals (as opposed to one!) from various backgrounds and with various sills working as a team in GIS to be able to harvest all skills necessary
- Recruiting based on attitude to learning and lateral thinking is also key to invest in individuals who are able to adapt to rapid changing technologies and big data
- Appreciation of GI capabilities at a senior level **securing investment** in team / staff – *this does not have to be in each police forces but could be shared services such as more regional*

/centralised team or centres of expertise supporting various GIS functions / or police service accross the country

- There is also often a lack of **ownership** of the GI portfolio within individual police forces. Often because it is not understood, or because police officers turnover is high due to promotions. The lack of staffing means that there is limited visibility as well and the agenda is rarely pushed forward.
- Working with education and higher education to teach the right skills for a GI career. At the moment universities still teach traditional GIS skills such as:
    - how to use Desktop GIS,
    - problem solving applied to human or physical geography,
    - GIS technologies rather than new GIS methods as used in the real world.

(3) Promotion of GI careers:

- Recognition of GI roles at all levels of the organisation
- Standardise where GIS sits within an organisation so that there is a clear career path and organisational structure to enable development\promotion opportunities. Is GIS located in the right department to maximize GIS investments and operational efficiency?
- Make a GIS career an attracting option by offering salaries that are actually commensurate with the skills and experience required
- Better sharing of outstanding / innovative GIS work with benefits gained from these.

We believe that this quote summarises the importance of investing in GI staff within the geospatial industry:

"No GIS can be a success without the right people involved. A real-world GIS is actually a complex system of interrelated parts, and at the centre of this system is a smart person or team who understands the whole."

Dr. Roger Tomlinson. Thinking About GIS: Geographic Information System Planning for Managers, 5th edition. ISBN: 9781589483484.

Q4. Are there any publicly or privately-held geospatial datasets that are currently challenging to access or use or of insufficient quality, but which you or your organisation would find valuable if these issues could be resolved? Please explain why this would be of value, and how access/quality could be improved?

(1) Accessibility vs usability vs interoperability

A large range of geospatial datasets are available to the police service (from Ordnance Survey, Lidar from Environment Agency, as a few examples) however, although easily accessible, they often cannot be utilised due to a range of issues:

- Datasets are in a format that cannot be readily consumed in the GIS software used
- Datasets are not provided as a web services which could be readily consumed within GIS software. *N.B: there is also a need however to have "offline backups" – this is particularly the case for Command and Control systems accessing web services. Ideally "live feeds" should be our goal – but security, stability and worries about viruses / systems falling over, prevent trailblazing these technologies for use at the sharp end of policing.*
- Datasets require large amounts of pre-processing in order to be used, lack of resources mean this data becomes unusable, for example:
    - To create a 3D building layer, OS MasterMap has to be downloaded in gml per tile, this data then needs to processed and transformed (using ETL) into another format, building height has to be downloaded separately in order to cross reference the information and allow for the extrusion.
    - This also applies to ONS demographics data which is shared at a geographic level (e.g. Output Areas [OA] or wards) – the OA / ward layer needs to be downloaded separately to the OA / ward excel sheet. The excel data is merged to the OA point / ward boundary and only then can we calculate the aggregation of population for our own geography.
- Datasets are in a standard that the suppliers are slow to adopt – therefore we have to wait on our suppliers to make the necessary change to be able to use it (e.g. this was and is still the case for Address Base).Additionally, police forces are often lacking the budget to upgrade / replace systems required.
- Datasets are not fit for purpose for police / emergency service use: e.g. AddressBase relates mostly to addressable locations however a large proportion of crimes / incidents etc. occur outside an address e.g. street junction, at the bus stops or taxi ranks, etc. (see Q5 and Q17)
- Require additional information at additional cost (e.g. OS Highways – speed data; AddressBase – Business Names)
- Datasets are not readily usable with the Contingency Planning & Emergency / Disaster Response systems of choice **Resilience Direct**

(centrally funded) which is available for all partner agencies to share and view data in a one common system. Ideally all geospatial layers required for police use and emergency responses should be readily available within Resilience Direct.

(2) Improvements required

- Due to the varied software limitations, consumers require the data in a range of formats; also to view / download or consume as web services / APIs to cater for everyones needs.
- Data standards and good practice, as well as robust metadata are required to identify data quality / currency / timeliness – to ensure there is trust in the data
- A single repository / access point for all information would be an ideal way forward, removing the need for individual data sharing agreements, mandating open standards and formats, metadata etc. (as a minimum, there would need to be templates & guidance for data sharing)
- Key geospatial identifiers (such as UPRNs) need to be promoted / mandated as standards of recording locations in all sectors to allow easy combination of diverse data sources, as well as sharing data
- Realising the value of data to monetise it, requires consumers / developers to rely on quality, consistency, and up-to-date data (accompanied by metadata and support) on which to base apps, services, tools and analysis.

(3) Specific Datasets:

- **Transport infrastructure** (such as bus routes & bus stops, train lines & stations, tube lines & stations, tramway lines and stops): within London, TfL is ahead of the game in creating and sharing the information, however sometimes the information can be hidden away. In the rest of the country this is very flaky. Often due to the subcontracting of the data (e.g. bus) and therefore not accessible or poorly digitised.
- **Electoral Roll:** the police service currently relies on private sector partners to supply this information (matched to UPRN and AddressBase). This is also captured by local authorities and some process could be put in place to ensure the information is linked to UPRNs at source, as well as being provided as an extra dataset centrally and as part of a government agreement. This could release significant cost savings.
- **Passive Data coordinates standards**: mobile telephone and ANPR data is available but is supplied in many different formats, even using different

versions of Lat/Long, meaning complex GIS processes to import and use the data – making it less accessible than it should be. Mobile phone mast data can also be shrouded in secrecy and commercial confidentiality – these standards should be improved and openness encouraged via a central agreement (see Q1 – passive data).

- **Commercial geolocation for Emergency / Disaster response**: better integration with commercial geolocation data (e.g. Facebook Disaster response, Google Person Finder, etc.) would be useful in order to understand the personal impact of incidents; but also mass search of individuals in a disaster scenario.
- **National infrastructure & services**: e.g. gas, water, electricity, sewers, disused tunnels. This is lacking at the moment.
- **Demographic datasets:** it would be useful to have high-level demographics already geospatially referenced and downloadable via the ONS geoportal. For example, some key statistics like total population (with gender, age, and ethnicity breakdown), deprivation, or segmentation to avoid the processing duplication required to use the data.

N.B: this is only a fraction of the data required… we would love to have accurate, consistent and up-to-date locations such as CCTVs, Telecoms masts, etc.

The list would be too long for this question.

Q5: Do you anticipate that any changes will be needed to the both address data and the wider address ecosystem, to support emerging technologies? Please provide evidence of value to support any proposed changes.

(1) Address Base is an essential geospatial data source to police service

As a police service we have mostly migrated to use AddressBase for linking crime / incidents to a location. Correct addresses are a key element of crime / incident / intelligence data quality and enables the:

- Accurate referral of cases to partner agencies and services (e.g. victim support, crown prosecution service, probation, etc.)
- Display and visualisation of crime / incidents / intelligence in turn enabling a better response, understanding of short / long-term patterns and ability to provide prevention measures
- Review and granular reporting of performance, allowing for a culture of continuous improvement

- Sharing of information (police.uk)

However, we face many issues relating to AddressBase products which mean not all the above can be achieved effectively. We believe we are still a long way off achieving a fully standardised address database.

(2) Improvements required

- **Disparity between local custodians**: Police forces often pan across many local authorities and therefore experience first-hand the discrepancies in the standards of recording – specifically:
    - Variations in the use of classifications codes, but also mandating the granularity of the classifications codes. We rely heavily on this to extract locations such as care homes, schools, etc.
    - Varying choice of nomenclature, different interpretation of the Data Entry Convention Standards (DEC).
- Addresses are only a fraction of where crimes / incidents occur there is a requirement to have consistently **recorded non addressable locations** such as (*non exhaustive list):* See point (3) below.
    - CCTV cameras operated by local authorities (some include, some don't)
    - Road junctions: OS highways can derive road junctions. Point road junctions are necessary for the police to record road collisions so by including within AddressBase Premium, the data could be consumed through our gazetteer systems the same way other locations are consumed.
- **Street Naming & Numbering** (SNN) legislation is not fit for purpose, resulting in different behaviours between creating authorities which in turn produces different quality address data. Default recommendation should be to integrate the SNN function into the Gazetteer management team to provide a single point of contact and expertise, again resulting in better quality and more consistent addresses. This would give local services a lever to challenge outdated entrenched internal behaviour.
- The **cross referenced Royal Mail Address** (PAF) in AddressBase includes incorrect information and there is no requirement for them to makes changes when the error is fed back to them. This adds data quality issues and confusion amongst users, especially those who don't understand the addressing systems and who will tend to choose Royal Mail as the correct data (even though it is not).
- The level of **complexity** of the AddressBase Premium product (relational database) can be daunting for some. This also relies on police forces to

procure systems to handle the data in the format required – budget limitations mean this is not always possible.

- **Promote AddressBase as the single source for address data.** OS make the claim that 'Points of Interest' is the most comprehensive, location-based directory of all publically and privately-owned businesses, education and leisure services in Britain. Surely, this should be AddressBase.
- Enforce **UPRN** as a mandatory requirement for address information sharing.
- Invest in **address subtypes** for ease of information retrieval. For example, Children's Home – Local Authority, Children's Home – Private, Social Housing.
- **Capturing change of Commercial / Business Names**:
    - The **lag and/or absence of current business name data** as well as the consistency of how this data is held is an issue reported by each force a simple means to capture / report new business names to custodians so they can rapidly update changes would be a key benefit for all address users.
    - The **long delivery cycle of AddressBase updates** (COUs) on a 6-week basis is often in reality translated to a 12-week delay from the date of the actual LLPG update of the address. In this period, many business names change and those changes are then not available to Command & Control call handlers. The current COU process may be acceptable for commercial purchasers however not for emergency services. These delays mean police forces create work arounds which in turn cause issues and additional work there is a key requirement to set up a system where emergency services receive a daily AddressBase update.
    - It has been noticed that in large towns and cities, open products like Open Street Map are often more up-to-date than AddressBase and also products like OS Point of Interest.
    - It is often wrongly assumed that business rates departments record addresses and details of businesses and pass this information on to the LLPG custodians in their organisations.
    - There is a strong requirement for a **universal "record" of business names t**o be created and maintained, free at point of use. This should mandate the accurate use of the UPRN and only record the business name at the location of the business itself (a different classification could be used for residential premises used for a

business?). It would also encourage a single view of an address for a business - at the moment a business can legitimately have a different version of its address than the official one recorded on the LLPG/NAG.

(3) Additional Data required in AddressBase for the Emergency Service

As explained above, there is a requirement to collate additional locations beyond just addresses within AddressBase, and to be at no additional cost.

- **Type 3 Streets and Junctions** – see initiative which has begun with Ordnance Survey / Geoplace at the request of police forces.
- **Features referring to another**: There are 'pond' addresses that refer to being 'x metres' away from another feature or a premise such as a farm, when the farm itself (or the feature) is not included as an address in its own right.
- There is a need for central guidance for best practice to help local authorities argue the case internally to adequately resource both spatial data and gazetteer maintenance.
- **Big national infrastructure companies** (e.g. utilities) should be contributing their geospatial features in AddressBase to integrate this data centrally, e.g. telecom masts, sub-stations. This would avoid the duplication currently experienced (e.g. electricity substations are sometimes added by local custodians, then duplicated from OS).
- There is a requirement for local authorities to see how widely and essential their data has become to services across Britain, and that it is no longer just for a tax collecting purposes. The focus and the use of the data is now fitting a wider purpose and this should be reflected in the collection of non-addressable locations.
- **Creation of a Emergency Services Gazetteer & features.** If there is a desire to keep the main AddressBase product focused on properties, establish parallel supplies with the additional information for consumption by anyone who needs to share these key locations – for example, an emergency service gazetteer. This could build on the existing data supply, including data from identified definitive sources to increase consistency and minimise the additional burden on local authorities.

Q6: How should the commission be looking to develop the UK's capability in Earth observation data, both technologically and to support an effective market?

This is a new area for police forces, however there may be some scope in utilising earth observation data more effectively in the police service. Below are some ideas:

- Using good quality and high resolution satellite imagery which may be more up-to-date than the aerial imagery which requires a plan to fly it
- Use of live feeds of satellite data to support major incidents / disaster responses
- Using remote sensing as an additional tool with aerial or drone imagery, due to:
    - Autonomous operation (reduced constraints on line of sight)
    - Weather and night capable
    - Multiple sensors
    - Cost minimised – e.g. if thermal imagery was enabled – it could save sending helicopter out which is very costly
    - Safety (no risk over populated area) – e.g. policing festivals, large events

Q7. Which new technologies should the commission focus on to provide new opportunities to process and exploit geospatial data for economic growth?

As a Police Service, we believe that the Geospatial Commission can:

(1) In the first instance, provide focus on technologies that **simplify the downstream ease of consumption** of reliable data, as such:

- Web Services and centralised data centres
- AI and machine learning to acquire, clean, process and derive enhanced new datasets from big data (e.g. understanding people's movements, etc.)

(2) **Enable the demonstration of capabilities / art of possible**:

- Drones / 3D modelling and visualisation
- Virtual / Augmented reality (e.g. for training, and response in poor visibility conditions; to flag risks, etc.)
- Voice Activated Services (e.g. Alexa, Siri) – Where is my nearest…? Please call my nearest ….

(3) Lead/ encourage growth of alternative competitive solutions

- Open Source integrated GIS platform (including web)

Q8. How can geospatial data and applications be used to support enhanced roll-out of future technologies?

As mentioned in previously , use of geospatial data and applications in future technologies depends heavily on:

- The quality and timeliness of geospatial data is key for enabling use and trust from developers of future technology.
- Standards compliance and security is needed to ensure the above.
- Access and availability is also key.

However, without a sound infrastructure to consume these datasets / applications – future technologies won't be able to use them. There needs to be a comprehensive network dedicated to **high speed connectivity** across the country and not limited to high populated areas. By connectivity, we mean:

- Adequate Phone coverage (4G and now 5G rollout)
- High speed broadband / bandwidth: whilst this is a government priority, it is very slow to be delivered
- Increased open WiFi hotspots

Q9: What are the options for how public sector organisations could continue to invest in maintaining and enhancing our geospatial data assets?

As mentioned in Q3, GIS professional numbers are decreasing in the police sector but also in other public sectors. Whilst geospatial data use is booming, the numbers of staff creating the datasets is decreasing and stretched.

These stretched resources cannot provide the best geospatial datasets, or outputs. They don't have the time to educate / advocate GIS within their organisation. The function then becomes less visible and misunderstood.

We would hope the Geospatial Commission can influence the below:

- Secured / ring-fenced funding in organisations for minimum staff enabling the resource of both:
  - core basic GIS functions (e.g. LLPG, GIS officers)
  - And a senior GIS champion to promote the capabilities within the organisation.
- Mandate the requirement for each public sector to provide GIS capability (thus secure GIS jobs).
- Mandate that the strands from the new National Geospatial Strategy strands are included in individual organisations' digital and IT strategies.
- When investment / procurement is made in software providers (not just GIS software but all software using geospatial data), mandate the compliance with GI and OGC standards (e.g. addresses must comply with BS6777 standards) – i.e. a must to receive the contract / investment.

- Access to central resource pool / encourage collaboration to encourage resilience. Ensure this is not at the expense of being isolated from the business – remove duplication.
- Create a sense of pride and competition within organisations by incentivising the growth in geospatial maturity of the organisation – for example, organising awards to encourage demonstrations of innovation in GIS – need for both carrot and stick approaches.
- Establish / subsidise a large UK geospatial conference which encourages sharing of good practice, where people can learn from their peers, etc. without being tied to a specific private supplier. – e.g. GeoPlace, esriUK conferences. AGI, FOSS4G, UK Mapping Festival etc. are all paying events, so therefore do not show a great turn out. Public sectors have no budget for sending staff to payable conferences.
- Encourage more case studies to be shared in order to show what can be achieved.

We believe organisations should both be given incentives, and sanctions when required.

Q10: What areas of the underpinning geospatial infrastructure such as positioning technologies, including GPS and indoor positioning systems, and geodetic networks and frameworks to support them, should we be prioritising the development of, in order to support the emerging requirements for geospatial data?

In the police service, we are subject to data being provided in many coordinates systems, and in many formats. Converting batch lat/long coordinates to easting & northing is the most frequently asked questions by our users. Unfortunately, the various forms of recording lat/long (decimals, vs degrees, min, sec) can also confuse general users.

Through this exercise, it has noticed that there is a **lack of knowledge** about the free standalone coordinate converter tool provided by OS (**GridInquestII)** amongst police GI professionals themselves:

- More promotion of the tool should be done.
- An update of the GUI and an easy step by step guide would be useful too.

Q11: What role should the private sector have in both the development and maintenance of the underpinning infrastructure and enhancing the UK's geospatial data assets?

We believe the private sector should play a large role, specifically:

(1) Innovation & skills

- Enabling Research and Development into future technology using the data available (e.g. large GIS companies)
- Leading / Advisory role (e.g. large GIS and consultancy companies)
- Training

(2) Infrastructure

- Improve connectivity: e.g. improve 4G\5G coverage, especially for emergency services, as well as broadband speeds, and WiFi hotspots.
- Utility companies to share information / notify LLPG with new assets e.g. ATMs, telecoms masts, etc.

(3) Software developers / suppliers

- Suppliers to adapt to change in data standards quickly (e.g. AddressBase) in order to add value to the software (as opposed to charging for the change), thus avoiding pitfalls of being stuck with legacy systems that can't adapt to new and emerging technology.
- Be engaged with developing common data standards and services, and get rewarded (endorsement) for contributions and commitments to those standards.
- Enabling easier data sharing through ensuring connectivity, safety and security, and allowing wide use of web services.

Q12. Do you face challenges when working with geospatial data from across the public sector? If so, what are they and how could value be better released? Are there any technical remedies or standards that could be adopted to improve the interoperability of geospatial data? Please provide supporting evidence of what these remedies could help to accomplish.

While some data is of known quality, maintained and delivered from a single location, this is not the norm. There is too much diversity in how datasets are captured, maintained and published or shared across the public sector.

There is a greater need for standards applied to key datasets with a minimum publication standard.

Areas where value and leadership can be added include:

- There needs to be a wider range of delivery method, formats (interoperability) and readily consumable web services (e.g. WFS, WMS, REST services, APIs).

- Common standards in using unique identifiers to record assets (e.g. utilities, schools, even our own estate departments!).
- Common standards in using unique identifiers (UPRNs) to enable more frequent sharing of information between partner agencies (e.g. markers, flags, risks, alarms) – which can be easily and automatically cross-referenced and therefore minimise the risk of errors.
- There are some challenges in gaining data at point level (address) from health organisations.
- Procurement contract have to include the need to meet geospatial data standards.

For example: for a given dataset, have a minimum defined product, published in defined formats which would allow moderation of compliance and compilation to a single dataset for easy consumption. For users of the data, and to encourage contributors, a compiled summary view can highlight who contributes, if there are any gaps and when the data was updated.

Q13. How can the Geospatial Commission act as a more effective customer for geospatial data on behalf of the public sector?

We believe the Geospatial Commission can help the public sector by:

(1) Establishing a new flexible mapping agreement

As a police service, we have felt the change in the geospatial industry and experienced how the public sector is very slow in reacting to it. The current PSMA is also demonstrating how inflexible the contract is and how we are served with a set of products. It is currently most unsatisfactory as it leads to end user groups investing considerable time, effort and frustration over very protracted timeframes, having to 'beg', 'badger' and 'cajole' to chase obvious enhancements. Whilst these will undoubtedly deliver real world saving and benefits many are still undelivered (ref. to the street junction work - emergency service gazetteer).

The new public mapping contract / agreement needs:

- To have a flexible framework and governance to manage evolving needs rather than a product based fixed contract.
- To include the means to force / leverage delivery of changing needs (pick & mix)

(2) Effectively gathering and using public sector stakeholders views:

- Carry on the great consultation work (like PSMA event).
- Maintain involvement of PURG / GISG.

- Include GI professional secondments from various sectors to Geospatial Commission to contribute and work on projects.
- Allow for a threat / risk matrix view of requirements by public sector consumers (i.e. low voice for single agencies as opposed to lots of weight from local authorities as large numbers).

(3) Enabling a central centre / repository of expertise and data

- It would be beneficial if the GC could exert authority to obtain additional datasets whether from public or private sector (i.e. public sector could build a business case which is taken on by the commission) – *possibly free of charge for emergency services.*
- Collate / publish materials on good practice / good business cases so senior ranks and managers can appreciate what is possible and help to understand need.
- Allow for a bank of skilled professionals to offer support to public sector / organisations with skill gaps.

Q14. Are there any additional geospatial datasets, from the other partner bodies or other sources, that the public sector would derive significant benefit from having access to, that might have novel and valuable use cases? What would that access look like?

Some ideas of additional datasets that would be useful to the police service (see Q4) - *(other than the improvements and additional features within AddressBase):*

- **Transport infrastructure** (such as bus routes & bus stops, train lines & stations, tube lines & stations, tramway lines and stops): within London, TfL is ahead of the game in creating and sharing the information, however sometimes the information can be hidden away. In the rest of the country this is very flaky. Often due to the subcontracting of the data (e.g. bus) and therefore not accessible.
- **Electoral Roll:** the police service currently relies on the private sector partners to supply the information (matched to UPRN and AddressBase). This is also captured by local authorities and some process could be put in place to ensure the information is linked to UPRNs at source, as well as being provided as an extra dataset centrally and as part of a government agreement. This could release significant cost savings.
- **Commercial geolocation** for Emergency / Disaster response: better integration with commercial geolocation data (e.g. Facebook Disaster response, Google Person Finder, etc.) would be useful in order to understand the personal impact of incidents; but also mass search of individuals in a disaster scenario.

- **National infrastructure & services**: e.g. gas, water, electricity, sewers, disused tunnels. This is lacking at the moment.
- **Demographic datasets:** it would be useful to have already high-level demographics already geospatially referenced and downloadable via the ONS geoportal. For example, some key statistics like total population (with gender, age, and ethnicity breakdown), deprivation, or segmentation to avoid the processing duplication required to use the data.
- **DTM, DEM, and Lidar**: We are aware it is currently provided by the APGB… however it would be good to have it as an easily accessible format e.g. a web service which enables the draping of data on top of it / extrusion of datasets in 3D when draped on top of it.
- **Building Information Modelling** (BIM) models to be available in a suitable / usable / interoperable form of large buildings (e.g. stadiums) and infrastructures to help integrating with GIS 3D visualisation for event planning / responses or contingency planning / disaster responses.
- **Aerial imagery** / **Satellite imagery**: is important to add operational context – not to be lost in the PSMA contract *(N.B: internal communication within the police sector is ongoing to promote take up).*
- **Planning – Basement development.**
- **Land Registry data** (land ownership) without having to pay or request separately to land registry.
- **DVLA data** linked to UPRN so we can link addresses of vehicle registered keepers.
- **Road Network (e.g. Highways):** Speed information should be included as standard in the OS highways Network.

Q15: How can we best develop a single UK strategy, ensuring alignment between the individual strategies across the UK while still allowing for regional variations?

As a police service, we welcome a UK National Geospatial Strategy which can lead a common vision with agreed key objectives / strategic strands. This can then be adopted and developed locally within regions, but also across various sectors.

For this, we believe the GC needs to:

- Review / scope already written national / regional strategies:
    - Highlight similarities which can be adopted in the single strategy

    - Identify and acknowledge current areas of local differences
- Work on a proposal with representatives:
    - Propose and consult on a common vision and key strategy strands
    - Create a national strategy that will drive / be included in local IT / digital strategies
    - Set some key minimum national standards within local organisations (i.e Basic Minimum Requirements), still allowing for innovation.
- Test / Review:
    - Establish a technical pilot for this framework to test how this would work
    - Identify a few key datasets to provide an effective pilot and undertake this work end to end
    - Review regional progress and validity of the national strategy through grassroots' results
- Keep the strategy alive through annual review, adapting to technology changes / progress and highlighted challenges.

Q16: How can we best ensure effective local authority coordination and sharing of best practise, using location data to better deliver public services?

We believe local authorities' work needs to be in support of the Geospatial Commission vision, objectives and mandate.

The existence and quality of the addressing datasets are testament to what can be achieved, the governance model and resourcing in place to drive this is an essential component of marshalling so many disparate bodies to produce usable end products.

There is a case that to deliver on spatial data will require similar governance, drive and co-ordination.

(1) Key principles and success factors to be applied to the creation, maintenance, co-ordination, monitoring and needs matching of spatial data are:

- Standards
- Best practice
- Submission and publication framework
- Monitoring and reporting
- Statutory / contractual obligation

(2) How to ensure there are local resources to undertake the work?

- Help with funding of GI / LLPG roles (stretched resources currently with some councils struggling to survive)
- Use the best channels to communicate with practitioners - national conference, governance structure, demonstrable benefit, etc.
- Awards and communication about innovation in public services
- Sanctions when appropriate when investment in capabilities and delivery of geospatial data is not adequate.

Q17: As a result of this analysis, we are prioritising the exploration of possible initiatives in the high-value categories identified:

- **property and land**
- **infrastructure and construction**
- **mobility**
- **natural resources**
- **sales and marketing**

What are the existing or potential geospatial applications which could be scaled-up or developed in order to capture economic value? (We would particularly welcome responses from industry and other bodies engaged in these sectors.)

As a police service, we recognise that the economic value in these categories is clear however there is an additional category with a huge intrinsic value which is missing: **protection of life.**

(1) Multi-agency Incident Transfer

- Extensive work has been undertaken to pilot and prove the benefit case of electronically exchanging incident information between emergency services and local partners. In addition to major incidents, it is a framework for exchanging information between partners needing joint response or shared intelligence on locations.
- A detailed study and proof of concept pilot was sponsored by Cabinet Office, Welsh Government and ACPO members from both the emergency services and the commercial sector to look at the problem of exchanging incidents between agency control rooms.
- The link below gives fuller details of the work to date - https://www.geoplace.co.uk/-/the-uprn-underpinning-the-multi-agency-incident-transfer-mait-standard

(2) The creation of an Emergency Service Gazetteer

- Wide scale adoption of AddressBase across the public sector is a tremendous endorsement in the quality and coverage and is testament to the work invested in developing it.
- Adoption by emergency services has identified additional datasets of importance to delivering the public protection role, it has re-enforced the need for additional information to be captured and made available without compromising the existing user needs. Currently missing but required are:
    - key datasets of benefit to emergency services to consistent and high quality standards which classifications already exist in AddressBase e.g. public toilets, CCTV cameras, bus stops
    - Daily updates delivery mechanism / system
- Identify key datasets and primary sources, many of which can be managed centrally (provide full coverage and no additional demand on local authorities – e.g. road junctions, motorway marker posts ; public phone boxes ; electricity substations)
- Use the existing addressing DTF to load into command and control / key systems
- Create a subset of “sensitive” locations to be used securely by emergency services partners only which emergency services can access on top of other public sectors.

(3) Other potential valuable dataset: Full National Transport Network

- To build on the success of TfL: an integrated National transport network (road, bus, rail, etc). This would create a lot of interest nationally both for public consumption but also for identify gaps in service provision for various private companies. Specifically related to police service, it would also help with police enquiries re- missing persons, potential warrant / search for fugitive; as well as ensuring our elderly population are able to access police premises, etc.
- This would require to mandate:
    - public transport licensees to provide data to build national datasets suitable to underpin public travel apps such as Citymapper but nationally

- the creation of spatial data by private sub contractors (e.g. bus companies, any contracted bodies) and given back to Local authorities / emergency services

Q18: Are there any other areas that we should look at as a priority?

As a police service, we believe that the priority is :

- Increase the number of **web-based data provision / delivery** – as covered previously – i.e. data needs to be provided as an easy and readily consumable format (e.g. web services or APIs). For the public sector, this would minimise efforts and processing duplication across various organisations. E.g. a PSMA zoom stack – which can be cached / used offline on mobile device also. For the public sector, web-services of PSMA products should be free of charge.
- Better address \ location error \ omission reporting processes.
- Improve data sharing capabilities between public and private sector organisations.
- Influence **suppliers to adopt British geospatial standards** as well as OGC standards.
- **SNN legislation & processes** to be reviewed and updated: currently are too old, not fit for purpose and underpin the whole address creation process – e.g. only mandatory to give a number to a building if it is residential as opposed to business. Making it mandatory for all, would help with the issue of business names changing – as we could use a standard address.
- **Public Transport network** (i.e. TFL but nationwide) – as outlined in Q17 for economic return.

Q19: What are the main potential private and public sector innovations that will rely on the use of geospatial data to rollout, and are there corresponding regulatory challenges?

Within the police sector, we believe the main innovation that do rely currently on the use of accurate geospatial data is:

- The Adoption of Geofencing – dynamic alerts based on location: police forces are increasingly looking at using such technologies to alert officers on risks / current priorities and for tasking purposes.

- Augmented Reality – again looking at embedding risk markers for locations as augmented reality - this could be used to inform officers / staff of risks at a particular location they are deployed to, or other emergency services staff when attending incidents. This has been demonstrated to many police forces by Aligned Assets (gazetteer software provider) with their XDM module.
- Moving public sector to (secure) cloud to enable better collaboration – e.g. Resilience Direct – but currently Resilience Direct does not really consume live feed and require continuous static upload.

In general, and more long-term, we recognise that public transport operated by autonomous vehicles (e.g. autonomous buses) will require very accurate highways and street furniture geospatial data. However we do not believe this affects the police service at present.

Q20: How best can we make the UK's presence in the international geospatial world more visible?

We need the Geospatial Commission to become the forefront of the UK geospatial industry and increase the UK visibility internationally by:

(1) Bold statements / headlines

- Strong leadership making bold news and big decisions:
  - Establishing key geospatial data standards
  - Undertake key projects of public benefit (Emergency service gazetteer / infrastructure to support MAIT)
  - Commit to / provide funding for (public) spatial sector
  - Foreign standards (adapt and build)
  - Key attributes to monitor
  - E.g. FULL data release of base mapping – bold but brave!!!

(2) 'Geospatial Commission' as "International Centre of Geospatial Expertise"

- Create a sub-body of the 'Geospatial Commission' as an "International Centre of Geospatial Expertise/ Excellence" – creates interest as it gives the sense the body is already expert.
- Recruit best international geospatial experts.
- Capturing good practice and Return On Investment examples - promoting them at international conferences to international audiences.
- Become the defacto location to host international geospatial conferences.

- Geospatial commission comms campaign to showcase UK geospatial at high profile organisations (e.g. United Nations, World Bank – e.g. re-use of geospatial for human geography, economy).
- Increase UK involvement/ investment in geospatial emergency response charities e.g. MapAction / Team Rubicon.
- Understanding what other countries have or do not have, and find a niche that nobody has exploited yet (benchmarking ourselves).

Q21: Where should the UK be looking for points of comparison overseas? Who are the other international exemplars? What best practice is being modelled overseas that we can learn from?

We believe that a good place to start is:

- **USA:** the United States of America have always led geospatial policies / software & open data ideologies. There may be some lessons to learn from their Federal Geographic Data committee standardisation work…which aims at standardising geospatial data across states: https://www.fgdc.gov/standards with regards to the national strategy allowing for regional differences.
- **Canada :** Canada produces world class geospatial software (e.g. Safesoftware FME; Latitude geographics Geocortex, Geotime, etc.…)
- **China and India** are an emerging / growing market with a lot of services being outsourced to India, and new GIS software / training services developed (e.g. GIS247 in China).

Thank you for your time in completing your response to our call for evidence.

Any questions, please get in touch with the Geospatial Commission via geospatialcommission@cabinetoffice.gov.uk

Geospatial Commission: Call For Evidence Response Questionnaire

Please submit your completed questionnaire to:

geospatialcommission@cabinetoffice.gov.uk.

Clearly title your email *'Call for evidence response'*.

About you and your organisation

Name	[Text redacted]
Organisation	Postal Address File Advisory Board
Job title	[Text redacted]
Address	[Text redacted]
E-mail	[Text redacted]
Telephone	[Text redacted]

Please select which of the following best describes you as a respondent:

Respondent	**Please mark with a X**
Academic	
Business representative / trade body	**X**
Central government	
Charity or social enterprise	
Individual	
Legal representative	
Local government	
Large business (over 250 staff)	
Medium business (50 to 250)	
Small business (10 to 49)	
Micro business (up to 9)	

Other - please state	

Call for evidence - three key themes

We have identified three high-level themes that could help our approach to setting a strategy which are as follows:

1. **Supporting innovation in the geospatial sector**, exploring how to secure cutting edge skills, the right access to data, and opportunities from emerging technologies for the geospatial sector itself
2. **Enhancing the UK's geospatial assets,** looking at how best to align interests, avoid duplication, and instill best practice across the whole public sector
3. **Driving investment and productivity in geospatial applications**, asking in which wider sectors the most value lies from better exploitation and use of geospatial data, in the UK and internationally

Our questions

Q1. Is our view of the geospatial data types accurate? If not, what should be included or excluded from this?

Do not neglect the importance of addressing.

Q2. In addition to current government policy, what are the areas of geospatial skills where the commission could best focus, to help ensure the necessary capability within the UK for the future?

No response.

Q3. What are the geospatial skills needs and gaps in your organisations, how can these be most effectively addressed, and how can careers in the sector be best promoted?

None.

Q4. Are there any publicly or privately-held geospatial datasets that are currently challenging to access or use or of insufficient quality, but which you or your organisation would find valuable if these issues could be resolved? Please explain why this would be of value, and how access/quality could be improved?

The Postcode Address File Advisory Board (PAB) is not strictly a geospatial body. However, the Board is charged by Ofcom with looking after the interests of the users of the Postcode Address File (PAF) dataset which, whilst strictly a listing of addresses to which postal operators and deliver mail, is used widely for other purposes such as identity confirmation, by commercial companies such as insurance providers to calculate fees, or by government to delineate catchment areas for schools and hospitals etc.

The PAB would welcome ancillary datasets to the PAF, such as the file of properties Not Yet Built or that of Multiple Residence, or the postal re-directions file being made available for data analysis. As with all datasets, however, it is essential that appropriate investment continues to be made to ensure that data are timely, relevant and accurate.

Q5: Do you anticipate that any changes will be needed to the both address data and the wider address ecosystem, to support emerging technologies? Please provide evidence of value to support any proposed changes.

What is an address? The answer will vary according to user requirements. Postal operators want to know where they can deliver mail – and this was the origin of the Postal Address File. Emergency services need a wider definition which will include, for example, parks and recreation spaces. Others may have different requirements. Whatever they are, however, the prime requirement is that a dataset should be relevant, current, comprehensive and accurate. Our experience of comments on the PAF is that, within reason, pricing is not as much of an issue as ensuring PAF accuracy. This perhaps argues for a comprehensive address file which could be interrogated according to the various user requirements.

Q6: How should the commission be looking to develop the UK's capability in Earth observation data, both technologically and to support an effective market?

No response

Q7. Which new technologies should the commission focus on to provide new opportunities to process and exploit geospatial data for economic growth?

No response

Q8. How can geospatial data and applications be used to support enhanced roll-out of future technologies?

Geospatial data might be restricted to addresses that do not move. However, recent developments in order fulfilment suggest that a wider remit, to include the location of assets that are mobile, but at any one time can be related to geospatial data, could be important.

Q9: What are the options for how public sector organisations could continue to invest in maintaining and enhancing our geospatial data assets?

Organisations in the public sector currently benefit from a central Public Sector Licence (PSL) for PAF which enables them to use the file without direct payment. The PAB would support the extension of centrally purchased licenses for groups of users that would replicate the arrangements for the public sector licence. In principle this could include the government purchasing an all-embracing licence for any UK registered body, though given the importance of data quality (see Q5) it would be necessary to create safeguards so that political exigencies did not adversely affect the funding of a high-quality dataset.

Q10: What areas of the underpinning geospatial infrastructure such as positioning technologies, including GPS and indoor positioning systems, and geodetic networks and frameworks to support them, should we be prioritising the development of, in order to support the emerging requirements for geospatial data?

The PAB would suggest that geospatial data should be regarded as 3 dimensional rather than the traditional two-dimensional views (i.e. should cover matters above and below ground level).

Q11: What role should the private sector have in both the development and maintenance of the underpinning infrastructure and enhancing the UK's geospatial data assets?

PAB experience with the Postal Address File has been that private sector solutions providers have been imaginative in linking postal delivery addresses to other datasets and incorporating the results into software solutions. This suggests that granting access to public sector geospatial data on relatively low-cost terms would be a good way forward. We do not advocate free access to the data as we fear that the absence of income would inevitably lead to a reduction in quality assurance by the data managers; and we would wish to see big entities that are multi-data enterprises pay an appropriate fee for geospatial data.

Q12. Do you face challenges when working with geospatial data from across the public sector? If so, what are they and how could value be better released? Are there any technical remedies or standards that could be adopted to improve the interoperability of geospatial data? Please provide supporting evidence of what these remedies could help to accomplish.

No response

Q13. How can the Geospatial Commission act as a more effective customer for geospatial data on behalf of the public sector?

No response

Q14. Are there any additional geospatial datasets, from the other partner bodies or other sources, that the public sector would derive significant benefit from having access to, that might have novel and valuable use cases? What would that access look like?

No response

Q15: How can we best develop a single UK strategy, ensuring alignment between the individual strategies across the UK while still allwoing for regional variations?

No response

Q16: How can we best ensure effective local authority coordination and sharing of best practise, using location data to better deliver public services?

No response

Q17: As a result of this analysis, we are prioritising the exploration of possible initiatives in the high-value categories identified:

- **property and land**
- **infrastructure and construction**
- **mobility**
- **natural resources**
- **sales and marketing**

What are the existing or potential geospatial applications which could be scaled-up or developed in order to capture economic value? (We would particularly welcome responses from industry and other bodies engaged in these sectors.)

There is an obvious link between the property and land category of geospatial data and enhancing the Postal Address Fikle.

Q18: Are there any other areas that we should look at as a priority?

No response

Q19: What are the main potential private and public sector innovations that will rely on the use of geospatial data to rollout, and are there corresponding regulatory challenges?

No response

Q20: How best can we make the UK's presence in the international geospatial world more visible?

No response

Q21: Where should the UK be looking for points of comparison overseas? Who are the other international exemplars? What best practice is being modelled overseas that we can learn from?

No response

Geospatial Commission: Call For Evidence Response Questionnaire

Please submit your completed questionnaire to:

geospatialcommission@cabinetoffice.gov.uk.

Clearly title your email *'Call for evidence response'*.

About you and your organisation

Name	[Text redacted]
Organisation	Publica (Forest of Dean, Cotswolds, Cheltenham and West Oxfordshire Councils)
Job title	[Text redacted]
Address	[Text redacted]
E-mail	[Text redacted]
Telephone	[Text redacted]

Please select which of the following best describes you as a respondent:

Respondent	**Please mark with a X**
Academic	
Business representative / trade body	
Central government	
Charity or social enterprise	
Individual	
Legal representative	
Local government	**x**
Large business (over 250 staff)

Small business (10 to 49)	
Micro business (up to 9)	

Other - please state	

Call for evidence - three key themes

We have identified three high-level themes that could help our approach to setting a strategy which are as follows:

1. **Supporting innovation in the geospatial sector**, exploring how to secure cutting edge skills, the right access to data, and opportunities from emerging technologies for the geospatial sector itself
2. **Enhancing the UK's geospatial assets,** looking at how best to align interests, avoid duplication, and instill best practice across the whole public sector
3. **Driving investment and productivity in geospatial applications**, asking in which wider sectors the most value lies from better exploitation and use of geospatial data, in the UK and internationally

Our questions

Q1. Is our view of the geospatial data types accurate? If not, what should be included or excluded from this?

It is an accurate description of Geospatial data and encompasses all data types, but could it include examples in each case to help expand on the description?

Should 'Geospatial services' be Included in a 'data' definition?

Q2. In addition to current government policy, what are the areas of geospatial skills where the commission could best focus, to help ensure the necessary capability within the UK for the future?

Street Naming & Numbering – Legal guidance, best practice
Address data – promotion of the dataset
Local Authority derived data

Q3. What are the geospatial skills needs and gaps in your organisations, how can these be most effectively addressed, and how can careers in the sector be best promoted?

- GIS Officer roles being reduced – we need better awareness of importance of role and Geospatial data within Local authority
- Role of LLPG Custodian so intergral but often under estimated and under resourced. A Statutory function responsibility should surely receive an increased pay scale
- More links with local schools colleges and Universities. Represenation at carreers events. Work experience opportunities for Geography and IT students

Q4. Are there any publicly or privately-held geospatial datasets that are currently challenging to access or use or of insufficient quality, but which you or your organisation would find valuable if these issues could be resolved? Please explain why this would be of value, and how access/quality could be improved?

- Terrier/ Land and Property Information is held in a variety of formats and often incomplete. Historic deeds not electronically captured and ownership boundaries not digitised.
- Land Registry data for Private ownership – Would be a useful layer but obviously restricted as there is a cost per search
- Utilities – Gas pipe lines, Overhead cables, water, drainage – Would like to see better coverage in a downloadble/useable format
- Business Rates data - not easy to match with Local Land and Property Data due to poor locational information (lack of commercial unit layout plans)

Q5: Do you anticipate that any changes will be needed to the both address data and the wider address ecosystem, to support emerging technologies? Please provide evidence of value to support any proposed changes.

- Real world accuracy of address data and street data needs to improve with the introduction of technologied like autonomous driverless vehicles. ie. not just satisfying the Geoplace quality checks
- Better SNN guidance and consistent processes to simplify and speed up processes and get change data outthere more quickly
- Street furniture asset recording to provide a database of physical locations in Urban environments to better support WiFi networks/internet of Things/Smarter cities
- We could strive to make the recording of Land parcels more precise. eg What3Words. How can the UPRN be used in conjunction with these technologies?

Q6: How should the commission be looking to develop the UK's capability in Earth observation data, both technologically and to support an effective market?

Q7. Which new technologies should the commission focus on to provide new opportunities to process and exploit geospatial data for economic growth?

Q8. How can geospatial data and applications be used to support enhanced roll-out of future technologies?

- Improved accuracy of address data locations and UPRN currency
- Better coverage to a higher degree of precision (as above)

Q9: What are the options for how public sector organisations could continue to invest in maintaining and enhancing our geospatial data assets?

- More guidance nationally for SN&N
- Consistent National guidelines for Local government Geospatial data collection with regards to acceptable formats, schema and metadata.
- National central repository/database for Local Government data sets eg. TPO, Conservation, Green spaces, Local Plan Policies, SHLAA, Terrier data eg. As we have done with national Brownfield register

Q10: What areas of the underpinning geospatial infrastructure such as positioning technologies, including GPS and indoor positioning systems, and geodetic networks and frameworks to support them, should we be prioritising

the development of, in order to support the emerging requirements for geospatial data?

Increase precision and accuracy of GPS which needs to be supported by improved 4/5G networks and wifi networks in Urban areas to further enable geospatial data on mobile devices

Q11: What role should the private sector have in both the development and maintenance of the underpinning infrastructure and enhancing the UK's geospatial data assets?

- Share end user experiences and best practice Case studies.
- Improvement of Mobile Data networks/WiFi networks
- Construction Industry – more communication on completions and commercial unit layouts
- Improved Promotion of latest Geospatial system technologies to public sector

Q12. Do you face challenges when working with geospatial data from across the public sector? If so, what are they and how could value be better released? Are there any technical remedies or standards that could be adopted to improve the interoperability of geospatial data? Please provide supporting evidence of what these remedies could help to accomplish.

- Continued Promotion of the UPRN, NLPG to enforce adoption across Public sector
- Consistent National guidelines for Local government Geospatial data collection with regards to acceptable formats, schema and metadata.
- National central repository/database for Local Government data sets eg. TPO, Conservation, Green spaces, Local Plan Policies, SHLAA, Terrier data eg Brownfield register

Q13. How can the Geospatial Commission act as a more effective customer for geospatial data on behalf of the public sector?

- Set specifications for quality, accuracy, currency of data – how it should be delivered etc.
- Quality standard goal setting/milestones
- Could we introduce financial penalties or incentives for local government geospatial data provider to help achieve targets/standards
- Promote the importance of the role of LLPG/GIS/Spatial professionals within local government

Q14. Are there any additional geospatial datasets, from the other partner bodies or other sources, that the public sector would derive significant benefit from having access to, that might have novel and valuable use cases? What would that access look like?

- Mastermap WMS feed
- Other spatial reference systems eg What3words
- Emergency Services data
- Utilities data

Q15: How can we best develop a single UK strategy, ensuring alignment between the individual strategies across the UK while still allwoing for regional variations?

Challenge Local authorities to work together on local and regional Geospatial strategies that should follow the same format as a UK strategy and carry consistent themes.

Encourage regions to identify local variations in their geospatial data and highlight what their regional themes and data challenges are.

Q16: How can we best ensure effective local authority coordination and sharing of best practise, using location data to better deliver public services?

Direct and effective communication with Local governments – not just GIS/LLPG contacts but CEOs and senior management teams – especially those who are responsible for collection of Key geospatial data sets.

Regular, regional engagement meetings involving GIS professionals AND other Key stakeholders from Local authorities.

Use financial incentives/penalities to encourage better practices around geospatial data collection

Q17: As a result of this analysis, we are prioritising the exploration of possible initiatives in the high-value categories identified:

- **property and land**
- **infrastructure and construction**
- **mobility**
- **natural resources**
- **sales and marketing**

What are the existing or potential geospatial applications which could be scaled-up or developed in order to capture economic value? (We would particularly welcome responses from industry and other bodies engaged in these sectors.)

Q18: Are there any other areas that we should look at as a priority?

Q19: What are the main potential private and public sector innovations that will rely on the use of geospatial data to rollout, and are there corresponding regulatory challenges?

Q20: How best can we make the UK's presence in the international geospatial world more visible?

Q21: Where should the UK be looking for points of comparison overseas? Who are the other international exemplars? What best practice is being modelled overseas that we can learn from?

Thank you for your time in completing your response to our call for evidence.

Any questions, please get in touch with the Geospatial Commission via geospatialcommission@cabinetoffice.gov.uk

Geospatial Commission: Call For Evidence Response Questionnaire

Please submit your completed questionnaire to:

geospatialcommission@cabinetoffice.gov.uk.

Clearly title your email *'Call for evidence response'*.

About you and your organisation

Name	[Text redacted]
Organisation	Registers of Scotland
Job title	[Text redacted]
Address	[Text redacted]
E-mail	[Text redacted]
Telephone	[Text redacted]

Please select which of the following best describes you as a respondent:

Respondent	**Please mark with a X**
Academic	
Business representative / trade body	
Central government	**X**
Charity or social enterprise	
Individual	
Legal representative	
Local government	
Large business (over 250 staff)	
Medium business (50 to 250)	
Small business (10 to 49)	
Micro business (up to 9)	
Other - please state	

Call for evidence - three key themes

We have identified three high-level themes that could help our approach to setting a strategy which are as follows:

1. **Supporting innovation in the geospatial sector**, exploring how to secure cutting edge skills, the right access to data, and opportunities from emerging technologies for the geospatial sector itself
2. **Enhancing the UK's geospatial assets,** looking at how best to align interests, avoid duplication, and instill best practice across the whole public sector
3. **Driving investment and productivity in geospatial applications**, asking in which wider sectors the most value lies from better exploitation and use of geospatial data, in the UK and internationally

Our questions

Q1. Is our view of the geospatial data types accurate? If not, what should be included or excluded from this?

It's broadly accurate. Inclusion of a temporal dimension might be beneficial: spatio-temporal change is of relevance to a broad audience.

Q2. In addition to current government policy, what are the areas of geospatial skills where the commission could best focus, to help ensure the necessary capability within the UK for the future?

Geospatial data handling and stewardship skills need considerable investment to fully harness the potential benefits of the data assets we possess and are creating.

Capability and capacity in relation to both technical and business-oriented skills needs to be expanded.

Q3. What are the geospatial skills needs and gaps in your organisations, how can these be most effectively addressed, and how can careers in the sector be best promoted?

See above. Spatial data skills should not be developed in silos but integrated into wider business operations.

RoS is building spatial-data analytical capability, internally and within the wider Scottish analytical community, through participation in initiatives such as sponsorship of MSc students, the new Scottish Data Science Accelerator programme, and other opportunities arising through programmes such as the Scottish-Government-led Scottish Public Sector Analytical Collaboration (SPACe) – e.g., to enable greater interchange across collaborating public sector organisations. New graduate recruits to RoS are supported with good technical training and opportunities to engage with projects within the wider business being developed as part of RoS' on-going business transformation programme. RoS has a strong outwards-focus ethos and actively seeks collaboration with our stakeholders to develop partnership working, e.g., through participation in the Scottish Government-led geospatial stakeholder group. Opportunities for geospatial work at RoS are also promoted through national events such as The Datalab's annual Data Talent day

for students.

Q4. Are there any publicly or privately-held geospatial datasets that are currently challenging to access or use or of insufficient quality, but which you or your organisation would find valuable if these issues could be resolved? Please explain why this would be of value, and how access/quality could be improved?

Spatial data on ownership (and other rights): RoS is not a surveying organisation and collecting spatial data is not within our public task, hence the critical reliance by us on work by OS. We would welcome improvement to feature attribution and lifecycle information as we are required to ensure land register titles are maintained on the most current version of the base map. This specifically relates to distinguishing the difference between topographic mapping and ownership/occupation of land.

Quality is clearly important, but at an appropriate level of granularity for the work we need to do; too much information via MasterMap updates is as much a problem as too little. We are keen to achieve improved partnership and alignment of workflows across OS and ourselves to harness the available data to level best value.

Currently, the frequency of MasterMap updates doesn't align well with our business requirements, with variable frequencies for different components. A consistent approach to surveying across Scotland would be very helpful – particularly, for example, for new housing estates (whether in urban or rural areas), with consistently timely updates.

Critically though, RoS wishes to avoid any degradation of current standards and updates frequencies. Maintaining resourcing for MasterMap updating is essential to us given our dependence upon this for our Public Task.

Improved availability, quality and interoperability of data that is being made available by the public sector would be beneficial. Scotland's Land Information Service, ScotLIS, provides a unique opportunity to provide information based upon geospatial data in one place, meeting the needs of people involved in transacting land and property (and members of the public). Efforts to date looking at the inclusion of data from local authorities has proved challenging due to the reasons mentioned (namely quality).

Q5: Do you anticipate that any changes will be needed to the both address data and the wider address ecosystem, to support emerging technologies? Please provide evidence of value to support any proposed changes.

RoS notes issues in relation to:

- The address data life-cycle
- Consistency, given variable practices across local authorities.
- A single (rather than multiple) sources of addressing truth would bring value
- Clarity over licensing for re-use

Whilst different organisations have had different purposes for addressing (e.g., for deliveries, for local service provision), there would be considerable benefit for a single

address database.

Whilst Address Base Premium (ABP) describes itself as the canonical addressing system for the UK, it has issues and is not fit-for-purpose for all applications. ABP reflects the concept of address used by the content contributors (Royal Mail and Local Councils, with postal delivery or identifying geographical assets underlying the model). Hence, while ABP represents the superset of addresses used by the Royal Mail and Local Councils it does not represent the set of all addresses used in the UK. Addresses that fall outside the *operational use* of the Royal Mail and Local Councils do not appear in ABP.

For RoS, addressing for flatted properties presents considerable challenges, given different approaches which then need to be tied into a single approach for surfacing data to citizens and to businesses via platforms such as our Scotlis land and property data portal (see www.scotlis.ros.gov.uk).

Furthermore, the *lifecycle* of an address becomes critical, particularly for those businesses that deal with properties before they are allocated a formal address (land registers, builders, utilities and banks). Organisations such as RoS have better change intelligence at these areas.

Key to the future will be referencing geo-locations (with which addresses simply coincide), and it would be worth re-visiting ISO B7666. Each address in ABP is associated with a Unique Property Reference Number (UPRN). A UPRN can be used as a core reference geography to support address attribute interoperability within and between organisations. RoS would like to explore options such as minting by us of UPRNs as geo-location identifiers. It is not possible to predict the UPRN for a new address. Without the ability to create (mint) UPRNs those affected businesses have a data management issue.

Other issues are around

- Service Level Agreements in relation to update frequencies.
- Future proofing: how will UK addresses respond to challenges around, e.g., 3D, Room based addressing, Arbitrary addressing and drone delivery? (How much longer will the use of streets and buildings for addresses remain relevant?)

ABP is likely to be the dominant formal addressing system in the UK in the short-term but might become heavily disrupted. Issues with formal addresses (national in scope, not predictable and relative to underlying street/building infrastructure) have resulted in the development of a number of informal addressing systems that challenge traditional addressing. There are a number of challenges associated with such global frameworks - the key issues revolve around arbitrary area representations, elevation and licence constraints. However, there is the potential that algorithmic address systems will become the dominant addressing system during this century.

Q6: How should the commission be looking to develop the UK's capability in Earth observation data, both technologically and to support an effective market?

RoS is interested in how developments here can support its operational activities, e.g., for validating ownership boundaries.

Some points to note include:

- Time series data would also potentially add value.
- Release should be under clear licencing frameworks that facilitate reuse.
- Land-use dictionaries and mappings would need to be maintained.
- Workflow processing engines should be developed
- Spectral libraries would be required.
- Automated change detection at a variety of granularities (e.g., urban/rural)

Q7. Which new technologies should the commission focus on to provide new opportunities to process and exploit geospatial data for economic growth?

RoS has no wish to predefine technologies. Our focus is on developing and harnessing our data to maximise public value, and we maintain a technologically-neutral stance in order to best support and stimulate innovation.

However, some elements of the infrastructure would be supportive to support data-driven economic activity and growth:

- *Licence management technology* (licence calculus). It is inevitable that new products and services will conflate multiple data. The data sets may run into the thousands. These data will be released under different licence conditions that will affect how downstream products can be created, exploited and licensed. Currently the management of such processes is not transparent. This makes it difficult for licence holders to levy appropriate re-use fees and to ensure that product derivatives are being used in ways that comply to all the licence constraints demanded by the upstream data files (for example a product put out for sale may incorporate aspects of a data-set with a 'non-commercial' licence clause). Such an application will facilitate pass-through data charging to licence holders and increase credibility and provenance of re-useable data.
- Further research into and exploitation of *3D topological techniques* (moving beyond BIM) should be encouraged. This would allow the improved representation of geological stratigraphy, near surface infrastructure (pipes, cables etc.) and facilitate improved thermal modelling at a local and regional scale. From a conceptual level it would build a bridge between 2D and 3D concepts (such as an address UPRN and a valuation office hereditament: there is clearly a close conceptual relationship between the two – but this breaks down in terms of the data models).

Q8. How can geospatial data and applications be used to support enhanced roll-out of future technologies?

See above.

Geovation could unlock the potential for future technologies through supported access to Geospatial data and incubation of innovative start-ups working in known or unknown future technologies.

Q9: What are the options for how public sector organisations could continue to invest in maintaining and enhancing our geospatial data assets?

Business models need to enable opportunities for down-stream users to gain value from the data, while also supporting the sustainable and and up-to-date development of the geospatial assets that they hold. High quality, accessible data requires resourcing for investment and management to enable re-use.

RoS operates as a trading fund and so is entirely self-funded, reliant on the income from fees charged to meet the costs of the services it provides.

Whilst individual organisations such as RoS have a strong desire to innovate, clearly there are linkages to be managed between organisations through data consumption chains (e.g., for us, in respect of some of the data workflows we share with the Ordnance Survey and Map Base Maintenance). Strong coordination (e.g., across local authorities, to ensure consistent approaches) and partnership working will be essential to ensure concerted efforts to develop and invest and so lever genuine economic and social value.

Q10: What areas of the underpinning geospatial infrastructure such as positioning technologies, including GPS and indoor positioning systems, and geodetic networks and frameworks to support them, should we be prioritising the development of, in order to support the emerging requirements for geospatial data?

Data provenance is essential for any data source to have value. Metadata that reflects such provenance would greatly enhance the fitness-for-purpose of any re-use process.

The data collection and support frameworks mentioned above are all critical. In addition there are the data exposure and re-use frameworks. Improved access to co-ordinated repositories which can expose metadata (to facilitate discovery and re-use) and data streams (to facilitate realtime chaining). Co-ordinated repositories will also allow increased access to ‘restricted’ data during emergency response scenarios.

Q11: What role should the private sector have in both the development and maintenance of the underpinning infrastructure and enhancing the UK’s geospatial data assets?

RoS is agnostic with regard to the balance between public and private sectors, if appropriate management frameworks are in place to safeguard against risks of reduced data quality and accessibility (e.g., in relation to licensing, to mitigate risks around inhibitions to re-use).

Partnership approaches, properly established on a clear footing, have merit, to lever the benefits each sector can bring, in relation to expertise, capacity and agility as well as governance and regulatory assurance. A significant challenge lies in upskilling the public sector, and clearly there are considerable synergies to lever.

Q12. Do you face challenges when working with geospatial data from across the public sector? If so, what are they and how could value be better released? Are there any technical remedies or standards that could be adopted to improve the interoperability of geospatial data? Please provide supporting evidence of what these remedies could help to accomplish.

Challenges relate to:

- Standards to improve consumption / interoperability
- Formats – from non-proprietary re-useable formats (csv etc.) to self documenting formats (xml, json, rdf)
- Vocabularies (internal, domain agreed and persistent)
- Licensing, which is essential to facilitating unambiguous re-use

These aspects of spatial data are all essential to resolve, and technically-feasible solutions could be found. However, the will to find and coordinate cross-organisational capacity is the fundamental challenge.
Challenges relating to making available data within ScotLIS are consistent within question four. Quality and update frequencies are issues, including the level at which some of the data is mapped at. We would benefit from investment within some local authority data sets to improve their viability for inclusion with the land information service.

Where data is made available within new initiatives e.g. digital planning, it should be interoperable and available to others for inclusion.

Q13. How can the Geospatial Commission act as a more effective customer for geospatial data on behalf of the public sector?

The Geospatial Commission could play a useful role in relation to championing licensing developments to facilitate unambiguous re-use of data.

Like many government organisations, RoS is examining ways in which the data and services it manages can have greater societal impact beyond the core legal conveyancing remit through open and commercial service streams. Some of this is a response to the transparency agendas promoted by national governments (open data) and the European Union (INSPIRE) designed to increase stakeholder access to national data and to catalyse the 'knowledge economy'. This means the derivation of new data products and services. Some of these products and services could be accessed under commercial licences which would provide alternative income streams.

Licences will be produced on a product by product basis and, wherever possible, are likely to be based on standard licences (i.e., Government or Creative Commons licences). Clearly, when any of these data products re-use content provided by the OS then any downstream product and licence must be compliant with any upstream licence. In this regard the current OS licence poses challenges.

Protection through licensing conditions by OS of the intellectual property inherent in its data is appropriate given the quality and investment in the products. However, the suite of licensing models is complex, making it difficult to determine what can and cannot be done with any resultant derived or conflated data product. The spatial description of rights in the Land Registry system is heavily reliant on OS IP; hence, the terms associated with OS licences are crucial to RoS data derivations. Full clarity is needed surrounding rights to re-use data, maximise impact and commercialise data products.

Q14. Are there any additional geospatial datasets, from the other partner bodies or other sources, that the public sector would derive significant benefit from having access to, that might have novel and valuable use cases? What would that access look like?

As noted above, data provenance is key to harnessing value through re-use.

Planning data is of considerable interest across the economy. Digital planning is highly symbiotic with RoS public task work (e.g., with regard to change intelligence for workflow etc) and partnership working around this could create significant public benefit.

Q15: How can we best ensure effective local authority coordination and sharing of best practise, using location data to better deliver public services?

Consistency across local authorities is a key issue.

In Scotland, Digital Office activity is supporting this aspiration. In Scotland, the Local Authority Digital Office activity is one channel supporting this aspiration. Through potential collaboration with OS on Geovation effective Local Authority collaboration could be achieved.

Q16: As a result of this analysis, we are prioritising the exploration of possible initiatives in the high-value categories identified:

- **property and land**
- **infrastructure and construction**
- **mobility**
- **natural resources**
- **sales and marketing**

What are the existing or potential geospatial applications which could be scaled-up or developed in order to capture economic value? (We would particularly welcome responses from industry and other bodies engaged in these sectors.)

In October 2017, RoS launched ScotLIS our land and property information servicel, in public beta. As well as surfacing our registration data, this evolving platform will provide considerable potential for a range of other applications to add social and economic value.

RoS launched Scotland's Land Information Service (ScotLIS) into public beta. It provides a wealth of information on land and its ownership, with plans to improve on this over time. Its aspiration is to add 3rd party data where it augments data already available, and provides value to users.

With the correct investment in 3rd party data to improve its quality, it would be possible to include this at a larger scale and ensure there is trust in its accuracy – one of the bigger blockers to progression at the moment. It would result in property searches being more informed, and easier to conduct.

It is also possible to combine both 1st and 3rd party land and property information with digital planning, and other possible sources – for example; allowing users to understand whether planning applications have been submitted a given property and who owns it.

Planning data is of considerable interest across the economy. Digital planning is highly symbiotic with RoS public task work (e.g., with regard to change intelligence for workflow etc) and partnership working around this could create significant public benefit.

Planning data is of considerable interest across the economy. Digital planning is highly symbiotic with RoS public task work (e.g., with regard to change intelligence for workflow etc) and partnership working around this could create significant public benefit.

The ScotLIS Roadmap is available online for all to see, and the public service can be accessed via https://scotlis.ros.gov.uk/.

Q17: Are there any other areas that we should look at as a priority?

Q18: What are the main potential private and public sector innovations that will rely on the use of geospatial data to rollout, and are there corresponding regulatory challenges?

Q19: How best can we make the UK's presence in the international geospatial world more visible?

Clearly, in an ever more interlinked globalised world, engagement with international interests will be key, e.g., to ensure appropriate standards are chosen for frameworks.

RoS is an active participant in a range of international fora, including the Registrars of Title Conference, the Federation Internationale Geographique (FIG) and Eurographics.

Q20: Where should the UK be looking for points of comparison overseas? Who are the other international exemplars? What best practice is being modelled overseas that we can learn from?

RoS has found useful frameworks and comparators in Land Administration via ISO standards such as LADM ISO 19152. RoS has also drawn thinking from the New Zealand and Dutch cadastres as well as from Norway, Sweden and Estonia.

Thank you for your time in completing your response to our call for evidence.

Any questions, please get in touch with the Geospatial Commission via geospatialcommission@cabinetoffice.gov.uk

Call for evidence - three key themes

We have identified three high-level themes that could help our approach to setting a strategy which are as follows:

1. Supporting innovation in the geospatial sector, exploring how to secure

cutting edge skills, the right access to data, and opportunities from emerging technologies for the geospatial sector itself

2. Enhancing the UK's geospatial assets, looking at how best to align

interests, avoid duplication, and instill best practice across the whole public sector

3. Driving investment and productivity in geospatial applications, asking in which wider sectors the most value lies from better exploitation and use of geospatial data, in the UK and internationally

Our questions

Q1. Is our view of the geospatial data types accurate? If not, what should be included or excluded from this?

No comment.

Q2. In addition to current government policy, what are the areas of geospatial skills where the commission could best focus, to help ensure the necessary capability within the UK for the future?

a. Data Science / Big Data

The growing availability of real-time sensor (IoT) data and its potential to reveal valuable insights means that GI professionals also need to develop their skills handling Big Data, e.g. Data Science skills. It is very uncommon for GI professionals currently to be familiar with and using big data technologies. Whereas other Data Science industries (e.g. data analytics) are moving towards GI and pragmatically solving challenges in new ways, potentially making applied GI work increasingly obsolete. Missing this opportunity may mean that the scope of geospatial is more limited to niche analytics of refined, structured data, rather than the discipline getting involved closer to data creation. These other industries and disciplines are developing faster than GI, e.g. Business Intelligence (BI)/Data Analytics (DA). GI professionals are used to structured data warehouses and Extract, Transform, Load (ETL) workflows, but these don't scale well to Big Data volumes, velocity and variety. Developing skills in noSQL, search technologies, batch and stream processing, etc will bring GIS closer to the forefront, rather than becoming a niche discipline for specialist work.

b. Convergence

There is a need for GI professionals to develop their skills in Data Analytics and Business Intelligence. These industries are much larger, evolving more rapidly and building geospatial capabilities themselves. Typical GI skills in data manipulation and cartography transfer well into DA/BI, including designing visualisations (beyond just maps). Typical data-driven managers (in areas I'm familiar with) increasingly want simple, fast visualisation of data, not complex, in-depth analysis. For example hotspot/heatmaps – latest generation BI tools (e.g. Tableau) make this a single button transformation, not a detailed scientific decision to assess the best interpolation algorithm. GI needs to move towards BI/DA, sharing knowledge and building common skills. Knowledge share will also lower the barrier to entry into GI for those that wish to specialise in the geography. c. Links with Academia

GI professionals, particularly working in government could benefit from professional development in collaboration with academia. For example, Surrey County Council worked with Surrey University Business School to build digital transformation skills and familiarity with emerging technologies. Massively Open Online Courses (MOOC) are commonplace now and cover necessary topics. Discounted enrolment could be offered to public sector analysts.

Q3. What are the geospatial skills needs and gaps in your organisations, how can these be most effectively addressed, and how can careers in the sector be best promoted?

a. Information Governance Confidence

GI professionals have potential to be the gateway between a wealth of valuable data sources (many of which they've got domain knowledge on and have imported into spatial data warehouses). Uncertainty around the law, policies and ethics of data sharing, processing, aggregation, analysis can discourage use of some data, stifling value generation. Solution: Work with professional bodies in the IG space to offer incentivised training opportunities for GI staff, particularly those in government roles. Formation of local support networks for GI professionals to ask questions of IG specialists (i.e. former Centre Excellence Info Sharing). Sharing best practise, including identification of typical safe gateways with which to process certain data (e.g. mobile phone activity data, vehicle movements, open data publications, etc). b. Data Science

Councils have significant opportunity to improve services and outcomes by better exploiting their data and emerging technologies, including less traditional data sources (e.g. real-time IoT sensor data, drone survey data, telemetry - route optimisation for ambulances, bin lorries, gritters, Special Educational Needs (SEN) journeys...). Currently local government (including us) do not widely possess the skills to exploit this

data and either suffers or pays consultants. We are also not factoring these technological and societal changes into our forward plans and service strategies, due to an unfamiliarity of the potential. GI professionals are well placed however to seize this opportunity, through focussed professional development. Recent ‘Buses Bill’ just one example –local government isn’t ready to exploit this new data and improve public transport / ease congestion. Solution: Work with academia to design short, flexible, [MOOC] courses to develop data science skills. Encourage tailored courses at discounted rates via AGI accreditation. Centre of excellence and secondment opportunities to encourage knowledge sharing and foster networked behaviours. Promote careers to students via academia links. GI needs to be more visionary, encouraging us all to embrace newer technologies. c. Data Analytics / Business Intelligence

We need to visualise data in many other ways, not just the geographical dimension. This would be done with BI/DA tooling, in what is a rapidly growing and maturing market. Solution: Open up GI knowledge to other areas – those in BI/DA struggle to embrace complex address data schemas, projected spatial data, for example. Promote GI careers also, to those that want to specialise. d. Free, Open Source, Community Mappers

Supporting the voluntary work of community mappers is valuable and could encourage more to enter the industry. Extra support to local authorities in address change intelligence would be valuable. Solution: OSM Mapper in Residence scheme

Q4. Are there any publicly or privately-held geospatial datasets that are currently challenging to access or use or of insufficient quality, but which you or your organisation would find valuable if these issues could be resolved? Please explain why this would be of value, and how access/quality could be improved?

a. Address lookup web service

GI professionals waste time finding, downloading, transforming and maintaining duplicate address and other core reference datasets. We want quick, reliable, cloud-hosted web services of these core things to use on a commodity basis within digital services and back office systems. The Surrey GIS Forum pioneered this some years ago with their AddressBase API, developed from a GDS origin. This is available freely to any PSMA clients, and currently used in tens of local authorities. Chargeable alternatives include OS Places. Solution: Include OS Places or equivalent address web service within PSMA. b. Planning data

For councils and society at large it is hard to find planning information. This varies across boundaries and organisations, in terms of responsibility, format, accessibility, local conventions/interpretation and is quite frankly out of touch with modern society’s needs (e.g. notices on lampposts!). Significant efficiency gains internally and externally from better data curation and sharing. Solution: The Surrey GIS Forum have done discovery and prototyping work as well as lobbying (survey results available on

request). Including building a prototype Planning Hub using BIS Data Strategy ‘breakthrough funding’. LGA launched Incentive Scheme followed. Current blockers for full commercial use of this data due to OS derived data rights. Consumers such as Land App and Land Insight. Regional/national scale-up. c. OS large scale basemap cloud service

Core reference data that gets locally downloaded, processed and managed unnecessarily hundreds of times in duplicate, when most simply need the latest data running in their web and back-office systems. Many of us pay for cloud tile services, which could be improved upon via centralised procurement. Solution: Access to hosted data included in PSMA. d. Land Registry title details

Full textural attribute data for Land Registry titles would save time and improve quality of local decisions. Currently we need to pay to reveal full detail, despite title parcel geometries being available under INSPIRE. Solution: Access to data included in PSMA. Potentially reconsider as part of any Land Charges and Land Registry re-design.

Q5: Do you anticipate that any changes will be needed to the both address data and the wider address ecosystem, to support emerging technologies? Please provide evidence of value to support any proposed changes.

a. Pace of address data maintenance

Increasing pace of digital transactions and public expectations for immediate service delivery (alongside any open data release of NLPG) will require LLPG Custodians and Street Naming officers to work in a more coordinated and timely fashion, as well as central validation/refinement to be faster (e.g. addressbase 6 week cycle). Solution: Central maintenance of BS7666 LLPG data! Deeper integration between main address databases / organisations, including at a local level, where Planning, Council Tax, Elections, Refuse and other services can be vital indicators of address intelligence for LLPG custodians. Use of additional data sources (inc commercial) to help maintain LLPGs – especially anything to improve commercial address quality. b. UPRNs made open

Releasing the [postal] address textural string may be insurmountable, but releasing the UPRN will still allow better machine to machine exchange of address data, realising efficiencies. Solution: Release of UPRNs and spatial coordinates as open data.

Q6: How should the commission be looking to develop the UK’s capability in Earth observation data, both technologically and to support an effective market?

No comment

Q7. Which new technologies should the commission focus on to provide new opportunities to process and exploit geospatial data for economic growth?

a. Emerging technologies

See Gartner Hype Cycle, including 2018 version. Virtual, mixed and augmented reality all have significant reliance on geospatial data, as do many other pre-consumerised technologies shown. Many of these technologies will mature in the time period of the average council's corporate plan, yet are not considered deeply enough (despite representing significant disruptive forces). Obvious priority areas would be mixed reality, autonomous vehicles, drones, IoT platforms and 5G. With a growing amount of instruments and sensors within personal transport, government should be considering the data infrastructures necessary to exploit this. For example – crowd-sourced road condition surveys, real-time route optimisation, etc. Solution: Involvement with academia, government-funded research labs and leading commercial organisations to explore opportunities to incorporate more geospatial data into emerging technologies. Discovery and prototyping. Centre of excellence / collaboration in existing (e.g. electric vehicles – transport research laboratory). b. Current [underexploited] technologies

Some current technologies have potential to benefit from increased use of geospatial data, including voice control/assistance / augmented reality, drones. Voice is mature in consumer artificial intelligence offerings like Siri, Alexa, Cortana, but geospatial data is not available or presented well enough for full exploitation. Obvious examples would be for integrations to be deployed to facilitate access to public services, dependent on location and personal circumstances. Solution: Data needs to be refined, published and integrated, ideally in a coordinated way across the sector. See Google dataset search for example of how public data can be surfaced and integrated into services like google (thus Assistant). GI needs to converge around popular technologies at least to demonstrate potential.

Q8. How can geospatial data and applications be used to support enhanced roll-out of future technologies?

a. Data infrastructure (visionary)

A robust data infrastructure hosting core reference data and brokering the exchange of data across and between sectors. Getting involved in this now to prevent being left behind by technological pace of development and potential commercialisation / vendor locks. Example include smart vehicles - supported by data standards and aligned with vehicle tax and other databases and income streams. Vehicle sensor data collection – could all vehicles deliver data about road condition to a central repository, regardless of vehicle manufacturer, specification and age. This will be made possible with 5G and increasing IoT sensor technologies. Solution: Engage with technology disruptors and

leaders, academia and others to shape thoughts and design prototypes. b. Data infrastructure

Central repository of core reference data and web services to ease access to

reliable, authoritative geospatial data, primarily within the public sector. Remove duplicated processes of obtaining, transforming, loading and hosting data. Solution: Establish central data repository, web services, etc. Work with Open Data Institute (ODI) to build 'open' best practise into solution.

Q9: What are the options for how public sector organisations could continue to invest in maintaining and enhancing our geospatial data assets?

a. Crowd-source

Local-level partnerships with Open Street Map (OSM) community to input change intelligence information into local authorities. E.g. OSM Mapper in Residence scheme. Better coordination between volunteers, local authority and Ordnance Survey to capture address and topographical changes and share without friction. Likewise, open data may offer an element of third-party inspection and correction of data, where many eyes and alternative uses can reveal errors. Finally, open data can foster new tools and applications for use within the public sector, such as Spend Network, who worked with Surrey County Council to hone open data publications in exchange for sharing knowledge on visualisation best practise, with resultant improvements to internal data analysis. b. Open Source

Contribute to development of free, open source GIS software (e.g. qGIS), making it an increasingly viable alternative to proprietary vendors. Cashable savings and development of common skills base and support network. c. Central data infrastructure

Reap local-level efficiency savings by offering core reference data from a central source, avoiding huge duplication effort among GI data administrators. d. Central address maintenance

Whilst a much-debated and explored topic, this is one that could yield local savings and facilitate a more punctual and less resource-intensive compilation of the national address gazetteer. Presumably plenty of costs and concerns elsewhere with this proposal however.

Q10: What areas of the underpinning geospatial infrastructure such as positioning technologies, including GPS and indoor positioning systems, and geodetic networks and frameworks to support them, should we be prioritising the development of, in order to support the emerging requirements for geospatial data?

a. Standards

INSPIRE, BS7666, OGC, Gemini, XML, ESD (LGA). Encourage use of standards, to ensure they reap value. Especially those applicable to the public sector where this could reduce data exchange friction. Local Government Association ESD standards list is a comprehensive and powerful list of services, functions, powers, duties and more. Complete with linked data Unique Resource Identifiers (URI), this can allow datasets to be collected and combined for greater insight.

Q11: What role should the private sector have in both the development and maintenance of the underpinning infrastructure and enhancing the UK's geospatial data assets?

a. Data marketplace

We should seek to create a data market / information economy whereby all sectors can contribute and consume. A valued underpinning digital infrastructure that is of value will need maintaining mutually. Whilst dated, the London City Data Strategy approached this in their 2016 document, focussing on the wider data spectrum, not just open data. Role for academia also, who also would want access to processed, administrative data for research purposes. Local/regional pilots, akin to ODI Node model. b. Standards

Co-author, use and maintain cross-sector open standards.

Q12. Do you face challenges when working with geospatial data from across the public sector? If so, what are they and how could value be better released? Are there any technical remedies or standards that could be adopted to improve the interoperability of geospatial data? Please provide supporting evidence of what these remedies could help to accomplish.

a. Fragmentation

In local government there is considerable variation in the way data of the same topic is produced, stored and shared (if at all). An example of this is planning application data which despite being fundamentally the same and delivering the same function, can differ considerably across administrative boundaries. Solution: Work like the Surrey Planning Hub to harmonise publication of planning data and make collective, value-added information available from a central web service, for any downstream use. Work in an open source environment to share knowledge and encourage widespread collaboration. Embrace common standards, such as those created by the LGA, iStandUK and others. Encourage and nurture coalition innovation groups like Surrey Digital Services, perhaps with more formal support like the Geovation model. b. Discovery & access

Other than local data observatories and open data syndicated onto data.gov.uk, there is no central portal/inventory where public sector organisations can share definitive data for others to access. Whether this is

snapshot data for download, or access to live web services. Solution: Encourage further publication of data onto data.gov.uk (DGUk), including OGC web services (WMS/WFS). For licensed or more sensitive data consider enhancing DGUk to host these datasets for authorised users (perhaps similar to http://environment.data.gov.uk/ds/catalogue/#/catalogue). Pursue INSPIRE-type roadmap of discovery, view and download services, as well as data schema harmonisation. Develop data inventory concept used in linked data principles and by some open data publishers. A firm enough, sustained push, alongside provision of tooling / central hosting will see local government conform. Ongoing compliance linked with PSMA licensing and/or improvement schedule approach. c. Data sharing agreements

Local government GIS officers can lose time preparing bespoke data sharing agreements for regularly requested data. Equally, end users/requesters don't want to be concerned by government boundaries or varying licences. Solution: Standardise popular data sharing agreements, like the PSMA does. Create a tool to allow pick-list based customisation of standard agreements, building the legal text behind the scenes based on user selections. Align with data sharing services like Emapsite's Contractor Portal, such that data access can then be granted, without burden of extracting, packaging and distributing data.

Q13. How can the Geospatial Commission act as a more effective customer for geospatial data on behalf of the public sector?

No comment.

Q14. Are there any additional geospatial datasets, from the other partner bodies or other sources, that the public sector would derive significant benefit from having access to, that might have novel and valuable use cases? What would that access look like?

a. Aerial imagery

More frequent surveys of visible light imagery, LIDAR and potentially oblique imagery. Uses for tens of local services, including planning, enforcement, countryside management and more. b. mData (aspirational)

Aspirationally speaking, it would be good to access mobile phone activity data, for a whole raft of reasons to support our service planning and delivery. Raw data is well into the Big Data definition however, so skills are not yet mature enough in our sector to analyse the data ourselves, hence access would be more a case of consuming off-the-shelf insight reports, perhaps about migratory patterns into major towns, etc. Experimental, discovery work.

Q15: How can we best develop a single UK strategy, ensuring alignment between the individual strategies across the UK while still allwoing for regional variations?

No comment.

Q16: How can we best ensure effective local authority coordination and sharing of best practise, using location data to better deliver public services?

a. Industry groups/bodies

Industry groups like the LGA and AGI have been useful in encouraging change and compliance across local gov, for example with open data (incentive scheme, transparency code) and INSPIRE initiatives. LGA incentive scheme successfully created hundreds of open data publications from local government, essentially overcoming many of the initial steps with sharing data effectively. Online KnowledgeHub remains a useful networking and peer- support tool. b. Local area peer groups & liaisons

To convene regional meetings and bring together those working in the same field. Including those specifically looking to drive transformation – e.g. Surrey Digital Services. Potentially widen scope of meetings into something resembling the ODI Node structure, allowing greater sharing of skills and knowledge. Accommodate and encourage academia. Forum for officers to share experiences and avoid common pitfalls. Incentivise collaborative work to conduct work over multiple authorities rather than singularly at greater overall expense – e.g. waste round route-optimisation. Support LocalGovDigital, including LocalGovCamp. c. Alignment

In terms of helping compliance with any newly proposed initiatives, alignment with existing regulation/directive tasks like INSPIRE, BS7666, Census may help as most authorities are committed to these. d. Common tools

Greater coordination can be encouraged by providing consistency in the way things are done – i.e. central address maintenance, web services, open data publication, metadata, etc.

Q17: As a result of this analysis, we are prioritising the exploration of possible initiatives in the high-value categories identified:

- **property and land**
- **infrastructure and construction**
- **mobility**
- **natural resources**
- **sales and marketing**

What are the existing or potential geospatial applications which could be scaled-up or developed in order to capture economic value? (We would particularly welcome responses from industry and other bodies engaged in these sectors.)

a. Planning Hub

The Surrey GIS Forum's prototype planning data aggregator was hindered by OS derived data rights, preventing release under OGL and thus consumption by the land and property industry. LGA evaluation report. Astun Technology case study. iStandUK 2016 award. Developing this further in an environment without such restraints, adding spatial extents, more attribute data, improved address/location details (e.g. UPRN) would significantly increase downstream benefits. Other authorities have pursued this, including Hampshire and Hackney. Opportunities to align interests of public and private, for example, planners, land charges, contaminated land, surveyors, land owners, builders, etc. As startups Land App and Land Insight are proving. b. SDS AddressBase API

The Surrey GIS Forum created a nationwide OS AddressBase Premium lookup accessible by any PSMA customer. This satisfies a widespread need among councils for simple, fast address lookups in their web applications. Applications of this nature could be scaled up, at least within the public sector / PSMA community.

Q18: Are there any other areas that we should look at as a priority?

No comment.

Q19: What are the main potential private and public sector innovations that will rely on the use of geospatial data to rollout, and are there corresponding regulatory challenges?

a. Next gen personal transport

Growth of electric cars is necessitating more intelligent journey planning to factor in necessary and convenient stops (tailored to driver's preferences). Accurate and real-time geo data required, for example on congestion, charger availability, nearby services, etc. Autonomous cars clearly a whole level deeper in terms of geo data required. b. Oyster-style public transport outside London

Buses Bill facilitates sharing of commissioned transport provider telemetry data which will require a [geo]data infrastructure to gather, consume and publish for innovations like CityMapper to florish. Significant citizen benefits and potential government commissioning improvements. c. Google dataset search

Not strictly an innovation in its own right but surfacing well curated datasets through google and thus allowing their integration with machine-based

processes will facilitate a lot of potential innovations. d. Dynamic location service delivery

e.g. Delivery of parcels to individuals based on their current / forecast location, relying on a more granular location/address framework. Probably reliant on machine interpretation of 'address'/location data, not traditional address string. (whatthreewords, UPRN+X/Y coordinates). Like Volvo's connected cars development. e. Centralised Land Charges service

Basic data housekeeping and sharing between central and local government. Opportunity to conduct discovery work / observe challenges.

Q20: How best can we make the UK's presence in the international geospatial world more visible?

a. Open source (FOSS4G, OSM)

Support open source software and mapping. Invest in the development of common tools for anyone to use.

Q21: Where should the UK be looking for points of comparison overseas? Who are the other international exemplars? What best practice is being modelled overseas that we can learn from?

No comment.

Thank you for your time in completing your response to our call for evidence.

Any questions, please get in touch with the Geospatial Commission via geospatialcommission@cabinetoffice.gov.uk

Geospatial Commission: Call For Evidence Response Questionnaire

Please submit your completed questionnaire to:

geospatialcommission@cabinetoffice.gov.uk.

Clearly title your email *'Call for evidence response'*.

About you and your organisation

Name	[Text redacted]
Organisation	Royal Botanic Gardens Kew
Job title	[Text redacted]
Address	[Text redacted]
E-mail	[Text redacted]
Telephone	[Text redacted]

Please select which of the following best describes you as a respondent:

Respondent	**Please mark with a X**
Academic	
Business representative / trade body

Charity or social enterprise	x
Individual	
Legal representative	
Local government	
Large business (over 250 staff)	
Medium business (50 to 250)	
Small business (10 to 49)	
Micro business (up to 9)	
Other - please state	

Call for evidence - three key themes

We have identified three high-level themes that could help our approach to setting a strategy which are as follows:

1. **Supporting innovation in the geospatial sector**, exploring how to secure cutting edge skills, the right access to data, and opportunities from emerging technologies for the geospatial sector itself
2. **Enhancing the UK's geospatial assets,** looking at how best to align interests, avoid duplication, and instill best practice across the whole public sector
3. **Driving investment and productivity in geospatial applications**, asking in which wider sectors the most value lies from better exploitation and use of geospatial data, in the UK and internationally

Our questions

Q1. Is our view of the geospatial data types accurate? If not, what should be included or excluded from this?

A level of education about the value and use of Geospatial data needs to be added to one of these themes.

Q2. In addition to current government policy, what are the areas of geospatial skills where the commission could best focus, to help ensure the necessary capability within the UK for the future?

Q3. What are the geospatial skills needs and gaps in your organisations, how can these be most effectively addressed, and how can careers in the sector be best promoted?

We work on the imaging and research side of the industry and there is no shortage of interest and suitable candidates for our posititions, but unfortunately we can not offer commercial salaries.

Graduates other than PhD students seem to lack the experience that we need, and we have instead started to offer internships for small research areas.

Q4. Are there any publicly or privately-held geospatial datasets that are currently challenging to access or use or of insufficient quality, but which you or your organisation would find valuable if these issues could be resolved? Please explain why this would be of value, and how access/quality could be improved?

High resolution satellite imagery is always of benefit to our work, but comes at a steep price. WV2 is our most purchased resource, but few projects can afford the data.

We now use drone data a lot more, but there are no Civil Service resources for Geospatial training or drone pilot course of which I am aware, and commercially they are prohibitively expensive.

Q5: Do you anticipate that any changes will be needed to the both address data and the wider address ecosystem, to support emerging technologies? Please provide evidence of value to support any proposed changes.

Q6: How should the commission be looking to develop the UK's capability in Earth observation data, both technologically and to support an effective market?

Providing greater free access to high resolution datasets.
Sharing of free data that has UAV collected, or processed.
Sharing expertise in newer innovations.

Q7. Which new technologies should the commission focus on to provide new opportunities to process and exploit geospatial data for economic growth?

Access to drone share imagery or products

Q8. How can geospatial data and applications be used to support enhanced roll-out of future technologies?

Q9: What are the options for how public sector organisations could continue to invest in maintaining and enhancing our geospatial data assets?

Q10: What areas of the underpinning geospatial infrastructure such as positioning technologies, including GPS and indoor positioning systems, and geodetic networks and frameworks to support them, should we be prioritising the development of, in order to support the emerging requirements for geospatial data?

Q11: What role should the private sector have in both the development and maintenance of the underpinning infrastructure and enhancing the UK's geospatial data assets?

Q12. Do you face challenges when working with geospatial data from across the public sector? If so, what are they and how could value be better released? Are there any technical remedies or standards that could be adopted to improve the interoperability of geospatial data? Please provide supporting evidence of what these remedies could help to accomplish.

Q13. How can the Geospatial Commission act as a more effective customer for geospatial data on behalf of the public sector?

Q14. Are there any additional geospatial datasets, from the other partner bodies or other sources, that the public sector would derive significant benefit from having access to, that might have novel and valuable use cases? What would that access look like?

Q15: How can we best ensure effective local authority coordination and sharing of best practise, using location data to better deliver public services?

Q16: As a result of this analysis, we are prioritising the exploration of possible initiatives in the high-value categories identified:

- **property and land**
- **infrastructure and construction**
- **mobility**
- **natural resources**
- **sales and marketing**

What are the existing or potential geospatial applications which could be scaled-up or developed in order to capture economic value? (We would particularly welcome responses from industry and other bodies engaged in these sectors.)

Q17: Are there any other areas that we should look at as a priority?

Q18: What are the main potential private and public sector innovations that will rely on the use of geospatial data to rollout, and are there corresponding regulatory challenges?

Q19: How best can we make the UK's presence in the international geospatial world more visible?

Q20: Where should the UK be looking for points of comparison overseas? Who are the other international exemplars? What best practice is being modelled overseas that we can learn from?

Call for evidence - three key themes

We have identified three high-level themes that could help our approach to setting a strategy which are as follows:

1. **Supporting innovation in the geospatial sector**, exploring how to secure cutting edge skills, the right access to data, and opportunities from emerging technologies for the geospatial sector itself
2. **Enhancing the UK's geospatial assets,** looking at how best to align interests, avoid duplication, and instill best practice across the whole public sector
3. **Driving investment and productivity in geospatial applications**, asking in which wider sectors the most value lies from better exploitation and use of geospatial data, in the UK and internationally

Our questions

Q1. Is our view of the geospatial data types accurate? If not, what should be included or excluded from this?

Q2. In addition to current government policy, what are the areas of geospatial skills where the commission could best focus, to help ensure the necessary capability within the UK for the future?

The Quantitative Methods Research Group (QMRG) was founded in the 1960s as a branch of the RGS-IBG, with the aim of furthering research and education in all aspects of quantitative and computer methods in Geography. This aim still stands, albeit now focussed increasingly on research and education in the geospatial data analysis and geographic data science. The current QMRG committee consists of academics (who are also RGS-IBG fellows) elected from an array of British universities, including instutions having a long-standing reputation nationally and internationally for quantitative geography and geographic data science. Currently there are around 200 member of the QMRG across all career levels from postgraduate level upwards, and the Committee has sought input from QMRG members to inform this response. Given the aforementioned focus of the QMRG at the education/research axis, plus the time available to the Committee to make this response, the focus of this response is limited to only the first theme on 'supporting innovation', and specifically to Questions 2 and 3 in the Questionnaire. However opportunities to engage in other themes/questions would be welcomed by the QMRG Committee.

Question 2 in the Consultation regards steps that could be taken now in order to ensure that geospatial skills are developed into the future. For the QMRG Committee this is fundamentally a question about teaching and learning, and linking up to opportunities to develop interests in geospatial knowledge and skills across all educational levels. Specifically, and reflecting the QMRG's position as part of the RGS-IBG, we see huge value in promoting these opportunities through the subject of Geography, not just at university level, but also at pre-University and postgraduate levels. Geography as a study of people, places and our planet should be an exciting subject for learners, and we have observed through our own teaching practices the ways in which education in Geography can ignite interest in more advanced and complex forms of geospatial analysis. In our view Geography is better placed to kindle such interest than courses which have a heavier mathematical or computational focus. However, while we can point to some cutting edge courses and practice that fulfil these demands and expectations, among our own and other institutions, we are also increasingly concerned about recent changes to Geography's position in the British education systems. Although the numbers of students entered to A-level Geography increased slightly over the past five years, last year saw a decrease in entries, in part associated with the 'de-coupling' of the Geography A level from the AS-level in England, with Geography slipping to become the 10th most studied A-level, entries being down by 8% compared to the previous year. In other parts of the UK the situation is even more challenging, as in Wales and Northern Ireland there have been year on year decreases in the number of students entered to A-level Geography since 2015 (see https://results.ffteducationdatalab.org.uk/a-level/geography.php), while in Scotland the Royal Scottish Geographical Society has expressed concerns that the move to the Scottish 'Curriculum for Excellence' (among other factors) is leading to a narrowing of school curricula, in turn posing a threat to the numbers of Scottish-system pupils choosing to do Geography. Overall this picture raises concerns about a potentially diminishing status and profile of Geography in our education systems, and our concern from this is the reduced numbers who may consider Geography at university or postgraduate levels. If we see such reductions occurring, then in turn this may also impact on the upskilling new

generations of learners able to spearhead and advance the geospatial revolution. We would therefore advise the Commission to pay heed to the aforementioned changes and to consider ways to mitigate their potential negative impacts. The RGS-IBG has done further assessment in this area, including recommendations to the A-level Content Advisory Board in 2014 regarding greater integration of quantitative methods into the A-level curriculum, and more recently its 'Data Skills in Geography project'.

Secondly and on a more specific point, we were uncertain about what is being referred to by 'current government policy' in the associated section in the Call for Evidence document (page 13). While the section constain an outline of a few useful ways in which geospatial skills acquistition may be promoted and enhanced, these are suggestive only, and as such could not rightfully be labelled as 'policy'. It would be helpful therefore if this reference to policy could be clarified.

Q3. What are the geospatial skills needs and gaps in your organisations, how can these be most effectively addressed, and how can careers in the sector be best promoted?

As noted above the QMRG is most associated with university-level Geography departments and programmes. Most Geography departments in the UK will include at least one course introducing quantitative methods within the Geography degrees they offer, and likewise, many departments now provide an at least an introduction to GIS, with GIS also noted in the Consultation document as being one of the main avenues into the geospatial sector. Some universities, a relatively small handful, offer specific undergraduate degrees in GIS, although more commonly GIS is included as one element among others within Geography degrees. A small number of universities also offer GIS as a taught postgraduate Masters' level degree, typically of a year's duration.

The QMRG committee members have experience teaching courses in quantitative geography and GIS across all the type of degree structures just outlined, and the following obervations stem from that experience.

One area of need is not a skills one and rather is more of a perceptual matter – namely to counter the possibility that 'geospatial' is simply seen as another name for 'doing maths' in Geography. This sort of criticism has previously been levelled against quantitative geography, and is untrue. In our view, the opportunites for advancing geospatial skills are because the geospatial arena sits across multiple intersections – between geography, GIS, maths, statistics and computer science, but also between different bodies of geographical theory and scientific knowledge, and other fields including information communication, design and even elements of narrative and story telling. Accordingly we urge the Commission to take a broad view in supporting the promotion of opportunities in the geospatial arena in the widest sense, to lessen the chances of stifling new innovative and intersectional avenues.

However, having stated this preference for an 'intersectional' approach, we acknowledge it comes with challenges. For example, we have commonly observed that, among our students who opt to do GIS as part of their Geography degrees, a fair proportion of them lack confidence in methods of numerical analysis or are reluctant to engage in coding. Models of good practice and resources for teaching and learning at these intersections are now beginning to emerge, e.g. including books intended for texts such as the following:

Abernathy, D. (2016), *Using Geodata and Geolocation in the Social Sciences: Mapping our Connected World*. SAGE

Harris, R. (2016), *Quantitative Geography. The Basics*. SAGE.

Kitchin, R., Lauriault, T. and Wilson M., (2017), *Understanding Spatial Media*. SAGE.

Singleon, A., Spielman, S. and Folch, D. (2017), *Urban Analytics*. SAGE

However, more is needed to distill the ideas and topics beginning to be covered in texts such as these into a variety of different materials appropriate for teaching, learning and assessment.

Importantly too this should not be interpreted as a call to axe existing courses in quantitative methods or GIS, which rather should continue and in our view will in remain as key initial points of contact between learners and the geospatial arena. Rather, our call here is to find ways in which new geospatial courses and/or themes can be devised and implemented in harmony with those existing courses and within the constraints imposed by conventional degree structures and timetables. We would welcome the opportunity of working with the Commission on this, e.g. though convening of workshops.

Q4. Are there any publicly or privately-held geospatial datasets that are currently challenging to access or use or of insufficient quality, but which you or your organisation would find valuable if these issues could be resolved? Please explain why this would be of value, and how access/quality could be improved?

Q5: Do you anticipate that any changes will be needed to the both address data and the wider address ecosystem, to support emerging technologies? Please provide evidence of value to support any proposed changes.

Q6: How should the commission be looking to develop the UK's capability in Earth observation data, both technologically and to support an effective market?

Q7. Which new technologies should the commission focus on to provide new opportunities to process and exploit geospatial data for economic growth?

Q8. How can geospatial data and applications be used to support enhanced roll-out of future technologies?

Q9: What are the options for how public sector organisations could continue to invest in maintaining and enhancing our geospatial data assets?

Q10: What areas of the underpinning geospatial infrastructure such as positioning technologies, including GPS and indoor positioning systems, and geodetic networks and frameworks to support them, should we be prioritising the development of, in order to support the emerging requirements for geospatial data?

Q11: What role should the private sector have in both the development and maintenance of the underpinning infrastructure and enhancing the UK's geospatial data assets?

Q12. Do you face challenges when working with geospatial data from across the public sector? If so, what are they and how could value be better released? Are there any technical remedies or standards that could be adopted to improve the interoperability of geospatial data? Please provide supporting evidence of what these remedies could help to accomplish.

Q13. How can the Geospatial Commission act as a more effective customer for geospatial data on behalf of the public sector?

Q14. Are there any additional geospatial datasets, from the other partner bodies or other sources, that the public sector would derive significant benefit from having access to, that might have novel and valuable use cases? What would that access look like?

Q15: How can we best develop a single UK strategy, ensuring alignment between the individual strategies across the UK while still allwoing for regional variations?

Q16: How can we best ensure effective local authority coordination and sharing of best practise, using location data to better deliver public services?

Q17: As a result of this analysis, we are prioritising the exploration of possible initiatives in the high-value categories identified:

- **property and land**
- **infrastructure and construction**
- **mobility**
- **natural resources**
- **sales and marketing**

What are the existing or potential geospatial applications which could be scaled-up or developed in order to capture economic value? (We would particularly welcome responses from industry and other bodies engaged in these sectors.)

Q18: Are there any other areas that we should look at as a priority?

Q19: What are the main potential private and public sector innovations that will rely on the use of geospatial data to rollout, and are there corresponding regulatory challenges?

Q20: How best can we make the UK's presence in the international geospatial world more visible?

Q21: Where should the UK be looking for points of comparison overseas? Who are the other international exemplars? What best practice is being modelled overseas that we can learn from?

Call for evidence - three key themes

We have identified three high-level themes that could help our approach to setting a strategy which are as follows:

1. **Supporting innovation in the geospatial sector**, exploring how to secure cutting edge skills, the right access to data, and opportunities from emerging technologies for the geospatial sector itself
2. **Enhancing the UK's geospatial assets,** looking at how best to align interests, avoid duplication, and instill best practice across the whole public sector
3. **Driving investment and productivity in geospatial applications**, asking in which wider sectors the most value lies from better exploitation and use of geospatial data, in the UK and internationally

Our questions

Q1. Is our view of the geospatial data types accurate? If not, what should be included or excluded from this?

We encourage the commission to be inclusive as possible in the 'geospatial' data it considers from 'traditional' locational data, to Earth observation, to locational information (and potential) associated with administrative data, to crowd-sourced data, to data from the IoT etc. Standards, interoperability, versioning are key elements to the greater use, and value, of all of these.

Q2. In addition to current government policy, what are the areas of geospatial skills where the commission could best focus, to help ensure the necessary capability within the UK for the future?

Background

The Royal Geographical Society (with IBG) is the UK's learned society and professional body for geography. We are also a membership body with >16,500 Fellows and members. We work closely with geographers in schools, universities, and in professional practice setting standards (for the discipline and individuals), accrediting programmes and individuals (notably Chartered Geographer, with a specific stream in GI/GIS), delivering mentoring and training, and profiling careers and opportunities. We also advocate for the discipline, engage the public through an extensive and broad range of programmes, and are actively engaged in knowledge exchange activities across our communities.

We recognise there are many disciplines and professional bodies cultivating and developing this ecosystem of geospatial skills – from data science, to engineering, to design and beyond. All these all are critical. However, producing and consuming geospatial data intelligently, and interpreting it to unlock economic value and deliver social benefits, does require specialised skills. These skills

are needed not just by technical specialists but also (and critically) by decision-makers and consumers of geospatial data, analysis and insights.

Geography has and will continue to play a crucial role in the delivery of geospatial and broader geographical skills of interpretation and analyses. These core skills and competencies need to continue to be cultivated, supported and developed, embracing new technologies and approaches, and the ubiquity (and multiple sources) of spatial (geographic) information. We welcome opportunities to work with the Commission, and the geospatial and geographical communities broadly, to develop and signpost existing and new opportunities.

Our approach to this call for evidence

Our response focuses primarily on the opportunities, needs and gaps delivered through geography. In collating the evidence base to respond to the commission, we consulted our community (university academics, teachers in schools, research groups, professional geographers specifically); drew on our existing knowledge and activity in this area; reviewed published reports and online information about courses and training; analysed CPD returns of Chartered Geographers and consulted with them as employers and employees; and interviewed leading academics, in geography and beyond (business, engineering, data science).

In addition, we have also consulted, and worked with, the AGI with whom we have a strategic partnership and a programme of ongoing work, specifically focused on skills. Our insights are biased to the supply-side of skills and to geography (as noted above).

General comments

Attention and focus is needed at multiple levels, from schools through advanced research training, delivered in different formats to meet the needs of learners and professionals. Investment is needed in 'core' areas (such as geography, geomatics, surveying etc), but also new and emerging areas (including data science) and with different user communities (e.g. disaster response and risk management). Skills need to be developed not only for the creation, curation and assurance of geographic information, but also critically with the contextualisation, analysis, interpretation and use of this information. This is where geography – and its spatial lens - has a particular role to play.

We structure our response in terms of opportunities and intervention at different stages in the geospatial skills pipeline – schools, university level education, research and innovation, and professional practice. The evidence base is provided in the accompanying briefing document.

In schools

Foundational skills and awareness of the value of geospatial data and insights must start in the earliest stages of education in schools. Currently, core geospatial skills are delivered in UK schools almost exclusively through geography. Thus geography is a key vehicle to educate and inspire young people about geospatial broadly defined.

Revisions to the curriculum at KS3 (where geography is part of the statutory national curriculum in English schools and thus taken by all students), at GCSE (ca 250,000 students taking this qualification each year; currently the 6th most popular GCSE); and at A-level (ca 30,000/yr) (one of the top ten A-levels) have enhanced the coverage and demand for data skills generally, and geospatial skills, analysis and applications specifically. This geospatial content is part of the taught courses and also included within the assessment frameworks for GCSE and A-level.

Policy interventions, notably the inclusion of geography GCSE in the English-baccalaureate, has encouraged more students to study geography at GCSE in England. This is not the case in Wales, Scotland and Northern Ireland. **Opportunities to encourage broader uptake to GCSE (or equivalent) should be explored and encouraged with the respective school educational policy bodies.**

Many teachers lack experience and confidence in the delivery of the content of the new school-level curricular; they need more training, resources and support in delivering the richer geospatial

content in inspirational ways. **A national programme to deliver teacher-CPD, resources, networking and mentoring is needed for teachers of geography in schools.** The Society has been working with the Nuffield Foundation to deliver such a series of events and resources for teachers to support the teaching and learning of digital skills generally. That project work comes to an end this year.

Geography has a **shortage of specialist teachers**. DfE are funding ITT scholarships and training through the Society. With this too, there is scope to support more training in geospatial skills, more awareness of applications and opportunities, and thus enhance the learning and understanding of young people.

In addition, beyond geography, opportunities exist, but more support is needed, to champion **cross-school (cross-subject) initiatives to introduce core concepts of spatial data** through other subjects (e.g. mathematics, computer science, design, economics, business studies etc). The Society has supported engagement between geographers and other subject teachers to explore such partnerships, but these need to be scaled up and other subject associations and teacher-bodies need to be engaged.

Esri UK launched a programme in April 2017 to give ArcGIS Online free to all UK secondary schools, attempting to remove two barriers - installation and cost. They also launched the Geomentors programme, working with the Society to network geospatial professionals (those with expertise) with teachers, along with resources, to support the teaching and learning of GIS. These initiatives are also championed through events such as GIS day. These programmes have been well received and successful. To date there has been uptake of ArcGIS Online in >1700 secondary schools, benefiting >70,000 students. This is the order of a fifth of secondary schools across the UK. Clearly, and importantly, there are opportunities to do more: ca. 80% of secondary schools are not accessing these resources. The Society has worked with the four exam boards and with Esri UK to promote the opportunity. We recommend the **Commission work with DfE, and the Society and Esri UK, to join together through communications and influence to extend the reach, awareness and uptake of the free software, resources and Geomentors**.

Unlocking greater value (economic, social or environmental) of geospatial data will result from new applications, innovation and creativity (as well as greater awareness and skills). Initiatives are needed to develop this **innovative imagination and capacity** amongst young people at schools. One productive route would be to launch a competition for **geospatial-apps** (modelled loosely on the ideas of Geovation but for a school students). This could work with employers/industrial and media partners to raise the profile. This RGS-IBG would be delighted to partner on this, building on experience with initiatives such as Young Geographer of the Year.

In addition, there is a need to showcase the potential and excitement of geospatial applications to school level students whose interests will lead to careers not only in geography, but engineering, mathematics, data science, business, design etc. This requires investment in a broad suite of **imaginative careers profiles** that can be used by teachers, career advisors (working through national networks) and directly with students too. This should actively link with STEM, social science and humanities disciplines too, and drawing on school Ambassadors programme (both Geography and STEM). These should be pitched at students of all ages to fire their imagination, understand the possibilities, and recognise how expertise (or just knowledge) of geospatial data, technologies and applications can lead into successful careers, address key social, economic and environmental challenges, and benefit society.

Initiatives with schools, to showcase applications and careers, are key elements of what is also needed, **broader public relations activities to share success stories and raise the profile of geospatial** to the public focused on themes important to them. A festival, street-exhibitions, citizen-geography activities all could be elements of this. As one small example the Exhibition Road festival this summer (involving Science Museum, Imperial etc) will focus on space.

Higher education

Reports (such as Geobuiz, 2018) document that the UK stands out in terms of provision of geospatial training.

In preparing for this submission we updated our directory of geospatial programmes and courses in the UK, related to geography. Through this we identified 7 specialist undergraduate courses; 215 undergraduate modules; 90 Masters degree programmes; and 156 short courses. Geospatial education is increasingly being delivered in settings outside traditional realms of GIS, remote sensing and geomatics (in engineering, architecture and planning, business, public health). A fuller understanding of these courses, parts of courses, would be valuable within as well as across higher education institutions to encourage collaboration and interdisciplinary teaching. An **accessible and comprehensive directory** of formal provision is needed, across disciplines and institutions, to identify good practice, gaps in provision and foster new opportunities.

Based on discussions with leading university based educators, we heard expressions of interest in the development of MOOCs to bring basic geospatial understanding to new entrants, and new models for interdisciplinary teaching. **Forums need to be convened to bring interested parties together and catalyse development and delivery. Critically, employers/industry need to integral to these discussions from the outset to ensure the full suite of skills, knowledge and understanding is being delivered (**i.e. coding (e.g. in R, Python), visualisation (e.g. Tableau, Alteryx) and database management, as well as core-GIS skills).

Accessing new forms of data, especially via APIs, is also a key competence that needs to be developed, as well as an appreciation of the underlying systems that generate such data. Furthermore, particularly with new opportunities (e.g. administrative data, crowd-sourced data, human-sensor etc) and heightened awareness and concerns about personal data, confidentiality and ethics, education around professional values is important for geospatial professionals. Geoprivacy and ethical spatial data handling are key issues.

GISRUK (an annual academic-led conference that draws together researchers from a broad range of disciplines, including but not limited to, Geography, Environmental Science, Ecology, Computer Science, Planning, Archaeology, Geology, Geomatics and Engineering) **provides one obvious forum for an annual meeting/discussion to foreground skills training provision and skills needs** and to engage university educators.

In our interviews higher education staff, as with teachers in schools, expressed concern about **having sufficient time and resource to stay abreast of state-of-the-art technical skills** required in the rapidly evolving geospatial technical landscape. This needs to be highlighted as a priority and resources (time, funds, and opportunities) need to be made available for this. Short industrial or public sector placements/secondments could help in this realm.

Provision of geographical/geospatial training in further education and through technician level training is limited. A small number of **geospatial mapping and science apprenticeships** (level 3 and level 6) have been developed, and other standards make reference to geospatial training. The former have been developed by RICS to serve the needs of the surveying/geomatics profession. We are keen to see geographers engage with these more and to explore the extent to which they can provide **pathways for other elements of geospatial training at entry and advanced level**, or if new qualifications need to be developed. We know of a small number of geography departments interested in **higher-level, geospatial apprenticeships, focused more on data analytics**. These conversations need to be taken forward; key stakeholders drawn together; and barriers for uptake in universities, or further education institutions, identified and addressed.

Research and innovation

In the higher education research and innovation space, there are a number of pockets of geospatial expertise and excellence – established and emerging. Programmes exist, through UKRI awards, (e.g. Future Leaders) to recognise and raise the profile of expertise and innovation more widely and to foster collaborations with industry. **A directory of expertise, proactive**

nominations for recognition (with associated media profile) would serve to raise awareness of this excellence.

More geospatial awareness and training needs to be embedded in **interdisciplinary PhD training**. The UKRI doctoral training centres serve as one vehicle through which to do this. Mapping of existing provision of training across ESPRC (in particular), NERC, and ESRC doctoral training centres would be a helpful first step, as would involving more industry partners and advisors in evaluating the current offer. **Focused calls, or cross-centre training programmes**, could then follow.

Employers' needs

Numerous reports have been published based on skills needs and gaps based on employment data, surveys and interviews. Some of these are summarised and collated in our companion briefing document.

Common themes relate to the lack of digital/data skills generally; to the lack of knowledge of geospatial concepts (and implications for geospatial data) amongst computer scientists, software engineers and data analysts; and to the lack of data science skills (coding, visualisation, database management etc – noted above) amongst those trained through 'traditional' geospatial routes (geodesy and surveying, cartography, GISc etc).

A stronger evidence base of needs and gaps is critical to ensuring programmes are in place such that the right skills are anticipated, cultivated and delivered for entrants at all levels in employment. Here we draw specific attention to the exciting opportunities offered by the innovative methodology developed by Nesta, which involves (near) real-time analysis of job advertisements (ca 41 million to look at skills and skills clusters and employment sectors (see the accompanying document for more details). Such results could be overlain on local authorities/journeys to work to gain insights into the regional pattern of demand and/or to draw on information in other R&D platforms (glassAI, GITHUB, academic papers etc). We would welcome the opportunity to work with the Commission and Nesta to use this approached, modified slightly, to gain new insights into existing and emerging skills needs and gaps. Key to this will be the development and use of a shared (dynamic) taxonomy of skills.

Accreditation and professional standards for practioners

These are critical in recognising and signalling different levels of competence and expertise. Producing and consuming geospatial data intelligently, and interpreting it to unlock economic value and deliver social benefits to our citizens, **does require specialised skills**. These need to be clearly articulated and captured in a **framework of professional competencies**.

Chartered Geographer (GI) (CGeog GI) provides one standard to independently recognise an advanced level of professional expertise and competence. The accreditation has been adopted across the public and private sectors, but more needs to be done to encourage its alignment and uptake (e.g. with industry bodies such as the Chartered Insurance Institute and Association for British Insurers).

Chartered Geographer is underpinned by a **competency framework and professional code of practice.** There is scope to develop this further and the Society would welcome working with the geospatial community to do that. Currently, we are collaborating the Head and Deputy Heads of the Geography Profession within GSE in government to ensure alignment of standards and expectations across departments/agencies and with Chartered Geographer. Discussions are also underway about an earlier (entry-level) professional recognition, for those in the first few years in the profession, that codifies a commitment to professional development and mentoring. This will be developed to be appropriate for those beyond the public sector to ensure transferability between sectors and workplaces.

There are very special opportunities afforded within government, and beyond, through the work of the **new profession of geographers in GSE**. The head of the profession, [Text redacted] and a number of the deputy heads charged with professional standards specifically, will be key to the

development of geospatial training, standards, and accreditation of expertise for those involved in geospatial within government. They are particularly well placed to identify synergies and capitalise on opportunities with allied professions (e.g. the digital, data and technology profession) and in embedding good geospatial practice in the frameworks and competencies of other professions (economics, social research, statistics as examples).

Q3. What are the geospatial skills needs and gaps in your organisations, how can these be most effectively addressed, and how can careers in the sector be best promoted?

Please see responses above in Q2.

Q4. Are there any publicly or privately-held geospatial datasets that are currently challenging to access or use or of insufficient quality, but which you or your organisation would find valuable if these issues could be resolved? Please explain why this would be of value, and how access/quality could be improved?

Q5: Do you anticipate that any changes will be needed to the both address data and the wider address ecosystem, to support emerging technologies? Please provide evidence of value to support any proposed changes.

Q6: How should the commission be looking to develop the UK's capability in Earth observation data, both technologically and to support an effective market?

Q7. Which new technologies should the commission focus on to provide new opportunities to process and exploit geospatial data for economic growth?

Q8. How can geospatial data and applications be used to support enhanced roll-out of future technologies?

Q9: What are the options for how public sector organisations could continue to invest in maintaining and enhancing our geospatial data assets?

Q10: What areas of the underpinning geospatial infrastructure such as positioning technologies, including GPS and indoor positioning systems, and geodetic networks and frameworks to support them, should we be prioritising the development of, in order to support the emerging requirements for geospatial data?

Q11: What role should the private sector have in both the development and maintenance of the underpinning infrastructure and enhancing the UK's geospatial data assets?

Q12. Do you face challenges when working with geospatial data from across the public sector? If so, what are they and how could value be better released? Are there any technical remedies or standards that could be adopted to improve the interoperability of geospatial data? Please provide supporting evidence of what these remedies could help to accomplish.

Q13. How can the Geospatial Commission act as a more effective customer for geospatial data on behalf of the public sector?

Q14. Are there any additional geospatial datasets, from the other partner bodies or other sources, that the public sector would derive significant benefit from having access to, that might have novel and valuable use cases? What would that access look like?

Q15: How can we best develop a single UK strategy, ensuring alignment between the individual strategies across the UK while still allwoing for regional variations?

Q16: How can we best ensure effective local authority coordination and sharing of best practise, using location data to better deliver public services?

Q17: As a result of this analysis, we are prioritising the exploration of possible initiatives in the high-value categories identified:

- **property and land**
- **infrastructure and construction**
- **mobility**
- **natural resources**
- **sales and marketing**

What are the existing or potential geospatial applications which could be scaled-up or developed in order to capture economic value? (We would

particularly welcome responses from industry and other bodies engaged in these sectors.)

Q18: Are there any other areas that we should look at as a priority?

Q19: What are the main potential private and public sector innovations that will rely on the use of geospatial data to rollout, and are there corresponding regulatory challenges?

Q20: How best can we make the UK's presence in the international geospatial world more visible?

Q21: Where should the UK be looking for points of comparison overseas? Who are the other international exemplars? What best practice is being modelled overseas that we can learn from?

There is much good practice overseas. We encourage the commission to also involve international experts (e.g. from Singapore, USA, Netherlands etc) in its advisory and evaluative bodies.

Thank you for your time in completing your response to our call for evidence.

Any questions, please get in touch with the Geospatial Commission via geospatialcommission@cabinetoffice.gov.uk

Geospatial Commission: Call For Evidence Response Questionnaire

Please submit your completed questionnaire to:

geospatialcommission@cabinetoffice.gov.uk.

Clearly title your email *'Call for evidence response'*.

About you and your organisation

Name	[Text redacted]
Organisation	Royal Institution of Chartered Surveyors (RICS)
Job title	[Text redacted]
Address	[Text redacted]
E-mail	[Text redacted]
Telephone	[Text redacted]

Please select which of the following best describes you as a respondent:

Respondent	**Please mark with a X**
Academic	
Business representative / trade body	
Central government	
Charity or social enterprise	
Individual	
Legal representative	
Local government	
Large business (over 250 staff)	
Medium business (50 to 250)	
Small business (10 to 49)	
Micro business (up to 9)	

Other - please state	**Professional Institution**

Call for evidence - three key themes

We have identified three high-level themes that could help our approach to setting a strategy which are as follows:

1. **Supporting innovation in the geospatial sector**, exploring how to secure cutting edge skills, the right access to data, and opportunities from emerging technologies for the geospatial sector itself
2. **Enhancing the UK's geospatial assets,** looking at how best to align interests, avoid duplication, and instill best practice across the whole public sector
3. **Driving investment and productivity in geospatial applications**, asking in which wider sectors the most value lies from better exploitation and use of geospatial data, in the UK and internationally

Our questions

Q1. Is our view of the geospatial data types accurate? If not, what should be included or excluded from this?

The listing seems a little old fashioned and overly orientated on small/medium scale 'GIS' applications. The national geospatial strategy is a great opportunity for the UK geospatial industries to move on from the traditionalist 'GI' mentality of previous years (UK Location Strategy) and fully embrace all aspects of geospatial innovation, this can be engineering, land & property, planning and/or geography orientated. RICS would emphasise the importance of large scale data capture, the UK geodetic network (and its densification) and maintenance and the need to think on the integration of GIS (wide area) and BIM (small area) datasets. The evolving concept of 'digital twins' (a seamlessness between the existing and digital environments) will require a new approach when thinking of geospatial information and its capture, accuracy and applicability. We will be repeating the emphasis on the lack of a consistent national approach to 'planning & development' geospatial data issue during our response but suffice to say that the lack of a coherent plan has serious ramifications across a range of sectors from cross border infrastructure to provision of affordable housing in the areas that need it to green belt management and urbanisation. Just like the partner bodies listing, RICS would suggest that the geospatial commissions view the listing below as constituting a geospatial industries professions partnership:
AGI, RICS, TSA, CICES, RIBA, RTPI, ICE

The Geospatial Commission should support the concept of applications that lead customers (citizens and professionals) through a business process and provide them with answers rather than expecting them to perform the analyses themselves

using geospatial information.

A great example is the assessment of solar energy potential application (http://www.uvek-gis.admin.ch/BFE/sonnendach/?lang=en) developed jointly by the Swiss Federal Energy Office, MeteoSwiss and swisstopo (National Mapping Agency). The user is unaware that the application makes extensive use of geospatial information. It is the answer that the user is interested in.

Q2. In addition to current government policy, what are the areas of geospatial skills where the commission could best focus, to help ensure the necessary capability within the UK for the future?

RICS is very supportive of the current advanced apprenticeship initiatives (geospatial surveying level 3 & 6). There is a real need for 'hands on' data capture, surveying and engineering surveying skills. Geospatial, unlike GIS, is also about high accuracy, precision engineering applications – there is a need to embed geospatial understanding and techniques into other related professions such as civil engineering, planning, infrastructure, architecture, geography, property and land management. The commission should explore MOOC technology (as used by USAID and recently Tech University Munich) to bring basic geospatial understanding to new entrants and other professionals.

Q3. What are the geospatial skills needs and gaps in your organisations, how can these be most effectively addressed, and how can careers in the sector be best promoted?

We are witnessing more large (international and national) property and multi-disciplinary practices incorporating geospatial knowledge and technologies within their organisational structures and we are also witnessing a skills shortage across the geospatial surveying sectors. Careers should be targeted at school leavers and in conjunction with existing initiatives (Class of your own, geomatics.org, #lovesurveying etc). Graduates from cognate courses especially geography should be targeted.
RICS has developed a broad pathway to professional membership called the Land & Resources APC & AssocRICS pathway, this is proving popular with a wide variety of stakeholders (utilities, Gov agencies, multinational practices) who may have felt other RICS pathways were over specialised and restrictive. We have made sure geospatial surveying and knowledge is one of several core elements to this new pathway.

Q4. Are there any publicly or privately-held geospatial datasets that are currently challenging to access or use or of insufficient quality, but which you or your organisation would find valuable if these issues could be resolved? Please explain why this would be of value, and how access/quality could be improved?

HMLR hold a substantial portfolio of commercial property leasehold information (all 7 years + leasehold data can be tagged as confidential) – we are aware of the legislative changes needed to release this data but are of the view that this might be something for the commission to lobby HM Gov on. As already mentioned, the UK is bereft of any kind of coherent national planning geospatial framework.

Q5: Do you anticipate that any changes will be needed to the both address data and the wider address ecosystem, to support emerging technologies? Please provide evidence of value to support any proposed changes.

NA

Q6: How should the commission be looking to develop the UK's capability in Earth observation data, both technologically and to support an effective market?

The Commission should add the 'catapult' initiatives to its core stakeholder listing, the satellite technology catapult (based at Didcot) is especially relevant in this regard (as are several others especially Intelligent Cities) and are increasingly working globally. They are also exploring their potential in the land & property sectors (with offshoot start-ups such Orbital Witness) and with UN FAO/Habitat on tech enabled land administration in the developing world. The EU Copernicus initiative (and EO sentinel data availability) has been a 'game changer' for the integrated use of EO by numerous industries, the commission should integrate with and follow their lead.

Q7. Which new technologies should the commission focus on to provide new opportunities to process and exploit geospatial data for economic growth?

The Commission should carry out a simple audit of current and coming technologies (AI/ML, Blockchain, BIM, digital twins, UAVs) and who is already involved (BuildingSmart, OGC, catapult(s)). The technology element is a moving target but AI/ML & blockchain tech do seem very relevant to geospatial applications. Advances in GNSS technology and the advent of new systems (Galileo etc) should also be tracked, as should geospatial survey technology (machine control tech).

Q8. How can geospatial data and applications be used to support enhanced roll-out of future technologies?

The interconnection between GIS & BIM is especially exciting and bringing different scales, policy frameworks and ownership issues to the fore. The Commission should make sure to be linked into supporting infrastructure such as 5G telecoms rollout, smart city initiatives & distributed energy network development. Geospatial information can bring a lot of enhancement to other future technologies (public transport tech, driverless cars, high tech agriculture). Geotech can also bring benefit to more mundane sectors such as enhanced property taxation, land use and registration systems. Denmark has recently moved to a fully automated geo enabled property valuation and taxation system https://digst.dk/media/16165/ds_singlepage_uk_web.pdf

Q9: What are the options for how public sector organisations could continue to invest in maintaining and enhancing our geospatial data assets?

RICS would underline the need for public sector organisations to understand the providence of geospatial information and how it is underpinned by large scale survey data capture, ongoing revision and maintenance and the primacy of the Geodetic network as framework for all applications from large scale civil engineering to Rural Payments Agency RPA activities. Maintenance and currency are key issues for the geospatial strategy and the commission should give these issues a lot of attention. Geospatial data capture cannot always be achieved by high tech solutions (UAVs, EO etc), certainly not to the accuracy needed by many industries. RICS has produced a now global standard on Survey Detail Accuracy which outlines scales, accuracies and methodologies – the geospatial commission should look to adopt industry standards and practice and look way beyond GI software approaches and world views.

Q10: What areas of the underpinning geospatial infrastructure such as positioning technologies, including GPS and indoor positioning systems, and geodetic networks and frameworks to support them, should we be prioritising the development of, in order to support the emerging requirements for geospatial data?

Positioning technology, the underlying UK geodetic network (OSNet) and the maintenance and updating of the UK Geoid (OSGM14) are very important aspects of the remit of the commission. Geoid updates and related transformation parameters (OSTN14 current) are expensive and require rare UK expertise, but they create the geodetic basis for the establishment and mass usage of OSNet and a very accurate GNSS capability. Priority must be given to maintaining the geodetic network and related activities, this will become even more important as critical activities (security, transport, health, energy etc) become more reliant on accurate geospatial information. Future requirements will be more accurate rather than less.

Q11: What role should the private sector have in both the development and maintenance of the underpinning infrastructure and enhancing the UK's geospatial data assets?

The private sector has a role to play when ‘densification’ of a network is required, however ultimate responsibility and therefore liability remains with state agencies. The geodetic network (and related activities) are of national significance, private firms can engage in the provision of GNSS enhanced data services (real time RTK) as is currently available.

Q12. Do you face challenges when working with geospatial data from across the public sector? If so, what are they and how could value be better released? Are there any technical remedies or standards that could be adopted to improve the interoperability of geospatial data? Please provide supporting evidence of what these remedies could help to accomplish.

The connection of the geospatial industries with ‘standards’ and standards process are quite good, from ISO TC211 and OGC working groups to online communities such as Building Smart and the ongoing challenges of inspire – the geo industries are quite a way ahead in our understanding of standards issues. Addressing seems to be solved, as opposed to the chaos of previous years. Interoperability of software rather than datasets is a major issue. The success of the Digital twin concept and the linking of BIM (individual buildings) with wide scale GIS and Smart City (CityGML) will hinge on software interoperability issues (and related data connectivity). The Digital Street concept as championed by HMLR is a good example of how streamlined, customer focussed data provision can add the efficiency of the land & property market.

Q13. How can the Geospatial Commission act as a more effective customer for geospatial data on behalf of the public sector?

N/A

Q14. Are there any additional geospatial datasets, from the other partner bodies or other sources, that the public sector would derive significant benefit

from having access to, that might have novel and valuable use cases? What would that access look like?

Rural payments agency (RPA) – we believe that access to the Rural Payments Agency database would have multiple benefits for UK land administration, land use planning (as other nations) and potentially taxation. This RPA dataset can act almost as 'ghost register' and is disconnected from HMLR datasets, although it does show the true and current use of UK land.

Commercial property lease information: HMLR may have issues with the legality of releasing this dataset due to legislation.

Environment agency – lidar flood mapping geospatial datasets (EA Geomatics is an offshoot section which specialises in coastal/inshore and inland land/water surveys).

Planning information: the national planning inspectorate https://www.gov.uk/government/organisations/planning-inspectorate really needs to take a more active role in the provision of national planning data provision and localised geospatially enabled spatial plans. The UK is a mess where coherent planning and development data availability is concerned, although this data is very valuable to the P&D and investment sectors.
Resilience and emergency planning: we have highlighted the importance of the UN Sustainable Development Goals (SDGs) within our response and RICS would underline the importance of a Spatial Data Infrastructure (SDI) that is fit for purpose as attempt to manage the effects of climate change and improve the resilience of our national built and natural environments. Flooding will increase in frequency and intensity in the UK for example https://interactive.carbonbrief.org/impacts-climate-change-one-point-five-degrees-two-degrees/#
Emergency planning (environmental, terrorism, sporting events, fire) is also a sector that requires a coherent geospatial strategy.

Utilities: There have been several geo related projects in this sector (project Iceberg Ordnance Survey GB) and the National Joint Utilities Group NJUG but again this is sector that requires accessible geospatially enable information. Underground utility data is very difficult to aggregate and access (due to a variety of reasons, privatisation has not helped in this regard).

3rd party input of geospatial information – private sector survey firms (www.tsa-uk.org.uk) capture a vast amount of high quality/large scale geospatial information every day and could be utilised to enhance the national dataset. This would need 'vetting' and careful management but in for example the provision of post housing development 'as built' geospatial surveys this could save a lot of conflict issues that tend to follow on in the future.

Q15: How can we best ensure effective local authority coordination and sharing of best practise, using location data to better deliver public services?

This strategic aspect might be better divided into policy considerations (high level principle on the use of geospatial information (economic, social, political, environmental) and a more technical use-based series of internal training (or MOOC massive online course) for those at the front line of geospatial usage (waste services, health provision, schools etc)

Q16: As a result of this analysis, we are prioritising the exploration of possible initiatives in the high-value categories identified:

- **property and land**
- **infrastructure and construction**
- **mobility**
- **natural resources**
- **sales and marketing**

What are the existing or potential geospatial applications which could be scaled-up or developed in order to capture economic value? (We would particularly welcome responses from industry and other bodies engaged in these sectors.)

Property and land

We at RICS would see our core area of interest as the land & property sectors, we not only encompass professional chartered members in the geospatial sector but also valuation, development, residential and commercial property, building and quantity surveying and facilities management. The land & property markets are central to the economic well-being of UK PLC and geospatial information, and its availability (with relevant & added value) is a central element of ensuring future integration of technology and use. The UK benefits from one of the most effective land & property taxation systems in the world (certainly in terms of % of GDP – OECD) and the increased integration of mapping, legal registration/ownership, valuation and taxation information would help to encourage use. Automated valuation models (AVM) when combined with the England/Wales council tax regime could update a very out of date system. Denmark has already gone down this road. We would fully encourage the further integration of OS, HMLR and VOA into a more solidified union. Geospatial data also underpins the Compulsory Acquisition regime in England/Wales, this is a fraught and complex sector which is dependent (due diligence) on access to a lot of localised and wide scale geo datasets (amongst much more), geospatial data availability when aggregated with

numerous other related land & property datasets can ease the 'transfer and compensation process' and enable international land transfer standards such as ILMS https://consultations.intstandards.org/consult.ti/ilms/consultationHome to be used.

We have already mentioned the dire need for consistency in the provision of planning and development geospatial information. RICS has been very impressed by the work of the satellite applications catapult and its test project with Milton Keynes LA on using high resolution imagery to auto-update spatial planning (change detection) – a powerful tool which has global implications and use.

We have also mentioned the RPA and the opening of rural payments information and land use data (land valuation and pricing information is very difficult to aggregate, unlike the mass of information available on residential property indexes).

We would also highlight the increasing prevalence of neighbour disputes (particluarily those involving boundary issues – RICS receives over 5000 compliants PA and the county court system is struggling to deal with this sector). Good geospatial information can solve many un necessary conflicts and the combination of current geospatial information with existing land registry title needs to be explored. Land registry and OS are at the core oft his issue but so to are 'bad' development plans and the lack of understanding (and ability) to accept 'fixed'/'determined' boundaries into land registry systems (with ease). The processes and legal issues are solved, LR guides are available but the opening up of this abilty to permanent solve disputes would be good for UK PLC. The strong GNSS RTK network makes absolute location 'repeatability' to within acceptable industry standards (RICS Measured surveys 3rd ed 2014) achievable.

Infrastructure and construction

We have previously underlined the critical importance of OSNet and the UK geodetic network to infrastructure provision (we mentioned the densification of the OSNet network on HS2 and the machine control this enables), we would also highlight that geospatial data is spoken of mainly in connection with CAPEX construction expenditure (the actual physical Contruction) and whilst this is critical geospatial data also has a major role to play in the long term strategic asset management that national and local infrastructure requires. OPEX expenditure (asset maintenance, upgrading, facilities management etc) usually greatly outstrips CAPEX and the long-term integration of a strong geospatial strategy will be key to the use of BIM, digital twin, smart cities & the management of the 'digital' built environment. A bit of a change of mind set.

We would also suggest that the concept on 'infrastructure' is broadened to include telecommunications and broadband connectivity and future technology roll out (5G). geospatial data has a major role to play (5g technology is line of sight

orientated and accurate city models such as those developed by the Manchester test bed Cityverve) will become even more important.

Another aspect of infrastructure development that would benefit from a more coherent approach to geospatial and land information is land referencing. Land referencing is used to create the necessary documentation to support a development consent order (DCO), compulsory purchase order (CPO), transport and works act order (TWAO), vesting order (VO) or hybrid bill. This a key element of infrastructure provision and is also a major part of any project cost (witness the excalating costs of HS2 due to a mis calculation of the land acquisition and CPO process. Geospatial information is a key part of these process and help tie all of the disparate land elements together.

Natural resources

We believe you could extend this topic to include renewables and the national grid. Localised power distribution and provision (and perhaps blockchain supply chain tech) is becoming increasingly important, geospatial tech has the power to unlock the connection between location and access to solar, planning, grant regimes, allowable development data and much more. Offshore development (The Geospatial Commission should develop links with Crown Estate) of wind and wave energy is reliant on the integration of land, coastal and offshore data sets, as is the management of coastal and offshore natural assets and the protection of the numerous (and recent) marine eco zones as designated by the Marine Management Organisation MMO.

Q17: Are there any other areas that we should look at as a priority?

It would be worthwhile looking into the land & property transfer 'due diligence process and existing standardised data transfer protocols such as ILMS (International Land Measurement Standards), RICS and Law Society protocols. The Coal Authority has recently opened its datasets (CON29M Law Society protocol) to firms, this is a great example of public sector data having significant 'added value' enabled by expert professions and private sector involvement (Terrafirma in this case). Other sectors such as Compulsory Purchase & acquisition would benefit from better engagement and we iterate our thoughts that the Planning Inspectorate be added to the core grouping.

Q18: What are the main potential private and public sector innovations that will rely on the use of geospatial data to rollout, and are there corresponding regulatory challenges?

Governance and regulation always tends to lag behind technological advances, the sectors we see as causing potential clashes are the implementation of (amongst many others); Smart City technology and its connectivity with BIM (BSI have done some good work in this space on policy considerations), the upgrading of the UK (regional) land & property taxation systems to incorporate geospatial, census, land registration and market value (perhaps based on Automated Valuation Models and the use of AI/ML) – this would tie geospatial directly to revenue raising strategies and really needs to be considered, and natural capital and ecosystem value. UK agricultural policy is moving towards a more 'environmental' stewardship model (post Brexit) and will require a much more integrated geospatial approach to Rural Payments Agency, environmental planning and evolution of natural capital policy requirements and thought.
We are sure that others will go into more in-depth narratives on autonomous cars and future mobility. This new technology will require an astonishing amount of geospatial data to operate effectively from high accuracy GNSS and inertial positioning to high precision engineering and 3d environment data. RICS would also raise the issue of advanced public transit systems (trams, underground/overground, mono-rail, auto bus etc) and their need for geospatial information which can be used for all stages of development including post construction land value capture (valuation, taxation and geospatial working in tandem). Increasing use of cycling will be further encouraged by authorities and will also benefit for advanced geospatial information.

We would urge the geospatial commission to adopt holistic vision when thinking on the future use and application of geospatial information. The UN Sustainable Development Goals SDGs should be highlighted as a priority by the commission and where and at what level geospatial data can help UK PLC achieve its obligations.

Q19: How best can we make the UK's presence in the international geospatial world more visible?

The UK is very visible on the global geospatial stage through our involvement with organisations and agencies such as UN GGIM (UK to host in 2020) (and other UN Agencies such as UNFAO & UN Habitat), OGC, FIG, CLGE, IAG, ISPRSC and World Bank. There are numerous key conferences and events during each year. The UK geospatial industries have come together under the auspices of GeoBusiness 2019 (May 2019), which acts as an annual lodestar for numerous professional organisations. We would also suggest that the Commission adopt the global language and use of the UN Sustainable Development Goals (SDGs) and as a priority seek to envisage how and where geospatial information and expertise enables each of the 17 SDGs (and the specific tiers SDG 1.4.2 land tenure – for example). The UK has an active SDG implementation group focussed on enabling private sector organisations to incorporate the SDGs into their corporate social responsibility CSR plans https://www.unglobalcompact.org/library/5628 http://www.unglobalcompact.org.uk/ - geospatial information should tied to this

initiative as an enabling force for good.
Capacity development is a major issue facing the land & property sectors worldwide, we would suggest that the commission work with DfID colleagues (LEGEND programme) on a MOOC outlining geospatial capacity development (USAID https://www.canvas.net/browse/usaid/courses/usaid-land-tenure-2 did this and attracted over 15 000 participants).

Q20: Where should the UK be looking for points of comparison overseas? Who are the other international exemplars? What best practice is being modelled overseas that we can learn from?

When we look to our fellow professional geospatial surveyors globally – the main issue, almost existential in many regions, is geospatial technical and professional capacity development. There are just not enough geospatial surveyors.

In other sectors - Denmark has a new land & property taxation model (but is a very data rich environment) based on a very strong geospatial technology capability (imagery, GIS, valuation/AVM) which has revolutionised its revenue generation capability.

Sweden has adopted blockchain technologies for land & property transfer and numerous OECD nations are moving towards similar adoption.

Ireland (republic) is combining numerous government services into a single department (Taillte Eireann) bringing national mapping (OSI), land registration, valuation/taxation and planning together.

However, global benchmarking in our sectors is always difficult, the global geospatial outlook survey is a good snapshot but does have a commercial imperative, World Bank Doing Better Business 'registration of property' has a strong geospatial element(s), various nations have implemented or are thinking of Spatial Data Infrastructures (SDIs) with varying success and international initiatives such as InSpire and EuroGeographics (EU), FIG and UN GGIM (global) continue. It depends on what we view as important criteria for benchmarking? Revenue generation (property/land taxation UK 2nd after USA), Doing Better Business (UK 42nd, 1 place below Mongolia) due to legacy of historic land registration issues.

We would advise that the commission looks at numerous direct and connected benchmarking protocols and initially research just where the UK sits and can develop further.

Royal Mail response to the Geospatial Commission Call for Evidence

About Royal Mail

As the UK's sole designated Universal Service Provider for post, Royal Mail is proud to deliver a 'one price goes anywhere' service on a range of letters and parcels to over 30 million addresses (including 1.3 million businesses) across the UK, six-days-a-week.

Postcodes are a strong foundation for UK geospatial data

The Postcode Address File (PAF) is rightly recognised in the consultation as an important piece of the UK's geospatial infrastructure. We welcome the Commission's interest in exploring how to work together on PAF and we are keen to ensure the UK remains at the forefront of how we use geospatial data on an ongoing basis.

Next year is the 60th anniversary of the postcode. Royal Mail invested heavily in getting the public to use their postcodes to support efficient mail delivery. Postcodes are one of the most readily memorable pieces of information that a citizen has about their address and location. The addressing and postcode infrastructure was originally developed to help Royal Mail route and deliver mail. Today this postal address data is still essential to ensure efficient sortation and routing of parcels and letters for Royal Mail, as well as for the whole of the UK's delivery sector.

Postcodes are a core part of the national geospatial infrastructure, and have become easy to use indicators for areas and locations. They are the first choice for businesses, the public sector and citizens when it comes to searching for places in maps and satellite navigation systems. They are also commonly used by organisations to help calculate insurance premiums, define catchment areas and often feature in reports on national trends and changes. While the postcode was not originally designed for these purposes its ubiquity and simplicity means that it is not going to be easily or quickly replaced by alternative reference indicators.

PAF is a key enabler for many businesses

Since the 1990s PAF has been available to other, non-delivery businesses, and those businesses have incorporated it into the software that drives the customer management, procurement and e-commerce systems of tens of thousands of UK based businesses. The simplicity of the question "can I take your name and postcode please?" followed by a rapid address lookup against the file of the 30m+ UK delivery points, makes for highly efficient interaction between businesses and customers, public sector and citizens.

PAF is maintained to a high level of quality and accuracy by Royal Mail. This in turn enables us to make a reasonable return on PAF provided we maintain value for money. Searches against the file are available from as little as 1.3 pence each. It is important that we can continue to manage PAF on this basis to ensure we can maintain quality and accuracy.

We make over 5,000 changes to our PAF data every day. These changes are made available to customers daily, ensuring changes can be used by our customers as soon as possible. UK postal address info is widely recognised as the best and most accurate in the world and PAF is chosen and trusted by those who rely on address information to help in the identification and verification

of both people and places. This trust has been established by providing accurate and consistent data for use by customers over decades.

PAF is a key asset for Royal Mail

Royal Mail uses the PAF database daily to route mail efficiently and accurately to every single UK address. Royal Mail has made, and continues to make, substantial investments in building, developing and maintaining the PAF database. We commercialise this through licensing activities which helps underpin our ability to deliver the 'one price goes anywhere' Universal Service to 30 million addresses.

As the consultation paper rightly notes, "The potential economic and social rewards are large if we act to take advantage of this increasing opportunity." I hope that this includes collaborating to build on the existing assets that have placed the UK in a leading position on geospatial data, in particular the postcode and the Postcode Address File.

We would be happy to discuss the role of the postcode further if helpful to the Commission. [Text redacted]

RTPI response to HM Government National Geospatial Strategy: call for evidence

October 2018

About the RTPI

The RTPI champions the power of planning in creating prosperous places and vibrant communities. As learned society, we use our expertise and research to bring evidence and thought leadership to shape planning policies and thinking. As a professional body, we have over 25,000 members across all sectors, and are responsible for setting formal standards for planning practice and education.

General comments

We welcome the opportunity to respond to this consultation on the National Geospatial Strategy. We are excited at this increased attention to the potential of the UK's geospatial data infrastructure. If the Government follows through on this promise it could be of great benefit to planners and the planning system.

As a general point we want to emphasise the value of geospatial data to public sector decision-making. Whilst the economic potential of geospatial data is worthy of emphasis, the utility of data in informing decision-making, from local planning decisions up to national policy is important. This is true both for understanding needs related to particular areas, and for ensuring that policies link up together. Improving decision-makers access to quality, easy to use data, will improve decision-making at all spatial and governmental scales.

Our research 'A Map for England'[1] took English policies with a strong spatial dimension and mapped them to highlight overlaps. It showed that some policies and programmes, when considered against each other in relation to different parts of the country, may have unintended consequences. This clearly highlights the importance of publishing data in with consistent spatial identifiers. In the ideal, all policy should be clearly linked to the spatial area it will influence in order to make overlap obvious. The Geospatial Commission is in a great position to push for this.

[1] Wong et al. (2012), A Map for England, https://www.rtpi.org.uk/knowledge/policy/map-for-england/

Response to questions

Q3. What are the geospatial skills needs and gaps in your organisations, how can these be most effectively addressed, and how can careers in the sector be best promoted?

Data skills are already important to planners and will be increasingly crucial in coming years. We have identified this as a priority and are exploring how best to deliver training on this with members. We would welcome engagement from the commission on how best to spread digital skills in the planning profession.

We are currently working with Future Cities Catapult to look for opportunities to:

- Raise awareness of digital tools and approaches in planning, through signposting, guidance, conferences and outreach, possibly including a joint PlanTech conference in 2019 and a new PlanTech award as part of the RTPI annual planning awards
- Utilising the RTPIs extensive partnerships with academia, industry and professionals to research, analyse and communicate the key opportunities for PlanTech
- Embed PlanTech into academic and CPD courses to ensure that new and existing planners are well placed to lead on this agenda.
- Share the lessons and opportunities of PlanTech through the RTPIs wider international network

The RTPI is also developing apprenticeships for planners. We are interested in the Commission's ambitions to build geo-spatial skills into a wide variety of training and would welcome further discussion and support on this.

Different planners will need different digital skills. We expect some of the most common needs to be around:

- Digital tools such as BIM and GIS
- Social media and other digital community engagement tools
- Understanding of key concepts e.g. smart cities

Q4. Are there any publicly or privately-held geospatial datasets that are currently challenging to access or use or of insufficient quality, but which you or your organisation would find valuable if these issues could be resolved? Please explain why this would be of value, and how access/quality could be improved?

Land Registry ownership information is important for planning – therefore we strongly support moves towards completing the registries around the UK and making the data more accessible. It can help local authorities developing plans and assembling sites, for example to deliver new housing. It can also help citizens participate in planning processes. In particular, the National Polygon dataset should be prioritised, along with identifiers (e.g. Land Registry Title Numbers) that would improve linkage with other data.

The Geospatial Commission should also push for data to be collected and made accessible on beneficial owners of land, and options to purchase land. As it stands land options can be registered but do not need to declare that they are contingent on the allocation of land in a plan

or the grant of planning permission. They are not required to be registered or disclosed at all. The compulsory registration of such options would assist more effective plan making at all levels and the smoother and more transparent operation of the land market. It would also increase public confidence in the system.

The Geospatial Commission should make linking up data a major priority. As described above, our Map for England project attempted to bypass policy siloes by matching up datasets from different Government departments. This kind of linking of various types of data should be a standard working practice and the Geospatial Commission could help prepare a data infrastructure which makes this easy.

Q9: What are the options for how public sector organisations could continue to invest in maintaining and enhancing our geospatial data assets?

Our main public data infrastructure should be developed and maintained with public funds to pursue public interests, be they economic, environmental, or social, or to help improve policymaking. This data should then be made as open and accessible as possible.

There are a number of ways in which the land market could be made more effective with new data which could easily be mapped. The organisations involved in the Geospatial Commission should link up with others including the MoD, NHS, and ONS, to collect and publish data on a range of things, including[2]:

- **Comprehensive and transparent ownership data with key identifiers**. This would make it easier for local authorities to develop plans and assemble sites, and for citizens to engage with land use planning. Data on land ownership needs to be available in aggregate and over territories not simply to "purchasers". Understanding concentration of land ownership (and planning permissions) will help understand how to promote competition and diversity in development.
- **Beneficial owners of land, and options to purchase land**. As it stands land options can be registered but do not need to declare that they are contingent on the allocation of land in a plan or the grant of planning permission. They are not required to be registered or disclosed at all. The compulsory registration of such options would assist more effective plan making at all levels and the smoother and more transparent operation of the land market. It would also increase public confidence in the system.
- **Land prices by site and by hectare**
- **Mapped planning permissions with dates and details** of what the permission is for, who it was given to and the status of the development. This would mean that the spatial impact of housing delivery can be properly monitored. We explored this in our recent research, Location of Development[3], on why housing location is as important as supply. It would also mean that the distribution of permissions could be understood better.

[2] See also: KPMG and Shelter, Building the Homes we Need, p.60 https://home.kpmg.com/content/dam/kpmg/pdf/2015/03/building-the-homes-we-need.pdf#page=60

[3] www.rtpi.org.uk/locationofdevelopment

Q10: What areas of the underpinning geospatial infrastructure such as positioning technologies, including GPS and indoor positioning systems, and geodetic networks and frameworks to support them, should we be prioritising the development of, in order to support the emerging requirements for geospatial data?

The coverage of high speed broadband must be a priority as it will enable the collection and use of geospatial data.

Q11: What role should the private sector have in both the development and maintenance of the underpinning infrastructure and enhancing the UK's geospatial data assets?

As described above, our main public data infrastructure should be developed and maintained with public funds. However, the private sector certainly creates data which could contribute to the underpinning data infrastructure. More should be done to encourage private sector companies to share data relating to public spaces and services such as transport. This would be useful to planners seeking to improve urban design.

Q12. Do you face challenges when working with geospatial data from across the public sector? If so, what are they and how could value be better released? Are there any technical remedies or standards that could be adopted to improve the interoperability of geospatial data? Please provide supporting evidence of what these remedies could help to accomplish.

Licensing restrictions associated with the use of OS data is often cited by local authorities and other public authorities as a reason they can not release data they collect as open data.

In this and other cases, the Geospatial Commission should seek the minim um amount of restrictions on how datasets can be used and how derived data can be shared.

Q15: How can we best develop a single UK strategy, ensuring alignment between the individual strategies across the UK while still allowing for regional variations?

The Commission should collaborate with various different Government organisations, both to develop this strategy and on an ongoing basis. This might include, for example, the new MHCLG Digital Policy team.

Q16: How can we best ensure effective local authority coordination and sharing of best practise, using location data to better deliver public services?

Coordination between local authorities is essential to the digital transformation of planning, and in particular to making planning data more accessible.

We agree with the points made in Owen Boswarva's response[4], around:

- Making greater use of the Single Data List.[5] In particular we would like to see more consistent information collected by local planning authorities (e.g. on resourcing). Though this must be explored with an understanding of the cost of collecting data.

[4] https://www.owenboswarva.com/blog/post-gc2.htm
[5] https://www.gov.uk/government/publications/single-data-list

- Government mandating schemas for returns of geospatial and other data from council sources, to ensure consistency and interoperability.
- Replacing PSMA with open licensing of MasterMap data

In 2018 the ODI conducted research into the role open data plays in the delivery of public services. We agree with several of the recommendations from this report, including:

- the need to fund local authorities to experiment with ways of developing new uses for geospatial data
- the need to support collaboration between local authorities, including through supporting peer networks.

Q19: What are the main potential private and public sector innovations that will rely on the use of geospatial data to rollout, and are there corresponding regulatory challenges?

We are interested in how geospatial data will be involved in the development of autonomous vehicles. Increased use of AVs will require careful input from planners.

Q21: Where should the UK be looking for points of comparison overseas? Who are the other international exemplars? What best practice is being modelled overseas that we can learn from?

The US state of Montana provides an example of how information on land can be made accessible to everyone.[6] It is particularly interesting in displaying all land boundaries and land ownership, but also linking this with a wealth of other information (and adding more and more new linked datasets as time goes on).

One major advantage is that all the data is linked to properties. For any parcel of land you can easily find out information on a range of metrics including:

- the owner
- the property type
- the land value
- the land use
- the dwellings and other buildings

This highlights how valuable a move towards opening up Land Registry Title Numbers and the National Polygon dataset could be.

This kind of tool could help make planning, and in particular community participation in planning, more effective in the UK. Given the richness of UK geospatial data, this could easily be a world leading resource.

Geospatial Commission: Call For Evidence Response Questionnaire

Please submit your completed questionnaire to:

geospatialcommission@cabinetoffice.gov.uk.

Clearly title your email *'Call for evidence response'*.

About you and your organisation

Name	[Text redacted]
Organisation	Royal Town Planning Institute
Job title	[Text redacted]
Address	[Text redacted]
E-mail	[Text redacted]
Telephone	[Text redacted]

Please select which of the following best describes you as a respondent:

Respondent	**Please mark with a X**
Academic	
Business representative / trade body	**X**
Central government	
Charity or social enterprise	
Individual	
Legal representative	
Local government	
Large business (over 250 staff)	
Medium business (50 to 250)	
Small business (10 to 49)	
Micro business (up to 9)	

Other - please state	

Call for evidence - three key themes

We have identified three high-level themes that could help our approach to setting a strategy which are as follows:

1. **Supporting innovation in the geospatial sector**, exploring how to secure cutting edge skills, the right access to data, and opportunities from emerging technologies for the geospatial sector itself
2. **Enhancing the UK's geospatial assets,** looking at how best to align interests, avoid duplication, and instill best practice across the whole public sector
3. **Driving investment and productivity in geospatial applications**, asking in which wider sectors the most value lies from better exploitation and use of geospatial data, in the UK and internationally

Our questions

Q1. Is our view of the geospatial data types accurate? If not, what should be included or excluded from this?

No response.

Q2. In addition to current government policy, what are the areas of geospatial skills where the commission could best focus, to help ensure the necessary capability within the UK for the future?

.No response.

Q3. What are the geospatial skills needs and gaps in your organisations, how can these be most effectively addressed, and how can careers in the sector be best promoted?

Data skills are already important to planners and will be increasingly crucial in coming years. We have identified this as a priority and are exploring how best to deliver training on this with members. We would welcome engagement from the commission on how best to spread digital skills in the planning profession.

We are currently working with Future Cities Catapult to look for opportunities to:

- Raise awareness of digital tools and approaches in planning, through signposting, guidance, conferences and outreach, possibly including a joint PlanTech conference in 2019 and a new PlanTech award as part of the RTPI annual planning awards
- Utilising the RTPIs extensive partnerships with academia, industry and professionals to research, analyse and communicate the key opportunities for PlanTech
- Embed PlanTech into academic and CPD courses to ensure that new and existing planners are well placed to lead on this agenda.
- Share the lessons and opportunities of PlanTech through the RTPIs wider international network

The RTPI is also developing apprenticeships for planners. We are interested in the Commission's ambitions to build geo-spatial skills into a wide variety of training and would welcome further discussion and support on this.

Different planners will need different digital skills. We expect some of the most common needs to be around:

- Digital tools such as BIM and GIS
- Social media and other digital community engagement tools
- Understanding of key concepts e.g. smart cities

Q4. Are there any publicly or privately-held geospatial datasets that are currently challenging to access or use or of insufficient quality, but which you or your organisation would find valuable if these issues could be resolved?

Please explain why this would be of value, and how access/quality could be improved?

As a general point we want to emphasise the value of geospatial data to public sector decision-making. Whilst the economic potential of geospatial data is worthy of emphasis, the utility of data in informing decision-making, from local planning decisions up to national policy is important. This is true both for understanding needs related to particular areas, and for ensuring that policies link up together. Improving decision-makers access to quality, easy to use data, will improve decision-making at all spatial and governmental scales.

Our research 'A Map for England' took English policies with a strong spatial dimension and mapped them to highlight overlaps.[1] It showed that some policies and programmes, when considered against each other in relation to different parts of the country, may have unintended consequences. This clearly highlights the importance of publishing data in with consistent spatial identifiers. In the ideal, all policy should be clearly linked to the spatial area it will influence in order to make overlap obvious. The Geospatial Commission is in a great position to push for this.

Specific data:

Land Registry ownership information is important for planning – therefore we strongly support moves towards completing the registries around the UK and making the data more accessible. It can help local authorities developing plans and assembling sites, for example to deliver new housing. It can also help citizens participate in planning processes. In particular, the National Polygon dataset should be prioritised, along with identifiers (e.g. Land Registry Title Numbers) that would improve linkage with other data.

The Geospatial Commission should also push for data to be collected and made accessible on beneficial owners of land, and options to purchase land. As it stands land options can be registered but do not need to declare that they are contingent on the allocation of land in a plan or the grant of planning permission. They are not required to be registered or disclosed at all. The compulsory registration of such options would assist more effective plan making at all levels and the smoother and more transparent operation of the land market. It would also increase public confidence in the system.

Linking data:

The Geospatial Commission should make linking up data a major priority. As described above, our Map for England project attempted to bypass policy siloes by matching up datasets from different Government departments. This kind of linking of various types of data should be a standard working practice and the Geospatial Commission could help prepare a data infrastructure which makes this easy.

[1] Wong et al. (2012), A Map for England, https://www.rtpi.org.uk/knowledge/policy/map-for-england/

Q5: Do you anticipate that any changes will be needed to the both address data and the wider address ecosystem, to support emerging technologies? Please provide evidence of value to support any proposed changes.

No response

Q6: How should the commission be looking to develop the UK's capability in Earth observation data, both technologically and to support an effective market?

No response

Q7. Which new technologies should the commission focus on to provide new opportunities to process and exploit geospatial data for economic growth?

No response

Q8. How can geospatial data and applications be used to support enhanced roll-out of future technologies?

No response

Q9: What are the options for how public sector organisations could continue to invest in maintaining and enhancing our geospatial data assets?

Our main public data infrastructure should be developed and maintained with public funds to pursue public interests, be they economic, environmental, or social, or to help improve policymaking. This data should then be made as open and accessible as possible.

There are a number of ways in which the land market could be made more effective with new data which could easily be mapped. The organisations involved in the Geospatial Commission should link up with others including the MoD, NHS, and ONS, to collect and publish data on a range of things, including[2]:

- **Comprehensive and transparent ownership data with key identifiers**. This would make it easier for local authorities to develop plans and assemble sites, and for citizens to engage with land use planning. Data on land ownership needs to be available in aggregate and over territories not simply to "purchasers". Understanding concentration of land ownership (and planning permissions) will help understand how to promote competition and diversity in development.
- **Beneficial owners of land, and options to purchase land**. As it stands land options canbe registered but do not need to declare that they are contingent on the allocation of land in a plan or the grant of planning permission. They are not required to be registered or disclosed at all. The compulsory registration of such options would assist more effective plan making at all levels and the smoother and more transparent operation of the land market. It would also increase public confidence in the system.
- **Land prices by site and by hectare**
- **Mapped planning permissions with dates and details** of what the permission is for, who it was given to and the status of the development. This would mean that the spatial impact of housing delivery can be properly monitored. We explored this in our recent research, Location of

[2] See also: KPMG and Shelter, Building the Homes we Need, p.60 https://home.kpmg.com/content/dam/kpmg/pdf/2015/03/building-the-homes-we-need.pdf#page=60

Development, on why housing location is as important as supply.[3] It would also mean that the distribution of permissions could be understood better.

Q10: What areas of the underpinning geospatial infrastructure such as positioning technologies, including GPS and indoor positioning systems, and geodetic networks and frameworks to support them, should we be prioritising the development of, in order to support the emerging requirements for geospatial data?

The coverage of high speed broadband must be a priority as it will enable the collection and use of geospatial data.

Q11: What role should the private sector have in both the development and maintenance of the underpinning infrastructure and enhancing the UK's geospatial data assets?

As described above, our main public data infrastructure should be developed and maintained with public funds.

However, the private sector certainly creates data which could contribute to the underpinning data infrastructure. More should be done to encourage private sector companies to share data relating to public spaces and services such as transport. This would be useful to planners seeking to improve urban design.

[3] www.rtpi.org.uk/locationofdevelopment

Q12. Do you face challenges when working with geospatial data from across the public sector? If so, what are they and how could value be better released? Are there any technical remedies or standards that could be adopted to improve the interoperability of geospatial data? Please provide supporting evidence of what these remedies could help to accomplish.

Licensing restrictions associated with the use of OS data is often cited by local authorities and other public authorities as a reason they can not release data they collect as open data.

In this and other cases, the Geospatial Commission should seek the minim um amount of restrictions on how datasets can be used and how derived data can be shared.

Q13. How can the Geospatial Commission act as a more effective customer for geospatial data on behalf of the public sector?

No response

Q14. Are there any additional geospatial datasets, from the other partner bodies or other sources, that the public sector would derive significant benefit from having access to, that might have novel and valuable use cases? What would that access look like?

No response

Q15: How can we best develop a single UK strategy, ensuring alignment between the individual strategies across the UK while still allwoing for regional variations?

The Commission should collaborate with various different Government organisations, both to develop this strategy and on an ongoing basis. This might include, for example, the new MHCLG Digital Policy team.

Q16: How can we best ensure effective local authority coordination and sharing of best practise, using location data to better deliver public services?

Coordination between local authorities is essential to the digital transformation of planning, and in particular to making planning data more accessible.

We agree with the points made in Owen Boswarva's response[4], around:

- Making greater use of the Single Data List.[5] In particular we would like to see more consistent information collected by local planning authorities (e.g. on resourcing). Though this must be explored with an understanding of the cost of collecting data.
- Government mandating schemas for returns of geospatial and other data from council sources, to ensure consistency and interoperability.
- Replacing PSMA with open licensing of MasterMap data

In 2018 the ODI conducted research into the role open data plays in the delivery of public services. We agree with several of the recommendations from this report, including:

- the need to fund local authorities to experiment with ways of developing new uses for geospatial data
- the need to support collaboration between local authorities, including through supporting peer networks.

Q17: As a result of this analysis, we are prioritising the exploration of possible initiatives in the high-value categories identified:

- **property and land**
- **infrastructure and construction**
- **mobility**

[4] https://www.owenboswarva.com/blog/post-gc2.htm

[5] https://www.gov.uk/government/publications/single-data-list

- **natural resources**
- **sales and marketing**

What are the existing or potential geospatial applications which could be scaled-up or developed in order to capture economic value? (We would particularly welcome responses from industry and other bodies engaged in these sectors.)

We welcome the focuses on property and land. Geospatial data and technologies have the potential to make planning more effective and to free up time for planners to concentrate on pro-active planning.

Q18: Are there any other areas that we should look at as a priority?

No response.

Q19: What are the main potential private and public sector innovations that will rely on the use of geospatial data to rollout, and are there corresponding regulatory challenges?

We are interested in how geospatial data will be involved in the development of autonomous vehicles. Increased use of AVs will require careful input from planners.

Q20: How best can we make the UK's presence in the international geospatial world more visible?

No response

Q21: Where should the UK be looking for points of comparison overseas? Who are the other international exemplars? What best practice is being modelled overseas that we can learn from?

The US state of Montana provides an example of how information on land can be made accessible to everyone.[6] It is particularly interesting in displaying all land boundaries and land ownership, but also linking this with a wealth of other information (and adding more and more new linked datasets as time goes on). One major advantage is that all the data is linked to properties. For any parcel of land you can easily find out information on a range of metrics including: ● the owner ● the property type ● the land value ● the land use ● the dwellings and other buildings This highlights how valuable a move towards opening up Land Registry Title Numbers and the National Polygon dataset could be. This kind of tool could help make planning, and in particular community participation in planning, more effective in the UK. Given the richness of UK geospatial data, this could easily be a world leading resource.

Thank you for your time in completing your response to our call for evidence.

Any questions, please get in touch with the Geospatial Commission via geospatialcommission@cabinetoffice.gov.uk

Academic	
Business representative / trade body	
Central government	
Charity or social enterprise	
Individual	
Legal representative	
Local government	**X**
Large business (over 250 staff)	
Medium business (50 to 250)	
Small business (10 to 49)	
Micro business (up to 9)	

Other - please state	

Call for evidence - three key themes

We have identified three high-level themes that could help our approach to setting a strategy which are as follows:

1. **Supporting innovation in the geospatial sector**, exploring how to secure cutting edge skills, the right access to data, and opportunities from emerging technologies for the geospatial sector itself
2. **Enhancing the UK's geospatial assets,** looking at how best to align interests, avoid duplication, and instill best practice across the whole public sector
3. **Driving investment and productivity in geospatial applications**, asking in which wider sectors the most value lies from better exploitation and use of geospatial data, in the UK and internationally

Our questions

Q1. Is our view of the geospatial data types accurate? If not, what should be included or excluded from this?

I believe 'geospatial' and 'positional' are descriptively too similar as they both relate to location. Geospatial could also be described by its data format (i.e GeoJSON, GeoPackage) with 'positional' or 'geospatial linked' data in non spatial formats (i.e Excel, CSV) described as data that has a location element but isn't spatial in its raw form.

Q2. In addition to current government policy, what are the areas of geospatial skills where the commission could best focus, to help ensure the necessary capability within the UK for the future?

A focus on data sharing, management and web services / platforms is important to provide the best basis for all data owners to publish and centralise information, as well as accessing government / partner data most efficiently. data.gov.uk is a good start but could be improved (i.e encorporating map searching functionality to find data in specific areas).

Q3. What are the geospatial skills needs and gaps in your organisations, how can these be most effectively addressed, and how can careers in the sector be best promoted?

A reliance should be put on geospatial and GIS based learning at the earliest stages of academic studies in schools. As mobile technology evolves, younger generations are growing up with geoinformation and becoming more accustomed to it, perhaps without the knowledge and understanding of what they are using and how powerful it can be. Helping them to understand geospatial early on could lead to improved chances of steering more children into geo based careers.

Q4. Are there any publicly or privately-held geospatial datasets that are currently challenging to access or use or of insufficient quality, but which you or your organisation would find valuable if these issues could be resolved? Please explain why this would be of value, and how access/quality could be improved?

It would be of huge benefit to unlock more information from Land Registry's Title polygon dataset in terms of land ownership. As a Local Council we receive frequent queries regarding land ownership, and to be able to interrogate this dataset to identify who's responsibility a piece of land is would be a great time saver to resolve queries at the first point of contact. The existing web service feeds provide boundary information but with no valuable attribute information; this addition would be a significant benefit.

Q5: Do you anticipate that any changes will be needed to both the address data and the wider address ecosystem, to support emerging technologies? Please provide evidence of value to support any proposed changes.

Apart from greater ease of access by opening up address data under the OGL, I don't believe there are any fundamental changes required to satisfy emerging technologies.

Q6: How should the commission be looking to develop the UK's capability in Earth observation data, both technologically and to support an effective market?

This is an area I do not have knowledge or expertise in and cannot offer a reasonable answer.

Q7. Which new technologies should the commission focus on to provide new opportunities to process and exploit geospatial data for economic growth?

AI appears to be the technology which is leading current research and innovation efforts and would be an area to unlock for potential economic growth exploting geospatial data.

Drone technology for aerial imagery capture could be of significant importance particularly for areas around London and other airport regions which suffer set backs through air traffic control restrictions on conventional aerial flying surveys.

Q8. How can geospatial data and applications be used to support enhanced roll-out of future technologies?

This is an area I do not have knowledge or expertise in and cannot offer a reasonable answer.

Q9: What are the options for how public sector organisations could continue to invest in maintaining and enhancing our geospatial data assets?

Cuts in funding from central Government have made it harder for local Government to maintain service provision and investment in geospatial technology.
Any national initiatives could require investment through new burden funding much like the INSPIRE Directive to ensure public sector organisations are able to meet and adhere to any Government driven projects.

Q10: What areas of the underpinning geospatial infrastructure such as positioning technologies, including GPS and indoor positioning systems, and geodetic networks and frameworks to support them, should we be prioritising the development of, in order to support the emerging requirements for geospatial data?

This is an area I do not have knowledge or expertise in and cannot offer a reasonable answer.

Q11: What role should the private sector have in both the development and maintenance of the underpinning infrastructure and enhancing the UK's geospatial data assets?

Critical datasets maintained and developed by the private sector (i.e utility networks) should where possible be available for use for public sector organisations via reasonable licensing agreements to improve the quality of their own data assets and to better inform for the provision of public services.

Q12. Do you face challenges when working with geospatial data from across the public sector? If so, what are they and how could value be better released? Are there any technical remedies or standards that could be adopted to improve the interoperability of geospatial data? Please provide supporting evidence of what these remedies could help to accomplish.

I have found the access to geospatial data across the public sector to have significantly improved in recent times, particularly from central public organisations like the Environment Agency via WMS / WFS data feeds and opening up datasets via the OGL. The challenges generally come from local authorities who are at varying stages of meeting the INSPIRE regulations and therefore are offering different levels of geospatial data access. The standards to adhere to are mostly in place, it is more a question of encouraging those organisations to meet the standards, as different levels of willingness / resource availability mean there is still a disparity across the public sector.

Q13. How can the Geospatial Commission act as a more effective customer for geospatial data on behalf of the public sector?

Communication is a key element to ensure that public sector organisations make the most use of the datasets available; an improved awareness of what datasets are consumable is imperative. For example the work the APGB has been doing is extremely important and relevant to local Authorities, but the awareness of the web services providing the data may not have been too widespread. Rather than local authorities having to sign up and finding out these services are available, it would be more beneficial to ensure all local authorities have ready to go accounts with direct service links from the start to promote and ensure they are being actively used.

Q14. Are there any additional geospatial datasets, from the other partner bodies or other sources, that the public sector would derive significant benefit from having access to, that might have novel and valuable use cases? What would that access look like?

Referring to question 4, a more detailed Land Registry title polygon dataset would find huge benefit in the local authority spectrum. The current web service offerings are of great use, but additional attribute information to include title numbers and land ownership details would be of great use.

Q15: How can we best develop a single UK strategy, ensuring alignment between the individual strategies across the UK while still allowing for regional variations?

There needs to be a common framework to adhere to in terms of data standards, schemas etc for core information. Ensuring the core aspects of geospatial data are covered, those variations / differences required for specific areas can be satisfied without incurring significant interoperability issues.

Q16: How can we best ensure effective local authority coordination and sharing of best practise, using location data to better deliver public services?

Similarly to question 15, a common framework should be agreed upon so that data irrespective of which local authority it comes from will be structured in the same way. The Surrey Digital Services developed a Surrey wide planning hub which took planning information from across the County and published it onto a centralised web application basing it on LGA's planning application schema. Removing physical boundaries from data would improve public service delivery, and working towards a common standard again means that data can be interpreted and used irrespective of where the data resides in the UK.

The establishment of an online community forum specifically for local authority users could be beneficial; the Knowledge Hub does have forums for this but these tend to be found out through word of mouth – active promotion and awareness via the Geospatial Commission could engage more geospatial users around the UK and open up better and more informative discussions online.

Q17: As a result of this analysis, we are prioritising the exploration of possible initiatives in the high-value categories identified:

- **property and land**
- **infrastructure and construction**
- **mobility**
- **natural resources**
- **sales and marketing**

What are the existing or potential geospatial applications which could be scaled-up or developed in order to capture economic value? (We would particularly welcome responses from industry and other bodies engaged in these sectors.)

This is an area I do not have knowledge or expertise in and cannot offer a reasonable answer.

Q18: Are there any other areas that we should look at as a priority?

The list appears to cover the key areas for potential economic value utilising geospatial data.

Q19: What are the main potential private and public sector innovations that will rely on the use of geospatial data to rollout, and are there corresponding regulatory challenges?

Autonomous vehicles and AI / VR are areas that will heavily rely on geospatial data which could pose regulatory challenges as they are new fields of innovation.

Q20: How best can we make the UK's presence in the international geospatial world more visible?

Internationally visibility will coincide with partnership working and collaborating with other international organisations on comparable projects. To maintain the standing the UK has in the international geospatial community, we need to continue to work on international programmes to show that we are focused on globally improving the geospatial economy to benefit not only those in the UK but across the World.

In terms of data, the UK's efforts to open up much of our public sector geospatial data must display a desire to share and encourage information to be freely used, and this must continue to ensure the UK's presence as a global leader within the geospatial industry.

Q21: Where should the UK be looking for points of comparison overseas? Who are the other international exemplars? What best practice is being modelled overseas that we can learn from?

Open address data is one area that should be looked at and specifically Denmark appear to have seen significant benefits in opening up their national address database. Addressing has been a long withstanding bone of contention but the benefits that can be realised make it an area to continue to investigate.

Thank you for your time in completing your response to our call for evidence.

1. Is the Geospatial Commission view of the geospatial data types (Geospatial data, Positional data, Geospatial identifiers and Geospatial services) accurate, if not what should be included or excluded from this?

“Geospatial Services” is not really strictly a data type however there are offerings that deliver “data as a service” e.g. through an API. Positional data could be more appropriately labelled as “Ground Truth Data” or “Location Information Data” as positional data terms is generally related to only geographic coordinates of a location.

2. In addition to current government policy, what are the areas of geospatial skills where the Commission could best focus to help ensure the necessary capability within the UK for the future?

The UK has some of the leading researchers in the geospatial domain. However, schemes such as DSA accelerator scheme run by the GDS for general machine learning can be adopted and run specifically for geospatial domain applications.

There is a lack of qualification, understanding and appreciation of geomatics as whole (i.e. art of possible/challenges/capabilities) at SCS and director level in govt. There are many government organisations with enterprise spatial infrastructures containing critical geospatial business data, where the senior leadership would benefit from having greater awareness on geospatial strategy and techniques, innovation and geospatial capabilities. Developing geospatial skills in the directors/SCS cadre should be an area for the Commission to focus on.

The European Commission has the EC Science Hub (Joint Research Centre) which is where the majority of its geospatial science and technical capability sits in the EC. It is the EC’s JRC that has been responsible for introducing Earth Observation into the UK and the agriculture policy over the past 20yrs, long before Defra had an Earth Observation Centre of Excellence or UK establishing its own space agency. When we leave Europe, the UK won’t have the JRC and its capabilities, therefore the Commission should consider setting one up in the UK to fill the gap.

3. What are the geospatial skills needs and gaps in your organisations, how can these be most effectively addressed, and how can careers in the sector be best promoted?

Recruitment of geospatial practitioners in government is difficult. GRS and gov HR departments don’t fully recognise and understand the profession yet. We are unable to attract middle managers from the private sector (in to the GI profession) into government. Despite many UK universities offering geospatial courses, we don’t attract applicants that have studied at UK universities, which suggests that government recruitment of UK graduates isn’t working. E.g. Fast Stream at Careers Fairs is attracting generalists not geographers.

The gap or challenge is finding people at HEO/SEO that have been in geospatial technical roles and can work with the GI data and technology, but also have managerial/leadership,

business delivery /analysis skills and competencies. All too often, an appointed GI analyst nearly always remains a GIS analyst, whereas they could progress on to more senior roles in GI Architecture, GI Business Analyst, Data Scientist or Manager etc. So the career pathway beyond GI Analyst should be an area of focus.

4. How should the Geospatial Commission prioritise which geospatial datasets they target to increase access? Please provide evidence of why this would be of value, and how access or quality could be improved?

The rural land parcel data (digital map of agricultural land) that is created and maintained by RPA/Defra is a key asset that is under-exploited. It is tightly coupled to Ordnance Survey Mastermap and thus subject to PSMA rules and restrictions. It is used extensively across the public sector (central and local govt), but not much in the private sector. By making the rural land parcel data open will enable the agricultural industry and agri-tech sector to exploit the data. For example, farmers will be able to us the data in their day to day business with farm management software and in precision farming.

At the RPA, we have often felt that the lack of regular supply of “Ground Truth Data”, (referred as “Positional Data” in the document) limits the UK’s ability to undertake national remote sensing campaigns, produce classification products or maintain a continuous monitoring regime of urban and agricultural geography. We also regularly receive FOI requests by private sector organisations, universities, research institutes to ask for the data that the RPA has collected from its inspections. Equally, there are other organisations across the Defra group and other organisations who also collect ground truths. The answer is a coordinated “National Ground Truth Layer Service” capture programme could be established with help from the Commission, outputs of which can be made available to everyone, particularly the private sector who want to develop earth observation data products but can’t because the ground truth data is not accessible.

5. Do you anticipate that any changes will be needed to both address data and the wider address ecosystem to support emerging technologies? Please provide evidence of value to support any proposed changes.

We speculate that robust data quality checks and collection techniques would be critical for some of the emerging technologies. For example, there is occasionally news of vehicles stuck in narrow lanes because the sat nav is not fully aware of the local road environments. Such mishaps can be avoided by careful collection and use of local context.

6. How should the Commission be looking to develop the UK’s capability in Earth Observation data, both technologically and to support an effective market?

The UK has a reasonable coverage of the downstream EO data market so the deployment or joint-ownership of our own satellites i.e. upstream sector would significantly boost the UK’s capability to provide bespoke EO data services.

Secondly, the military and national security sector possess technologies and capabilities that would benefit the civilian sector if there better collaboration. Releasing some of this

capability and innovation, or the military sharing some of its best practice would help the civilian sector overcome some of it challenges.

7. Which new technologies should the Commission focus on to provide new opportunities to process and exploit geospatial data for economic growth?

The commission has already identified mobile positioning technologies, and geodetic networks, which in our view is relevant for a wide variety of application areas.

8. How can geospatial data and applications be used to support enhanced roll-out of future technologies?

Use of geospatial data and applications could be used to model the scope and impact of the future technologies. For example, information on road networks can be used to model the impact and feasibility of (semi) autonomous vehicles.

9. What are the options for how public sector organisations could continue to invest in maintaining and enhancing our geospatial data assets?

The requirement to comply with mapping guidance (for Common Agricultural Policy) by the European Commission has driven RPA/Defra to maintain a very high quality asset and capturing process of geospatial datasets. Given that the new agricultural policy post Brexit and ministerial desires are to move UK away from extensive use of geospatial data and technology to maintain mapping on a national scale, RPA/Defra would lose the incentive to maintain and enhance the rich geospatial datasets (i.e. hedge data, land data, crop data, common data) on a national level. Therefore, a similar incentive would have to be set up, preferably linked with some subsidy scheme for added regulatory dependency.

Conversely the rest of Europe is going in different direction for Agriculture, whereby other member states are moving to a full satellite based monitoring regime that will remove the need for on the ground farm inspectors. If England adopts an agriculture policy that is so environmental and less agricultural that doesn't allow for the use of geospatial technology and remote sensing inspections, then UK farmers will be disadvantaged and subject to more red than their European counterparts. In the interest of the food and agriculture industry, the Commission should influence the Agriculture policy making to ensure that UK does not regress back to the beginning of the 1990's before we started using geospatial for Agriculture and Food policy.

10. What areas of the underpinning geospatial infrastructure such as positioning technologies (including GPS and indoor positioning systems) and geodetic networks and frameworks to support them should the Geospatial Commission prioritise the development of to support the emerging requirements for geospatial data?

The Dutch Agriculture industry is the exemplar when it comes to geospatial infrastructure. The Dutch farmers are using more precision farming and remote guidance tractors because they have a more complete and better RTK GNSS/GPS network. The UK doesn't have a common standard and open base-station RTK network, which deters precision and

smart farming. Farmers have to buy their own base station or subscribe to one (if there is one available nearby).

Also, the agriculture industry wrestles with different manufacturers' using different GPS standards. For example, an RTK network for Trimble GPS doesn't work with John Deere or Topcon products. If the agriculture industry is to move forward in the digital era, there needs to be some harmonisation of standards. Imagine if you bought a second hand car and its sat nav didn't work because the previous owner subscribed to or lived in an area that received a different signal.

11. What role should the private sector have in both the development and maintenance of the underpinning infrastructure and enhancing the UK's geospatial data assets?

As described above, the private sector (machinery manufacturers RTK signal providers) could all adopt the same standards. Remove the 'VHS versus Betamax' scenario.

Private sectors could work with each other to ensure that the capture plan for their products complement thus ensuring the data quality is consistent, and provide robust , multi-modal and scalable distribution of the geospatial products .

12. Do you face challenges when working with geospatial data from across the public sector, and if so what are they, and how could value be better released? Are there any technical remedies or standards that could be adopted to improve the interoperability of geospatial data? Please provide supporting evidence of what these remedies could help to accomplish.

The RPA is required to maintain the mapping of land parcels up to date, and none of the mapping is expected to be based on information (e.g. OS MasterMap, APGB Aerial Photograph) older than 3 years old. Therefore, the knowledge of currency e.g., the aerial photograph capture date or the field survey date that underlies some of the public sector data e.g. OS MasterMap and APGB Aerial Photographs is very important to the RPA operational business processes for surveillance GI data maintenance. However, these organisations run their data capture campaigns independently, even though in some cases they are linked to each other. It would be useful if the respective organisations can harmonise the data collection such that they complement each other. For example, OS, APGP, and EA all keep their planes in the same hanger at the same airport. Despite being in the same hanger, all three planes (funded by UK govt) have their own flight plans that are not aligned in any way. If they were aligned, the currency could be reduced down to 1.5yrs-2yrs.

13. How can the Geospatial Commission act as a more effective customer for geospatial data on behalf of the public sector?

The commission could conduct a wide survey of geospatial needs for public sector and identify overlaps and scope for enhancements in the quality of geospatial data currently procured by the public sector.

14. Are there any additional geospatial datasets, from the other Partner Bodies or other sources that the public sector would derive significant benefit from having access to, that might have novel and valuable use cases? What would that access look like?

There is probably a vast amount of socio-economic, infrastructure and planning data that is maintained by the public sector organisation but it is unavailable for various reasons. There have been several projects in the past regarding data discovery portals could be set up e.g. through data.gov.uk

15. How can the Geospatial Commission best develop a single UK strategy, ensuring alignment between the individual strategies across the UK while still allowing for national variations?

There could be little value to be gained by attempting to build a so-called single UK strategy because national variations may inhibit adoption of such a policy. For example, the Agriculture and Environment sector is a large geospatial use case that is already devolved and adopting different strategies.

Conversely, when we leave Europe, will a replacement INSPIRE be required, or will we continue to adopt the principles of INSPIRE in the UK? Eitherway, this is where a strategy might be useful to replace previous EC strategy and policy such as INSPIRE.

16. How can the Geospatial Commission best ensure effective local authority co-ordination and sharing of best practice, using location data to better deliver public services?

The inclusion of local authorities within the APGB framework is a good start. The planning permissions department of local authorities could be asked to enrol in a centrally run government mapping platform (e.g. one baselined against the MasterMap or Land Registry), and made available to the public.

Going forward, there are some other member states that have adopted an Open Street map /Wikipedia approach to national mapping. UK could appoint a central statutory coordination unit to oversee the administration of standards policies to be used in updating Mastermap. Devolve the update of Mastermap to the multiple public sector mapping teams across government, e.g. HMLR, EA, Councils, RPA, FC, etc. With governance, standards and SLA's in place, multiple different bodies could be authorised to update an open Mastermap, like Wikipedia or Open Streetmap.

17. As a result of analysis the Geospatial Commission are prioritising the exploration of possible initiatives in the high-value categories identified (property and land, infrastructure and construction, mobility, natural resources, sales and marketing). What are the existing or potential geospatial applications which could be scaled up or developed in order to capture economic value?

The following suggestion doesn't necessarily create new value but can potentially offer significant cost-savings and generate information that would be useful for policy. Much of

the property related information available online doesn't reveal information such as age and details of the property (e.g. conditions etc.). Providing these information would unlock opportunities for policy makers and private companies to assess areas of regeneration or potential hazards e.g. poor building materials (like fire resistant cladding). Similarly, there is lack of information on the quality and design of infrastructure such as highways in a format that can be publicly available e.g. equivalent of google streetview.

18. Are there any other areas that they should look at as a priority?

NO

19. What are the main potential private and public sector innovations that will rely on the use of geospatial data to roll out, and are there corresponding regulatory challenges?

(Semi) Autonomous cars, AI driven internet search queries that use a geographical context (e.g. about traffic, weather, shopping etc.). There would be no new regulatory challenges and existing mechanisms such as GDPR, IPR and others would address privacy concerns.

20. How best can the Geospatial Commission make the UK's presence in the international geospatial world more visible?

At present, the UK's presence in the international geospatial world mainly comprises of academics and commercial organisations with an international outreach e.g. the Ordnance Survey. This has been possible because of existing international collaboration programmes and fellowships. However, there is a vast amount of commercially valuable ideas being developed, and geospatial expertise available within the government departments and public sector organisations. These organisations do not have the opportunity to expose their work internationally. Geospatial Commission should look into setting up international knowledge and expertise exchange programmes at government levels and funding mechanisms for experts to participate in international events. This will be particularly relevant post-March 2018 when such existing mechanisms with EU will be unclear.

21. Where should the UK be looking for points of comparison overseas? Who are the other international exemplars? What best practice is being modelled overseas that we can learn from?

As mentioned earlier, the Dutch are considered exemplars for Agriculture and Agri-tech that use geomatics.

While, the geospatial data, software, and hardware domains are fairly stratified and comprises of a pre-existing heavy weights who dominate in the respective fields. For example, from the USA, ESRI, DigitalGlobe, and other small companies have the largest share of geospatial, and very high resolution satellite images market, while from Switzerland and Germany, Leica and others have the largest share of survey instruments and software. In others word, the other countries have focussed on a specific domain of the geospatial ecosystem and invested heavily into it. The geospatial services industry is

however quite fragmented and contains abundant opportunities for UK start-ups, franchises across the world.

Geospatial Commission: Call For Evidence Response Questionnaire

Please submit your completed questionnaire to:

geospatialcommission@cabinetoffice.gov.uk.

Clearly title your email *'Call for evidence response'*.

Call for evidence - three key themes

We have identified three high-level themes that could help our approach to setting a strategy which are as follows:

1. **Supporting innovation in the geospatial sector**, exploring how to secure cutting edge skills, the right access to data, and opportunities from emerging technologies for the geospatial sector itself
2. **Enhancing the UK's geospatial assets,** looking at how best to align interests, avoid duplication, and instill best practice across the whole public sector
3. **Driving investment and productivity in geospatial applications**, asking in which wider sectors the most value lies from better exploitation and use of geospatial data, in the UK and internationally

Our questions

Q1. Is our view of the geospatial data types accurate? If not, what should be included or excluded from this?

This is broadly a good view of geospatial data types, assuming that 'geospatial services' consist of augmented data products, such as geodemographic classifications and census information. We would encourage the inclusion of (spatio-) temporal data. Using additional examples for clarity would also be beneficial as it is easy to confuse Geospatial Data and Positional Data at present. For example, we take Geospatial Identifiers to include addressing, postcodes and Output Area Boundary codes. We take positional data to be the location of a store or asset. These elements would benefit from having a more constrained definition (especially geospatial identifiers).

Q2. In addition to current government policy, what are the areas of geospatial skills where the commission could best focus, to help ensure the necessary capability within the UK for the future?

Improvement in geospatial skills comes from two main areas. Firstly, training in schools and universities. We believe geospatial should be a core part of non-geography degrees (computer and data sciences, as well as other social sciences). This could and should start further down the levels of education. There is also scope for re-introducing geospatial data and analysis to many qualitative geographers. Many of these techniques should include basic skills with linking geospatial data and positional data and then using visualisation tools to analyse, present and create products from these data sets.

Away from university, there is a huge gap in widening awareness of spatial and the benefits that it can bring within business and other organisations. Very few people understand even basic information such as being able to see an organisations' assets on a map. There are many relevant use cases that are not yet exploited or advertised, and promoting how geospatial can add value to organisations should be more widely promoted, particularly with reference to applications and the types of decisions that are not possible without geospatial data and techniques. This is not geospatial skills training per se, but a wider education for understanding the applications. There is also perhaps a gap in non-spatially trained professionals with regards to the collection and recording of spatial data, but this might not be the best use of the Commission's resources and may be better placed within organisations on specific projects.

Q3. What are the geospatial skills needs and gaps in your organisations, how can these be most effectively addressed, and how can careers in the sector be best promoted?

The largest gaps lie in growing an organisation's understanding of where their assets are and the types of interaction customers and people have with the services provided. In our experience, there is a large gap within the IT/BI sector where geospatial knowledge can be limited. This gap is also relevant amongst the business analyst community whose focus tends to be on what happens within a store (or other asset) and not on the changes and real world behaviours outside it. These two areas – almost an introduction to GIS – would be a good focus of the wider acknowledgement of the industry.

Within those who have some knowledge of the industry, are skilled or partially skilled, there is a very broad range of expertise and sector knowledge. It is hard to apply training for general geospatial skills (e.g. remote sensing is a very different skill set to spatial interaction modelling). There is good provision for both core skills and more technical skills from a variety of vendors and educators (for example GIS BSc/MSc's), however the industry might benefit from a series of MOOCs more tailored to specific subject matters (for example, there are many MOOCs on Data Science on the various platforms (edx, coursera, udacity), but few on Geospatial).

An understanding of ethics and privacy, and the challenges when adding a spatial element to data, can also be overlooked. There are many big questions that are yet to be answered here, for example, just because we can track someone's movements through mobile phone data, should we? Do we all know that around four timestamped locations can lead to identification of a person? How can we reconcile this with needing to innovate? Accordingly, there could be training in this area, as well as publishing of geospatial datasets to a non-disclosive standard. This is an area that the national statistics bodies have great experience of but is rather limited outside. Increased levels of awareness and understanding of how open data can be published in this area and then catalogued and understood for the creation of value is important. This includes all aspects from a basic legal understanding of creative commons to technical mechanisms for accessing data sets.

There is often a large gap when it comes to telling stories with maps, and even when spatial analysis forms part of a project, the exclusion of spatial story telling is often found in presenting results. This skill set might also go some way to helping the exposure of geospatial analysis.

Q4. Are there any publicly or privately-held geospatial datasets that are currently challenging to access or use or of insufficient quality, but which you or your organisation would find valuable if these issues could be resolved? Please explain why this would be of value, and how access/quality could be improved?

- Addressing and UPRNs (discussed in more detail later).
- Issues related to devolved and local governments (again discussed later).
- Wide (cost effective / free) access to OS Mastermap (Inc NI), which prevents full adoption of GeoBIM.
- Ratings Lists by Country.
- Access to Novel Data Sources (Card Data, Mobile Phones) are prohibitively expensive on a large, UK wide-scale. These behavioural geographies would be hugely beneficial for a wide range of applications if made more easily accessible.
- Clean and easily consumable open data such as GP-Pharmacy Prescribing Data (inconsistencies between reference files), Consistent Train, Tube, Light Rail Station locations and Passenger counts (e.g. some miss a spatial reference for a station).
- Land Registry Polygons linked to UPRN.
- POI data for GB and NI in a consistent format.
- Aggregated but spatially referenced data from HMRC.
- Urbanity at Local Authority Level for the whole UK.
- A nationally sourced and provided drive time/travel time network, which is able to provide a consistent view of the time it takes to get from one place to another. This would combine the ITN, Average Speeds from actual journeys, as well as pedestrian routing. Cost of entry can prevent a

consistent source being used (and therefore different results) and has many applications within transport, retail, health and beyond.

The majority of these datasets are in existence, but are prohibitively expensive (or bureaucratic) to access from a license perspective (and occasionally but not always a processing perspective).

We should also recognise some of the great work being done to simplify data access by both the ONS Geography Portal and Research organisations, such as the Consumer Data Research Centre.

Q5: Do you anticipate that any changes will be needed to the both address data and the wider address ecosystem, to support emerging technologies? Please provide evidence of value to support any proposed changes.

A primary focus should be on establishing an open and complete form of spatial addressing dataset, including land reg polygons, UPRNs, grid refs, and any other related linking fields. This will enable organisations to maximise the spatial accuracy of both asset registers and also help service delivery. For example, no more missed deliveries due to erroneous locations or sat nav locations. A single consistent framework for this would be hugely beneficial.

Q6: How should the commission be looking to develop the UK's capability in Earth observation data, both technologically and to support an effective market?

EO data has many potential benefits, which are often overlooked due to the overhead of processing and maintaining the data which is resource heavy and often duplicated across multiple organisations. Providing pre-processed data sets (perhaps cloud hosted) containing indexes against which particular data sets can be identified, publishing this data in an effective and easy to consume manner could help to open up applications such as:

- AI questions – field boundaries could be mapped and visualised in terms of the change through time and the impact on local communities.
- Deforestation – this is a key sustainability concern and relates to SDG 15. The ability to monitor deforestation to ensure that we are sourcing sustainably is key. This can track progress and indeed progress on tree planting as well as deforestation to ensure total impact can be quantified.
- Fishing – using data to monitor locations and routes of vessels is an important tool to ensure that supply chains are legally compliant.
- Asparagus shipping – tracking container vessels and internal data from these containers has enabled us to move products from air freight to sea freight meaning more efficient and sustainable transport. More value can be unlocked through this. It allows the supply chain to plan better and reduce food waste.

Q7. Which new technologies should the commission focus on to provide new opportunities to process and exploit geospatial data for economic growth?

Develop a standardised way of finding places in real life. This would include all addressing items in Q5, perhaps with more precision, such as what floor of an apartment block an address is located on (helping service delivery in all sectors from retail to health and emergency services).

The creation of a (single) portal to access or redirect users to all data would be hugely beneficial (discussed more later). Alongside this would be a set of standards and indexing for ease of search and better traceability back to original sources of data.

From a practical perspective, improvements would also be gained by contributing to some of the technologies (e.g. open software, open geospatial consortium) to improve ease of use, spatial data storage, better traceability, spatial algorithms (e.g. more efficient spatial matching etc.).

Emerging technologies such as sensor tracking, tracking of goods, traceability of products would be another useful area of focus. For example, could there be a global traceability system for efficiency in food and goods. The efficient combination of sensors and geospatial data would have applications in ecosystem mapping, pollution prevention and conservation, and current technologies have a relatively high entry cost with a need for many specialists.

Q8. How can geospatial data and applications be used to support enhanced roll-out of future technologies?

Everything that happens, happens somewhere. The integration of standardised addressing into future technologies (as discussed previously) will help solve many issues. Geospatial also has a role to play in the localised roll-outs of new technology from a logistical/organisational perspective, as well as supporting in the ongoing management and maintenance (and gradual improvement of) existing technology.

Q9: What are the options for how public sector organisations could continue to invest in maintaining and enhancing our geospatial data assets?

The centralising of (or centralising access to) data could be invested in or maintained by small charges to those who make planning applications. For example, the digitising of new roads by the OS could be funded in part by those building those roads.

There is also a role for policy enforcement (and fines), which geospatial be potentially be used for.

Q10: What areas of the underpinning geospatial infrastructure such as positioning technologies, including GPS and indoor positioning systems, and geodetic networks and frameworks to support them, should we be prioritising the development of, in order to support the emerging requirements for geospatial data?

One area could be LIDAR data, making sure that this is more precise, more frequently updated, more open and easier to use. Pre-processing and packaging in a useable format is key. The history that a long term data set would create will be useful for understanding change in environment in a range of domains, such as building management, planning, and agriculture. GPS, in our view is relatively established and sufficiently accurate for most of our applications. IPS, and the multitude of approaches, has a relatively limited range of applications, but efforts could be made on the interlinking of GPS and IPS.

Q11: What role should the private sector have in both the development and maintenance of the underpinning infrastructure and enhancing the UK's geospatial data assets?

Most organisations should be able to easily develop asset registers (e.g. Store A is located here). There is no reason why information about such assets should not be shared with UPRNs to help other conduct analysis of what is where. There may also be a role to play for the private sector for supporting geospatial data and analysis for the public good, however this can be challenging from a resource perspective, as well as a host of issues related to coverage, bias, and representation within private sector data.

Q12. Do you face challenges when working with geospatial data from across the public sector? If so, what are they and how could value be better released? Are there any technical remedies or standards that could be adopted to improve the interoperability of geospatial data? Please provide supporting evidence of what these remedies could help to accomplish.

One of the main issues we face is that of devolved governmental data. This manifests itself in a variety of issues such as different methods, different formats, different levels of spatial coverage, and different release dates. For example, the staggered release of census data from each nation (especially with latterly released products such as workplace zones) remains problematic. Whilst we do not expect all data to be the same (nor is this the best use of efforts in the short term), consistency of release dates would be valued. More importantly, ease of access (a single point) and clarity of the most up to date data would be beneficial. Data formats are largely workable, for those with the right tools and knowledge, but this is not the case for all users and could be a limiting factor.

Q13. How can the Geospatial Commission act as a more effective customer for geospatial data on behalf of the public sector?

We agree with the aims stated above. The effective procurement and simplification of this range of spatial data will be key to efficiencies across the public sector. Thought could be given to whether some of these also be used amongst the private sector, who face similar issues to the public sector. Many organisations are buying the same data from many different suppliers.

Q14. Are there any additional geospatial datasets, from the other partner bodies or other sources, that the public sector would derive significant benefit from having access to, that might have novel and valuable use cases? What would that access look like?

Geotemporal Payment Card Data – for use in economic statistics – where and when is economic activity growing and shrinking? The ONS are working towards elements of this from large retail organisations, but some more detailed geospatial measures may be obtainable from banks and card operators.

Q15: How can we best develop a single UK strategy, ensuring alignment between the individual strategies across the UK while still allwoing for regional variations?

Create as many common standards as possible with regards to data formats, timescales of release, coverage scales/geographies. However, the most useful development will be a single portal. Where data are readily combinable (e.g. collected to same specification), combine it. Where not, send the user to the respective datasets. Reducing the hours spent trawling each stats office website will be very valuable.

Q16: How can we best ensure effective local authority coordination and sharing of best practise, using location data to better deliver public services?

An area that would provide large improvements would be the co-ordination of the planning system, being able to more easily track planning applications accross multiple local authorities.

Q17: As a result of this analysis, we are prioritising the exploration of possible initiatives in the high-value categories identified:

- **property and land**
- **infrastructure and construction**
- **mobility**

- **natural resources**
- **sales and marketing**

What are the existing or potential geospatial applications which could be scaled-up or developed in order to capture economic value? (We would particularly welcome responses from industry and other bodies engaged in these sectors.)

Many of these use cases offer large potential value to both business and the wider public. Within the property and land category, the opening up of an easy and free to use property search function (ownership, planning, flood etc.) under the guise of e-conveyancing has the potential to create considerable savings in house and property purchases, both monetary and the time taken to complete purchases. We can also see value in supporting optimal routing for utilities.

Some particular use cases, and potential projects, that it would be good to focus on within the themes above would be:

- Construction project timelines and land registry completion data, which would help to establish when new housing developments are complete and occupied, including estimating how many new homes are occupied at different stages of the development. This would be particularly useful for planning services, from both a retail perspective and health, schools, etc.

- Within this domain, increasing GeoBIM adoption will help with better planning and design of new buildings. Their setting within the environment will benefit public consultations and the planning process and may also create efficiencies in preparatory work stages.

- Mapping of end-to-end supply chains and the tracing of products through the supply chain is already done in some sectors, but innovations might be gained through the examination of new technologies such as block chain and RFID tagging. A worldwide geocoder could be an important part of this. Better understanding the full extent of global food production will become increasingly important with climate change from both a policy and practical perspective.

- There is large potential within the optimisation of deliveries using a combination of both better and more open addressing and more effective and accurate journey time networks. Better understanding of journey times (through more accurate/real data and better route planning at complex junctions) will help to better plan deliveries, including optimising staffing levels and delivery slot availability for consumers. Open addressing is obviously a key part of this.

- Precision Agriculture – this is currently undertaken well with machinery but there are vast areas of improvements for application technology and combining multiple data sets. For example, crop development/quality with field boundaries and tractor movement. There are also multiple uses in

enforcement of regulation that is currently in its infancy.

Many of these use cases are very possible but are limited by the prohibitive costs of entry at large scales.

Q18: Are there any other areas that we should look at as a priority?

- Health (e.g. access to services; location of services; health outcomes)
- Transport network (spatio-temporal datsets on commuting and congestion)
- Energy efficiency (e.g. small area household energy consumption)
- Regulation and Equity (e.g. small area energy tarrif / switching)
- Regional Economies and Resilience (non-disclosive HMRC indicators of activity)
- Property & Land (vacant / brownfield land register, Local Plans housing register)
- Tourism
- Climate change

Q19: What are the main potential private and public sector innovations that will rely on the use of geospatial data to rollout, and are there corresponding regulatory challenges?

- GeoBIM will require access to high-precision map feature data so that buildings may be placed accurately in their environment e.g. open access to OS Mastermap and/or Land Registry Polygons. The current charging model for OS and Land Registry data is likely to inhibit the widespread uptake of GeoBIM.
- Addressing and ease of finding places will require an Open Address Register which brings together address, position and related spatial references (e.g. UPNR). The current situation between Local Authorities, Ordnance Survey and Royal Mail stifles innovation in this sector.
- Agriculture – precision agriculture, driverless farming, satellite imagery and linkage to farm payments post Brexit, also potential to use to enforce regulation.

Q20: How best can we make the UK's presence in the international geospatial world more visible?

- Creation of an international intergovernmental conference on geospatial innovation and standards.
- Setup a new division in ONS dedicated to Geospatial Statistics. This could be used as an exemplar internationally.
- Setup/fund/support interenational disaster response charities (e.g. from international development fund) such as MapAction, CrowdResuce, Humanitarian Open Street Map, Red Cross etc.

Q21: Where should the UK be looking for points of comparison overseas? Who are the other international exemplars? What best practice is being modelled overseas that we can learn from?

We believe that the UK should be seen as an exemplar on internationally recognised standards, and this may be something to work with the BSI, ISO etc. We have limited experience of working with international geospatial data commissions, although some experience of working with international data. From the perspective of data access, the INSPIRE portal, ONS Geography Portal and Irish geoportal are all easy to use and find data, as are some of the off-shoots of the UK big data research network, but links away from these locations can sometimes be problematic. From the perspective of raising awareness, much of the best work that we have seen comes from the private sector, often large or SME geospatial companies such as ESRI, Carto and Stamen who present applications (albeit from a promotional perspective). We have limited experience of large agencies trying to bring together a wide variety of partners and facilitate innovation in the space.

Thank you for your time in completing your response to our call for evidence.

Any questions, please get in touch with the Geospatial Commission via geospatialcommission@cabinetoffice.gov.uk

Geospatial Commission: Call For Evidence Response Questionnaire

Please submit your completed questionnaire to:

geospatialcommission@cabinetoffice.gov.uk.

Clearly title your email *'Call for evidence response'*.

About you and your organisation

Name	[Text redacted]
Organisation	Satellite Applications Catapult
Job title	[Text redacted]
Address	[Text redacted]
E-mail	[Text redacted]
Telephone	[Text redacted]

Please select which of the following best describes you as a respondent:

Respondent	**Please mark with a X**
Academic	
Business representative / trade body	
Central government	
Charity or social enterprise	
Individual	
Legal representative	
Local government	
Large business (over 250 staff)	
Medium business (50 to 250)	**X**
Small business (10 to 49)	
Micro business (up to 9)	
Other - please state	Independent non-profit technology innovation company.

Call for evidence - three key themes

We have identified three high-level themes that could help our approach to setting a strategy which are as follows:

1. **Supporting innovation in the geospatial sector**, exploring how to secure cutting edge skills, the right access to data, and opportunities from emerging technologies for the geospatial sector itself
2. **Enhancing the UK's geospatial assets,** looking at how best to align interests, avoid duplication, and instill best practice across the whole public sector
3. **Driving investment and productivity in geospatial applications**, asking in which wider sectors the most value lies from better exploitation and use of geospatial data, in the UK and internationally

Our questions

Q1. Is our view of the geospatial data types accurate? If not, what should be included or excluded from this?

We support the categories and descriptions captured with the following considerations:

- **Presentation in the current format is an oversimplification** due to the non-linear nature of adding value to geospatial datasets. A geospatial 'product' can simultaneously belong to multiple of the described data types depending upon user case and application.
- **Temporality** is an unavoidable perspective that doesn't seem to be considered within the definitions and is integral to any geospatial data type.
- **Earth Observation** image (raster) datasets are assumed to have been considered within the definition and fall across the geospatial types depending upon their user case.

Q2. In addition to current government policy, what are the areas of geospatial skills where the commission could best focus, to help ensure the necessary capability within the UK for the future?

The skills and technologies noted below are in high demand across the UK public and private geospatial sector.

Those in bold should be considered priority areas for policy intervention and investment.

- **Sensor Interoperability, Harmonisation and Data Fusion**
- **Geospatial Database management**
- **Business-led deployment of Deep Learning techniques (Convolutional & Recurrent Neural Networks) upon Geospatial Data.**
- **Workflow optimisation (Scaling and Clustering)**
- Building Information Modelling (BIM)
- Market (user case)-driven Earth Observation application development.
- Geospatial Intelligence Provenance: Uncertainty Modelling and Error Propagation

- Statistical Modelling and Inference
- Feature Extraction, Object Detection and Classification upon Geospatial Data.
- 3D Geospatial Information Systems
- Geospatial-driven Augmented and Virtual Reality
- Geospatial standards (OGC, etc.)
- Cross-platform Infrastructure Deployment (Virtualisation and Cloud)
- User Centred Design
- Open Data, Semantic Web
- AI-assisted Crowdsourcing
- Open Source, community-driven Software Development (i.e. FOSS4G)
- IoT Exploitation and System Integration

Q3. What are the geospatial skills needs and gaps in your organisations, how can these be most effectively addressed, and how can careers in the sector be best promoted?

Ensuring that we proactively identify skills needs is something the Satellite Applications Catapult is ideally placed to achieve through its existing Partnership and Engagement team.

We combine use of permanent staff with building consortia as we have a need for representation of the full breadth of geospatial skills and competencies. Through our engagements over the past five years with more than 3000 organisations, there are recurring geospatial skills gaps that we actively work to address in collaboration with UK partners.

Geospatial-related roles that Satellite Applications Catapult and its wider partner ecosystem persistently struggle to recruit for include:

- **Geospatial and Earth Observation Specialists** with a core blend of geospatial, Earth Observation and Physics expertise for development of geospatial applications.
- **Computer Scientists** with core programming and big data management expertise, limited (but recognised) generalist geospatial expertise, and limited focus on geospatial applications.
- **Research Scientists** with core big data analytics expertise, particularly in design, development and deployment of contemporary machine learning and artificial intelligence, and limited generalist geospatial expertise, with a focus on efficiently evaluating and constraining product-related research questions.
- **Research Engineers** with a core blend of predominately big data management expertise and lesser machine learning and artificial intelligence expertise, with a focus on operationalising the delivery of researched products.
- **Product Managers** with sufficient blend of technical geospatial and non-geospatial market (user case) expertise to provide clarity and direction in translation of geospatial products and services into non-geospatial sector value propositions.

There is simply an insufficient number of people in the system with competencies across these geospatial roles. This current state is detrimental to UK innovation, competition and sustained economic growth. Sustained confidence in the UK geospatial skills base is highly uncertain in a post-Brexit environment.

Availability of skills associated with Research Scientist and Research Engineer roles are most scarce and therefore costly. Commercial advantages in leveraging these skills are limited to only large organisations that can subsidise their cost with existing profits or start-ups offering alternative incentives.

As all organisations face unprecedented data abundance challenges, there is an increasing requirement for geospatial to anchor the value and relevance of data as it is refined into information products.

Geospatial principles must be properly embedded into public and private sector organisations' product development and service delivery teams to improve service efficiencies and sustainable growth.

Addressing these skills gaps requires approaches that consider both geospatial and non-geospatial perspectives across the full career-cycle.

Satellite Applications Catapult, led through its Partnerships and Engagement Team, is a leading protagonist in use of established public and private sector mechanisms to address these challenges and promote careers in the geospatial sector; i.e.:

- Space for Smarter Government Programme (SSGP)
- 18 STEM ambassadors at Satellite Applications Catapult, though nationally many Primes support and encourage their staff to undertake these roles
- Annual and Summer Space Placements in INdustry scheme, 150 students placed in space businesses over 6 years.
- Researchers in Residence (RiR), Future Leadership Fellows (FLF), and Centres for Doctoral Training (CDTs), etc.
- Apprenticeships
- Satellites 101 training courses for cohorts of PhD students
- Supervision of numerous PhD, MSc, BSc students, including across government and industry.
- Charterships encouraging for industry-focussed progress recognition in later career stages
- Satellite Applications Catapult-led training courses for industry, gov., academia in priority areas (i.e. Sentinel-1 course, AI/Deep Learning course).
- Profiles of staff in Geospatial roles to inspire students.
- Hosting stands at national events such as New Scientist Live to promote geospatial careers.

Existing mechanisms alone are insufficient for addressing the specific skills gaps within the geospatial sector. These mechanisms provide only general frameworks, with no geospatial-specific skills development. They also only address skills gaps at an individual organisation, research group, student or employee level. Their exploitation requires overhead investment per organisation in engaging with the relevant initiatives to be beneficial. Each individual organisation must also have clarity in the skill gaps they are addressing. Organisations we see most experiencing skills shortages cannot afford to invest in these overheads.

A coordinated top-down approach across the whole of the UK should focus on priority skills that are lacking across the sector. This would greatly improve the effectiveness of addressing specific skill gaps and support per-organisation use of the existing mechanisms.

The Geospatial Commission is well placed to champion this type of approach. The coordination and implementation must come from other organisations such as Satellite Applications Catapult and UK Space Agency's (UKSA) Skills team.

A primary blocker to inspiring pursuit of a career in the geospatial sector is the disconnect between applications and techniques demonstrated / discussed within higher education and universities and those being operationalised within companies and public-sector services.

A further key challenge is that a career in the geospatial sector is miss-perceived as solely science focussed as opposed to offering equal (if not more!) market-facing career development opportunities.

Access to leading real-world examples throughout education would help to captivate the next generation of geospatial application developers and ensure that they obtain skills aligned with the requirements of leading public and private sector organisations.

Q4. Are there any publicly or privately-held geospatial datasets that are currently challenging to access or use or of insufficient quality, but which you or your organisation would find valuable if these issues could be resolved? Please explain why this would be of value, and how access/quality could be improved?

This differs in wording from Q4 in supporting Geospatial Commission Consultation document. Our response addresses both questions.

Q4 (pdf) How should we prioritise which geospatial datasets we target to increase access? Please provide evidence of why this would be of value, and how access or quality could be improved?

We suggest not to prioritise individual datasets but to focus on user-driven impact that can be evidenced through demonstrating the value of contemporary data access protocols.

The Commission can then focus on the much more pertinent question of which user-driven applications require minimal investment to evidence the necessary value to support policy intervention.

Satellite Applications Catapult and the organisations we work with share challenges in accessing geospatial datasets that we expect are common many responses, including:

- Duplicative and disparate sources for individual datasets
- Lack of 'discoverability'
- Spatial and temporal inconsistencies
- Limited or entirely absent metadata
- Inefficient file formatting

When delivering user-driven applications reliant upon Earth Observation datasets a similar set of even more potent 'big data' challenges must be addressed:

- Volume: satellite Earth Observation alone is the 3rd largest global data source.
- Veracity: complex quantitative measures with estimated uncertainty.
- Variety: wide ranging sensor types, platforms and measurements and even greater variety in providers.
- Velocity: sub-hourly and near-real time data streams.

These challenges are most pertinent when accessing public-sector datasets and we must overcome these to exploit ancillary geospatial datasets that are integral to realising value from satellite technology sources.

Specific examples of datasets with which we experience these geospatial challenges include**:**

- Copernicus Satellite Datasets (i.e. Sentinel-1, Sentinel-2)
- Government and Agency procured Aerial Photography
- Government and Agency procured Satellite Datasets
- OS Mastermap (and other products)

- Address Databases (i.e. revenue share across Royal Mail, OS)
- Environment Agency LiDAR
- UK Land Parcel Information System (LPIS)
- Land Registry Polygons
- Metrological Datasets
- Hydrological Datasets

Across the above examples and all other public-private geospatial datasets, **significant value would be gained from** the ability to access these datasets via a mechanism(s) that offers:

- Centralised Data Discovery
- Enhanced Search Capabilities
- Application Programming Interface (API) Access
- Real Time Updating and Live Streams
- Costing Models (i.e. Revenue Share, Pay-per-Use)
- Traceability and Provenance

This value would be realised as, for example:

- **Reduced development costs** (software engineering) associated with gaining data access from multiple access portals and API formats
- **Reduced maintenance costs** associated with hosting duplicative data access portal services
- **Reduced storage costs** associated with uncoordinated duplicative datasets
- **Improvement of existing value-added service**s (public and private sector)
- **Creation of novel value-added services** (public and private sector)

Work undertaken by organisations such as the Environment Agency, Office for National Statistics, Ordnance Survey and others, in simplifying and opening access to their geospatial datasets are recognised steps in the right direction.

Similarly, at the intersection of public-private-sectors, ad-hoc investments into initiatives such as Satellite Applications Catapult's SEDAS and Data Discovery Hub portals are additional steps in the right direction. With further coordinated investment with a long-term outlook they can provide a core and robust bridge for geospatial discovery and access to UK public-private geospatial datasets.

Progress however remains slow, uncoordinated, under-resourced and not resilient to technological change.

The Industrial Strategy Challenge Fund (ISCF) 'Space Data Revolution' Challenge provides a good example of where coordination across public and private sectors leads to a proposal that has potential to create a step change within the UK toward realising the economic benefits from fully exploiting Earth Observation capabilities, by allowing user-driven applications to be developed more easily by more organisations without the need for specialised expertise. **This is precisely the kind of initiative that we expect the Commission to be championing into government.**

Our response to Q12 covers in greater detail the value to be gained from addressing these challenges specifically in the public-sector and in Q11 we give examples of private-sector's involvement.

Assessing the 'quality' of geospatial datasets is highly subjective. It can cover everything from satisfying meticulous metadata requirements and giving complete geographic or temporal coverage, to geospatial attributes being representative, accurate or precise.

In our experience, the most critical component to geospatial data quality is having confidence in the provenance of those data.

The advantages of rich metadata are only realised when the economic benefits of accessing others' metadata rich products outweigh the overhead of maintaining the provenance of your own product metadata.

Q5: Do you anticipate that any changes will be needed to the both address data and the wider address ecosystem, to support emerging technologies? Please provide evidence of value to support any proposed changes.

We expect other organisations to provide much more detailed contributions on this topic but provide the following considerations.

Access to Address Databases of the highest available precision and accuracy (i.e. via Royal Mail, OS) is incredibly challenging. Improving access to these, particularly with regular and complete updates and refined cost-models, would greatly improve location-based services and associated user-drive applications. It would also enable satellite and Earth Observation products to deliver more focussed and greater value in sectors (i.e. insurance) where precise geo-coding is an essential level of product granularity.

Q6: How should the commission be looking to develop the UK's capability in Earth observation data, both technologically and to support an effective market?

The Commission should look to champion development of the UK's Earth Observation capability with a focus on user-driven <u>exploitation</u> of Earth Observation data *rather than generation of the data itself.*

The Commission should, however, remain well informed on relevant upstream technological developments and associated programmes, including: UK Launch, high-altitude pseudo satellites (HAPs), UK's in orbit demonstration (IOD) programme, and European Programmes such as European Space Agency's (ESA) In-Cubed programme.

Our response addresses opportunities for the Commission to support development of UK Earth Observation capability specifically within the public sector and then the wider public-private sector.

Specific to the public-sector

There is an immediate need for the Commission to play a coordinating role on behalf of the public-sector to accelerate the realising of benefits from exploiting Earth Observation capabilities across government. This coordinating role should focus on four key areas.

- **Centralised procurement of Earth Observation datasets**. There is a severe lack of coordination in the procurement of Earth Observation datasets, whether archive or tasking of satellite imagery, aerial and drone image or LiDAR acquisition. OPEX savings would be made from optimisation of data acquisition strategies and associated services. Most notably however would be immediate CAPEX savings made from:
    - Preventing duplicative data purchase.
    - Receiving significant discount due to data volume requirements.
    - Greater competition from data providers.
- **Effective dissemination of procured Earth Observation datasets**. Datasets procured for one government department must be readily accessible by all government departments. Centralised procurement would ensure data licensing is fit for purpose.
- **Transparency in Product requirements, not Department requirements**. Requirements for either data or services procurement should be collated at the Product level as opposed to stakeholder level with transparency in the services with which they are associated. This allows Data or Service providers to be realistic in their ability to

meet requirements. It is enabled by coordinated data procurement shifting government's position to a fully informed, empowered stakeholder.

- **Re-evaluation of Government's role as a Customer of Earth Observation services.** The Commission is positioned to coordinate a transitioning of the public-sector's role from being thought of as a customer of Earth Observation data and service providers, to playing an integral role within the Earth Observation value added services market. Government would consequentially enable, and financially benefit itself from, market growth. We evidence this further in Q14 for the overall geospatial sector.

Numerous government-led programmes have started to explore the benefits in exploiting Earth Observation capabilities across government. For example, UKSA's Space for Smarter Government (SSGP) Programme, Defra's Earth Observation Demonstration and Integration Pilot (EODIP) initiative, and the Cross-Whitehall Earth Observation Working Group.

Satellite Applications Catapult has been involved across these initiatives and while largely successful, a compelling case can be made for these not having gone far enough. We recommend that **government should move beyond ad-hoc isolated demonstrators and pilots**. Emphasis should be placed on long-term investments into initiatives that do not consider Earth Observation capabilities independently but as an integral component to operational service delivery.

Across public-private sectors

The fragmented and rapidly evolving UK landscape requires clear direction and focus. Clearer rules for engagement and decision-making responsibilities should be defined across the complex stakeholder landscape.

A definite role for the Commission is to help coordinate and champion into government industry-led initiatives that enable UK to take the necessary steps to overcome barriers to exploiting Earth Observation capabilities.

Initiatives such as Satellite Applications Catapult's SEDAS and Data Discovery Hub portals and CEMS cloud computing infrastructure, as well as the Centre for Environmental Data Archive (CEDA), have taken clear steps in the right direction. While funding for these initiatives has been insufficient to realise their full impact, they irrefutably demonstrated the need for and value in single-point discovery and access to geospatial datasets. These Earth Observation assets **provide a foundation upon which the UK could progress toward centralised discovery and access to a distributed geospatial marketplace**. The Satellite Applications Catapult is ideally placed to build on this for the benefit of the whole community and the current and future users.

The industry-led Industrial Strategy Challenge Fund (ISCF) 'Space Data Revolution' Challenge exemplifies the type of ambitious programme required to revolutionise the existing Earth Observation, and wider geospatial, marketplace in the UK.

All these initiatives, even as ambitious as the ISCF, must be supported by efforts to facilitate adoption of specific solutions to challenges in exploiting Earth Observation. This requires a coordinated approach to presenting options for UK government to invest in realising benefits from concepts such as Analysis Ready Data (ARD) and potential national Data and Information Access Services (DIAS). Satellite Applications Catapult should be a key stakeholder in undertaking such a coordinated approach.

Q7. Which new technologies should the commission focus on to provide new opportunities to process and exploit geospatial data for economic growth?

Before the Commission considers any new technologies it's imperative that the systematic data access challenges across the public-sector are appropriately addressed. Unless geospatial datasets are readily accessible by end users and application developers it is not possible to realise the benefits of exploiting geospatial datasets using modern technologies.

Relevant technologies we anticipate impacting upon the geospatial sector over the next 0-5 years may be strategically broken into four categories: **user-led** data generation, information extraction, communication fabric and information dissemination.

Recognising the Commission is unable to remain at the forefront of developments across all the details of these, we raise four priority areas that should be championed:

- **Coordinating strategic Earth Observation concepts and initiatives** within the UK This is a recognised example where there is an urgent requirement for coordination across public and private sectors on strategic developments.
- **Demonstrating adoption of protocols and standards that enable distributed API access to geospatial datasets** across public and private sectors, is another objective the Commission is uniquely positioned to address through investment and policy intervention.
- **Advocating for geospatial within Artificial Intelligence-driven applications.** While significant topics such as ethical AI and explainable AI are being spearheaded into government by organisations such as the Alan Turing Institute and Government Office for AI. Championing, alongside organisations such as Satellite Applications Catapult, the importance of geospatial within these policy conversations is a role the Commission should fulfil.
- **Overcoming blockers to exploiting Artificial Intelligence within geospatial applications**. The Commission is well placed to champion into government existing and new efforts across the UK to overcome key blockers such as scarcity of labelled datasets and significant skills shortages. Example existing initiatives include AI4Space within Satellite Applications Catapult, Ordnance Survey's piloting of deep learning techniques for feature extraction, the Rural Payment Agency's exploration of machine learning for updating the land parcel information system (LPIS) and Office for National Statistics (ONS) Data Science Campus.

We envisage the Commission championing, but not being the lead protagonist in, these and other strategic initiatives that require significant coordination across the UK to deliver maximum social, environmental and economic impact.

The underlying technologies (some of which we identify below) are well considered across the Research Councils and Innovate UK, and organisations such as Satellite Applications Catapult are best placed to help UK capitalise for all future innovations and geospatial market demands.

User-led Data Generation

New datasets driving big data challenges (volume, velocity, value, variability, veracity, and verity of data) will drive new processing and exploitation opportunities.

- The proliferation of IoT devices
    - Energy harvesting low-power sensors (ultra-small and high performance), embedded sensor systems, meta-materials
- Space-based deployable structures
    - Greater technical specification (higher spatial and spectral resolution)
- Quantum Technologies

    - Atomic clocks for more accurate positioning
    - Sensing instruments, magnetometers and gravitometers for providing subtle changes
- New platforms and constellations (and **required policy changes**)
    - Video from space
    - Large satellite and unmanned aerial vehicles (UAVs) constellations providing near-real time (NRT) datasets
    - The emergence of high altitude pseudo-satellites (HAPs) (Zephyr etc.)

Information Extraction

The democratisation of analytics and the empowerment of a digitalised ecosystem. We are in a boom of analytical innovation, however in 10-20 years' time this will be a commoditisation that will imbedded into every device, car, robot, platform, data centre etc. Providing opportunities on these technologies on the coming years will be key to fuelling the geospatial industry.

New Processing Architectures

- Neuromorphic processing mimicking the function of the brain for real time patterns of life recognition
- Quantum computing providing a step change in multiple-iteration computing for generating new analytics models.
- Greater uptake and virtualisation of GPUs
- The intelligent use of CPUs, referal to only using CPUs for functions they excel at

Automation

- Automation has become mainstream, removing and empowering the human in the loop allowing 24hr supply chain changes and scaleable services through the automation of analytics (including, but not limited to, AI).
- Automated data ingestion, control data quality

Artificial Intelligence

- Deep learning neural nets (CNNS, RNNS, self-organising networks, GANs, unsupervised networks, etc.) leading to PaaS
- Semantics: search functionality, qualitative interpretation, data management
- AI algorithmic assurance monitoring, for trust in the models

Data Management

- Scaleable and adaptable infrastructures
- Lossless data compression
- Digital twins, will move from the individual assets to entire ecosystems, country wide digital twin systems.

Security fabrics

- Distributed ledger technology tracking metadata through a system (provenance of data)
- Higher levels of encryption (both on databases and small packets of data)
- Utilisation of quantum key distribution both in space and in terrestrial fibres (quantum entanglement and single photon sources)

Communication Fabrics

5G

- Ensuring the geospatial industry is prepared for next generation terrestrial networks providing greater levels of connectivity and security.
- Understanding the impact of high data volumes and lower latency of information exchange to the users

IoT Networks

- The maturation of IoT networks will provide a big steps forwards in NRT data collection, with networks like LoRawan, Zigbee, SIGFOX etc.

HTS and LEO Constellations

- High throughput satellites and low latency LEO comms satellites combined unrivalled geographical reach with “terrestrial-like” service quality

Information Dissemination

Web and Mobile Platforms

- The use of web and mobile platforms for the dissemination of geospatial services, products and data will continue to increase. It is likely that in the next 24months this will provide the largest exploitation route.
- Maturation of standards, licensing, access and update of open source software components
- Active user communities sharing innovation, accelerating the next evolution of technology

Augment and mix reality Visualisations

- As augment and mix reality visualisation hardware becomes more streamlined and less computer hardware intensive this technology will become more wide spread and a key method of data dissemination for in-field updates of geospatial data

Volumetric Displays

- Currently at a very early stage but has the promise to create a more social way of interacting with digital ecosystems.

Information as Information

- New visualisation technologies are great and have a place, but the geospatial industry will need to get better at just providing information in my circumstances, so integrating with additional client and customer information dissemination systems.

Q8. How can geospatial data and applications be used to support enhanced roll-out of future technologies?

The Commission will provide a bridge into public-sector user requirements, creating demand and setting the foundations for adoption of future technologies.

The intrinsic relevance, ubiquity, volume and variety of geospatial datasets drives the accelerated roll-out of all future technologies.

This trend has already been observed in the AI and Cloud industries. With leading computer vision experts relishing the challenge of unstructured, multi-dimensional and temporal datasets to create more complex and deeper models, and single satellite archives reaching the multi-petabyte size further fuelling the cloud revolution.

UK’s leading position in geospatial should uniquely place government, industry and academia in further addressing important global challenges such as geo-diversity in the adoption of AI-driven applications.

It is now important to look to the future and understand which technologies the geospatial industry will be using in 5 years, to ensure necessary connections are made today to keep the UK at the forefront of the market. These will include:

- Data compression
- Wide area low bandwidth IoT networks
- Large data volume (large data volume, both as a single data point and as a collective dataset) for data provenance and tracking through the supply chain
- Driving AI assurance (tracking of morphing AI models and training dataset bias)

UK cannot realise benefits from geospatial data and applications underpinning the roll-out of future technologies if geospatial datasets are insufficiently accessible.

Q9: What are the options for how public sector organisations could continue to invest in maintaining and enhancing our geospatial data assets?

Whichever option the public-sector pursues for investing in its geospatial assets the Commission must ensure that investments are user-driven, evidence based and sufficiently long-term.

There are far too many options to discuss in any detail here so we have captured key considerations the Commission should make when deciding how best to coordinate future public-sector investments in geospatial data assets.

Continued investments via any option should:

- be **strategically** coordinated.
    - Investment cannot be ad-hoc and must be coordinated by a central body across the sector with a long-term outlook.
- allow a **devolved** approach to managing geospatial data assets.
    - Adoption of standards and best practise must be realistic and implementable with minimal overhead by relevant public-sector stakeholders.
    - De-centralised management of geospatial data and databases is essential, while enabling centralised API access.
- be **modular** and appropriately scoped.
    - Modularity provides opportunity for public-private sector partnerships and agile procurement.
    - Allows distributed, iterative development that can be scaled via Fast Followers across public and private sector.
    - De-risks investments.
    - Enables agile technology adoption.
- be **transparent** across both the public and private-sector.
    - Allows for targeting and cost-effective consulting of industry.
    - Effective propagation of lessons learnt.
    - Provides clarity over responsibilities for maintenance.
- be **evidence-based**.
    - Commission must invest in practically demonstrating the policies it wishes to intervene.
    - Evidence should be gathered within operational delivery environments, not isolated ad-hoc proof of concepts or generation of reports.

Commission-led investment should not be risk adverse. Investments led by the Commission should consciously explore opportunities considered too risky for individual public-sector stakeholders to undertake. Aligning these investments with those of public-private sector funding bodies mitigates risk absorbed by the Commission on behalf of the public sector.

Commitment of the Commission's own budget should strategically align with other funding mechanisms.

The Satellite Applications Catapult looks forward to continuing discussions with the Commission on details of the many options for public-sector investment into geospatial data assets**,** including other funding mechanisms with which it could coordinate.

Q10: What areas of the underpinning geospatial infrastructure such as positioning technologies, including GPS and indoor positioning systems, and geodetic networks and frameworks to support them, should we be prioritising the development of, in order to support the emerging requirements for geospatial data?

Geospatial data alone does not have any requirements.

We expect the Commission to have a far more strategic focus than upon individual components of UK infrastructure. Nevertheless, we make some considerations of components we believe have strategic importance.

- **5G**: Ensuring the geospatial sector has in place the underlying infrastructure required for next generation terrestrial networks providing greater levels of connectivity and security.
- **Internet of Things (IoT)**: Ensuring data access protocols are suited for capitalising on the exploitation of near-real time data streams provided by ubiquitous sensing.
- **High throughput satellites (HTS) and low earth orbit (LEO) constellations**: these data sources combined with low latency LEO communications satellites shall provide unrivalled geographical reach with terrestrial-like service quality.
- **Analysis Ready Data (ARD)**: the unprecedented abundance of geospatial data raises significant questions such as whose infrastructure will be used to store and generate usable geospatial products that don't require an expert to integrate into value-add services.
- **GPS**: It goes without saying that UK must retain its expertise and leading position in the design, development and manufacture of this integral geospatial infrastructure. However, we believe the Commission should focus on downstream exploitation of this infrastructure as opposed to being distracted by the political battles currently afoot.

Both the public and private-sector should be more concerned about leading in delivering sustainable, user-driven value-added services from ANY source of location-based information.

Satellite Applications Catapult is a recognised protagonist across these areas and looks forward to engaging with the Commission as appropriate.

Q11: What role should the private sector have in both the development and maintenance of the underpinning infrastructure and enhancing the UK's geospatial data assets?

The private sector has and should continue to have a major role in the development and maintenance of the underpinning UK geospatial infrastructure.

Whilst there are specialist skills that are required to undertake this task when geospatial data is involved, the systems and software layers that are required are known to industry already, and in many cases are already deployed. They may not currently however be tailored to the public sector's specific needs or be scaled to the required size, so the recommended solution would be for the public sector to place service contract(s) to industry that clearly specify the service requirements and the conditions under which a service contract would be placed (e.g. ongoing performance requirements including penalties, access requirements, data sets, interface requirements, the need for flexibility for system evolution etc), and industry can respond accordingly with appropriate solutions.

The challenge to date has been the lack of coordination in bringing together the various public sector operational requirements to establish an overall procurement such as this. **The Geospatial Commission could be the ideal organisation to consolidate these user needs and to**

centralise service procurement. Special exemption to this approach might be required for users with national security requirements, however even those could potentially be met using industrial providers.

Issues such as vendor lock-in could be avoided via the specification of a modular system using open interfaces and this should form part of the service requirements.

The academic community is perhaps the exception to this, where service level requirements will be different, and IT researchers could support thematic based research users.

Enhancement of UK geospatial datasets is a more complex issue.

Well-established and routine data products could also be delivered by industry, however in many cases the use of geospatial data is highly bespoke and sometimes only needs to be created once to answer a specific question, and where the best knowledge of the problem is contained within the government department itself and not industry.

Outside of having appropriate access to geospatial datasets. It's important that the users (public sector, academics or industry) has access to simple and effective toolsets built on the underpinning infrastructure to allow the rapid fusion of fundamental datasets so that the users can create the outputs themselves. The definition of toolsets and the flexibility to include more in the future could be built into the service requirement for the underpinning infrastructure.

Q12. Do you face challenges when working with geospatial data from across the public sector? If so, what are they and how could value be better released? Are there any technical remedies or standards that could be adopted to improve the interoperability of geospatial data? Please provide supporting evidence of what these remedies could help to accomplish.

Significant public and private-sector value would be realised if geospatial data across the public-sector were made readily accessible. The Commission should coordinate a public-sector transition from being a reluctant customer within the UK geospatial sector to an active participant in the flourishing UK geospatial market.

Our response to Q4 clearly articulated the shared challenges to accessing public-sector datasets:

- Duplicative and disparate sources for individual datasets
- Lack of 'discoverability'
- Spatial and temporal inconsistencies
- Limited or entirely absent metadata
- Inefficient file formatting

We can reinforce our characterisation of the required solution from a user-perspective:

- Centralised Data Discovery
- Enhanced Search Capabilities
- Application Programming Interface (API) Access
- Real Time Updating and Live Streams
- Costing Models (i.e. Revenue Share, Pay-per-Use)
- Traceability and Provenance

As well as our breakdown of how value would be realised within the enabled distributed, agile, evolving marketplace, for example:

- **Reduced service development costs** (software engineering) associated with gaining data access from multiple access portals and API formats

- **Reduced maintenance costs** associated with hosting duplicative data access portal services
- **Reduced storage costs** associated with uncoordinated duplicative datasets
- **Improvement of existing value-added service**s (public and private sector)
- **Creation of novel value-added services** (public and private sector)

Previous attempts to address the underlying interoperability challenges have not been successful. These have encouraged adoption of strict INSPIRE and OGC standards. Investment in these initiatives has been uncoordinated and insufficient to ensure consistent implementation.

An opportunity exists for the Commission to coordinate investment that focuses on user-driven impact that can be evidenced through demonstrating the value of contemporary data access protocols.

If the value in adopting basic (and versatile) best practices is demonstrated with an operational service focus, then benefits can be conveyed in a much more evidence-driven manner across the public sector. Scaling adoption can then be via Fast Followers of the initial pilots.

Not realising this opportunity is a blocker to the UK (both public and private sector) unlocking the real potential value of its existing geospatial assets. It also prevents the UK benefiting from cost-saving and economic growth opportunities associated with agile adoption of the latest and emerging technologies.

Satellite Applications Catapult has a proven record in engaging with public and private-sector organisations with a focus on delivering sustained user and market-focussed impact. We look forward to discussing further ideas of where these opportunities lie with Commission.

Q13. How can the Geospatial Commission act as a more effective customer for geospatial data on behalf of the public sector?

The Commission should be the leading protagonist in coordinating a public-sector transition from a reactive customer of geospatial data and services to assuming an integral and active role in shaping and benefiting from the rapidly growing user-centric UK geospatial market.

We evidence the case for the Commission coordinating such a transition in Q12.

Some important characteristics of the required public-sector investment are reinforced within Q9.

Similar considerations but specific to coordinating public-sector procurement of Earth Observation data and capabilities are detailed in Q6.

Key recommendations for coordination of public-sector procurement of geospatial data and services include:

- **Centralised procurement of geospatial data and services.**
    - Empowers government as a customer.
    - Prevents **duplicative purchase** of data and services.
    - **Significant discount** can be expected due to volume requirements.
    - Greater **competition** from data providers leading to lower costs.
- **Collation of requirements at Product-level, not Department-level**.
    - Allows all **application-specific dependencies** and considerations to be appropriately captured.
    - On a per-product procurement basis this allows Data or Service providers to be **more realistic** in their ability to meet requirements.
    - Undertaken at scale, enables the public sector to **optimise its strategy** to data and service procurement.

- Enables a **modular** and agile procurement approach.
- Focuses on **operational requirements** of public-sector not on ad-hoc project requirements

- **Re-evaluation of public-sector's role as a Customer of geospatial data and services.**
  - Public-sector geospatial datasets should be appropriately integrated into a public-private sector marketplace.
  - This allows local authorities (for example) to capitalise upon their existing and future geospatial assets.
  - It allows government to influence and benefit from the significant market growth being experienced by the geospatial sector.

The Commission should consult existing funding bodies and organisations with considerable experience bridging the gap between the public and private geospatial sectors. For example, leveraging existing networks of Innovate UK, Satellite Applications Catapult and Partner Organisations.

Q14. Are there any additional geospatial datasets, from the other partner bodies or other sources, that the public sector would derive significant benefit from having access to, that might have novel and valuable use cases? What would that access look like?

The Commission should coordinate public-sector investment and initiatives that move toward single-point access for ALL public-sector geospatial datasets by ANY appropriate public-sector stakeholders.

It is unacceptable for geospatial datasets to not be readily accessible by all relevant stakeholders as and when required. The novel and valuable user cases that could be enabled by addressing this challenge too numerous to capture in our response, but we look forward to exploring these in future discussions with the Commission.

Public-sector commercial Earth Observation datasets represent a high-profile user case.

For example, Scaling Rural Payment Agency's Control with Remote Sensing (CwRS) through improved (fully discoverable) access to all public-sector aerial imagery and commercial satellite imagery alongside public sector mapping data which is often derived from the above.

Example geospatial datasets that would contribute substantial economic benefits through being opened to, at least, all relevant public-sector stakeholders include:

- Copernicus and Landsat Earth Observation Analysis Ready Data (ARD)
- Consolidated public-sector commercial satellite datasets
- Consolidated public-sector aerial imagery and LiDAR datasets
- Met Office climate records.
- BGS Geological Map products
- Rural Payment Agency (RPA)'s Land Parcel Information System (LPIS) dataset
- Broadband and comms service datasets
- Address Databases
- Local Authority-unique datasets
- Emergency services various datasets
- Highways England various datasets

As we have stated in other responses (Q4, Q12) this data access should have the following characteristics:

- Centralised Data Discovery
- Enhanced Search Capabilities

- Application Programming Interface (API) Access
- Real Time Updating and Live Streams
- Costing Models (i.e. Revenue Share, Pay-per-Use)
- Traceability and Provenance

An invaluable benefit in addressing this challenge is the ability for the public-sector to evidence and rapidly evaluate potential service improvements. Ready access to products and underlying datasets would enable cost-effective spin-up of sand pit environments within which to conduct collaborative public-private sector R&D.

Accelerating and getting these developments right is hugely pertinent as the public-sector moves toward responsibly realising the benefits from exploiting modern technologies such as Artificial Intelligence. It also allows the public sector to become an intrinsic contributor and benefactor to UK geospatial market growth.

Q15: How can we best develop a single UK strategy, ensuring alignment between the individual strategies across the UK while still allwoing for regional variations?

Playing a coordinating role across the disparate UK geospatial strategies should be a priority for the Commission. The focus for this should be placed on providing top-down context across the various UK organisation strategies.

The Commission should work closely with UK organisations that are well placed across the public and private sector to robustly inform the Commission's own UK geospatial strategy.

This bottom-up approach is crucial to ensure that a UK geospatial strategy is sufficiently representative of all the leading work being undertaken in both public, academic and commercial domains.

Once the Commission has sufficient confidence in its own strategy we expect its Commissioners to play an active role in ensuring appropriate channels of communication exist to:

1. Maintain relevancy and representativeness of Commission's UK geospatial strategy
2. Contextualise regional or organisational strategy variations across the public and private-sector

The space sector is a recognised and leading example within government of effectively engaging across the entire UK landscape.

Satellite Applications Catapult's Regional Centres of Excellence underpin the ability for Innovate UK and Satellite Applications Catapult to recognise regional strengths and weaknesses and therefore drive opportunities for innovation and investment across the entire UK. Other organisations, such as the Knowledge Transfer Networks (KTNs) and the Geovation Hub, should also be relied upon to represent their own extensive networks.

Satellite Applications Catapult's approved 5-year business plan focusses heavily on realising the benefits of Satellite Applications within Geospatial Intelligence. There is clear opportunity to utilise the existing mandate of the Regional Centres of Excellence to support coordination of a UK Geospatial strategy.

Satellite Applications Catapult is ideally placed to support the Commission in developing its strategy. It is also already positioned as a neutral and trusted entity across the public and private-sector so could readily extend its mandate to helping the Commission act upon its strategy.

It is imperative that the Commission works with organisations at the intersection of the public-private sectors to appropriately tie the UK's strategy to **tangible components** that cut across the whole geospatial sector. This cannot be through opening individual datasets one by one or focussing on single organisations one at a time.

The practical components of a UK strategy are discussed at a high-level throughout our response

and should focus on overcoming the key blockers to public and private-sector growth.

Practical components of an overall UK strategy MUST be sufficiently funded with a long-term outlook.

Q16: How can we best ensure effective local authority coordination and sharing of best practise, using location data to better deliver public services?

The Commission should <u>invest</u> strategically to prove the value in adopting best practices across the entire public sector.

Local authorities face the greatest challenge to the consistent adoption of best practices in the public-sector. They also offer the greatest opportunity for realising the full value of public-sector geospatial datasets.

We recommend the Commission consider **two priorities** for addressing this challenge:

- Do not focus on sharing all best practise across all authorities. Focus efforts on one or two service-driven user cases that demonstrate value of contemporary data access protocols and rely upon Fast Followers (and below) to lead to the adoption of the underlying best practices. Adoption would therefore be evidence driven as opposed to policy driven.
- Use Commission funds to regularly convene and support local authority GIS teams and expand the Government Geography Profession to include local authority teams

Q17: As a result of this analysis, we are prioritising the exploration of possible initiatives in the high-value categories identified:

- **property and land**
- **infrastructure and construction**
- **mobility**
- **natural resources**
- **sales and marketing**

What are the existing or potential geospatial applications which could be scaled-up or developed in order to capture economic value? (We would particularly welcome responses from industry and other bodies engaged in these sectors.)

We agree with applications included within the call for evidence and suggest the Commission properly engages key organisations sitting across the public and private sector to expand upon the identified priority areas.

We do, however, expect the Commission not to focus on individual markets or geospatial applications but on user-driven impact that can be evidenced through demonstrating the value of contemporary data access protocols.

As stated in Q4, the Commission can then address the much more pertinent question of which public-sector user-driven applications require **<u>minimal investment</u>** to evidence the necessary value to support policy intervention.

As a technology innovation company that is focussed on driving economic growth in the UK, Satellite Applications Catapult is actively collaborating with a wide range of UK and international stakeholders

across all of these markets and associated geospatial applications.

This uniquely places Satellite Applications Catapult to support the Commission in identifying these opportunities and we look forward to having an ongoing conversation around this topic.

Q18: Are there any other areas that we should look at as a priority?

We trust our response to Q17 sufficiently addresses this question.

Q19: What are the main potential private and public sector innovations that will rely on the use of geospatial data to rollout, and are there corresponding regulatory challenges?

The most significant innovation across the public and private-sector would be creation of a dynamic and transparent user-focussed geospatial marketplace within the UK that bridged across the public and private sector domains.

We outline in Q9 the importance of geospatial in underpinning public and private sector adoption of future technology innovations.

We outline in Q12 the potential sector growth opportunities that could be realised through adoption of best practices across the public sector; these are key innovations!

Further policy intervention is required for the UK to fully capitalise on exploitation of unmanned aerial vehicles (UAV) platforms as sources of geospatial datasets. Associated regulatory discussions must only increase in prevalence as high-altitude pseudo satellites (HAPs) start to play a leading role in the next five years in sourcing geospatial intelligence.

Satellite Applications Catapult is well placed to contribute much greater detail to the insights and examples provided across our response.

Q20: How best can we make the UK's presence in the international geospatial world more visible?

We see significant opportunity in addressing the disparity between the presence that UK government expects to have on the international stage and the necessary investment to substantiate the necessary capability and experience behind that presence.

Three key areas should be considered for improving the UK's international presence in geospatial.

- **Sustained and amplified UK contribution to international committees, agencies and forums**
- **Proving <u>at home in the UK</u> the public-private sector business cases in operationalising geospatial capabilities**
- **A coordinated UK approach to addressing export opportunities**

While acknowledging UK has recognised world-leading expertise in certain areas of geospatial it is well recognised that organisations hosting specialised UK geospatial expertise are extremely poorly funded relative to their international counterparts. Funding for The UK Space Agency (UKSA) is a

good example, when considered against their French and German counterparts National Centre for Space Studies (CNES) and German Aerospace Centre (DLR), respectively.

If the UK expects to be taken seriously on the international stage investment must be considered with equal seriousness.

It is insufficient for individuals engaging on the international stage to expect to be taken seriously. Organisations they represent must be able to demonstrate their relevance within the contemporary international geospatial landscape.

This is challenging for any organisation with the current rate of technological change and the evolving importance of geospatial within this change. It is almost impossible for poorly funded public-sector organisations.

A clear opportunity for the UK lies in demonstrating the business cases in operationalising modern geospatial principles and capabilities. For example scaling Rural Payment Agency's Control with Remote Sensing (CwRS) through improved (fully discoverable) access to all public-sector aerial imagery and commercial satellite imagery.

Without operationalising geospatial capabilities, no public-sector savings are made and consequentially no evidenced story exists for the UK to present to the international community.

If the UK is not willing to invest in these opportunities at home how can it be taken seriously in exporting capabilities abroad?

Continued overseas investment via mechanisms such as the UKSA International Partnership Programme (IPP) is a highly effective means of increasing the UK's international presence. Increased coordination within the UK is required to fully capitalise on export opportunities represented by these international-facing programmes.

There is significant opportunity in using investment such as via UK Overseas Development Aid (ODA) alongside match funding from key international stakeholders such as Australia (i.e. Geoscience Australia, CSIRO) to achieve a common goal; for example tackling issues faced by Pacific Island nations.

Satellite Applications Catapult is uniquely positioned to play a role in the coordination of UK geospatial export. We have a recognised legacy in undertaking this role on behalf of and in collaboration with government and delivering on significant UK export opportunities through our market-facing Value Streams.

A strong differentiator of UK geospatial capability from other nations lies in not just having expertise in geospatial technologies but proven knowledge and understanding of what markets require as a user-driven solution.

Q21: Where should the UK be looking for points of comparison overseas? Who are the other international exemplars? What best practice is being modelled overseas that we can learn from?

Numerous examples exist overseas, many of which are noted in the Commissions call for evidence.

We suggest making a detailed case study of **Northern Ireland's LPS** as an immediate comparator and note the leading ambitions of the **Serbian RGA** and the work they are proposing under World Bank support. Centralised procurement in of the **New Zealand** public-sector is also particularly noteworthy, as is the unique balance between public and private sectors in the **Australian** geospatial landscape.

Satellite Applications Catapult has strong relationships with international organisations leading the way in exploiting geospatial datasets and looks forward to discussing our experiences with the Commission.

Thank you for your time in completing your response to our call for evidence.

Any questions, please get in touch with the Geospatial Commission via geospatialcommission@cabinetoffice.gov.uk

Geospatial Commission: Call For Evidence Response Questionnaire

Please submit your completed questionnaire to:

geospatialcommission@cabinetoffice.gov.uk.

Clearly title your email *'Call for evidence response'*.

About you and your organisation

Name	[Text Redacted]
Organisation	SCISYS UK Ltd
Job title	[Text Redacted]
Address	[Text Redacted]
E-mail	[Text Redacted]
Telephone	[Text Redacted]

Please select which of the following best describes you as a respondent:

Respondent	**Please mark with a X**
Academic	
Business representative / trade body	
Central government	
Charity or social enterprise	
Individual	
Legal representative	
Local government	
Large business (over 250 staff)	**X**
Medium business (50 to 250)	
Small business (10 to 49)	
Micro business (up to 9)	

Other - please state	

Call for evidence - three key themes

We have identified three high-level themes that could help our approach to setting a strategy which are as follows:

1. **Supporting innovation in the geospatial sector**, exploring how to secure cutting edge skills, the right access to data, and opportunities from emerging technologies for the geospatial sector itself
2. **Enhancing the UK's geospatial assets,** looking at how best to align interests, avoid duplication, and instill best practice across the whole public sector
3. **Driving investment and productivity in geospatial applications**, asking in which wider sectors the most value lies from better exploitation and use of geospatial data, in the UK and internationally

Our questions

Q1. Is our view of the geospatial data types accurate? If not, what should be included or excluded from this?

Overall we generally agree with the 4 geospatial data types: geospatial data, positional data, geospatial identifiers, geospatial services.

The following comments have however also been noted :

- Data descriptors and metadata to support interoperability are missing;
- We suggest OGC-compliant tools to help with cataloguing and data federation.

Q2. In addition to current government policy, what are the areas of geospatial skills where the commission could best focus, to help ensure the necessary capability within the UK for the future?

SCISYS comes at the geospatial arena from the perspective as a software development house with a geospatial specialism. Therefore we encourage the commission to think about focussing on technologies that enhance the core geospatial toolkit thus widening its reach. These would include:

- Coding skills, particularly Python and JavaScript
- Database knowledge, including SQL and management scripting
- Experience with cloud infrastructure platforms for managing large datasets

Q3. What are the geospatial skills needs and gaps in your organisations, how can these be most effectively addressed, and how can careers in the sector be best promoted?

For geospatial skills we find that software developers and Geographical Information Systems (GIS) users/experts are potentially easier to resource than those with experience in earth observation skills covering data processing/ management and analytics etc.

In addition, while there are many interested in the more recent technologies i.e. big data analytics, application of machine learning and artificial intelligence to geospatial data, it is more difficult to find a rounded person with complimentary skills to allow for management, project delivery etc. The market to secure these individuals is proving very competitive especially for those with an experience level between new graduates and senior/ very experienced.

Careers in the sector could be promoted through:

- Graduate fairs
- The STEM Ambassador Hubs (Hubs connect teachers, leaders of non-school groups, STEM Ambassadors and employers in order to build and inspire the next generation of STEM professionals).
- Social media
- Industry specific job boards
- Engaging with imagery and geospatial software suppliers to encourage more to host industry days, Special Interest Groups (SIGs), user groups etc.
- The MOD is also a source of users trained in a variety of geospatial skills. By connecting with these groups, their knowledge and expertise could be adopted into other public or private sectors.

Q4. Are there any publicly or privately-held geospatial datasets that are currently challenging to access or use or of insufficient quality, but which you or your organisation would find valuable if these issues could be resolved? Please explain why this would be of value, and how access/quality could be improved?

With regard to publicly held geospatial datasets it is clear that what is required is a wholescale revision of how this data is provided. At the moment there is massive variation in the quality, availability, physical format, cost and licence type in which public data can be consumed. Data.gov.uk is not really fit for purpose and the UK should follow international leaders in this area and set up a dedicated spatial data portal. This should include traditional geospatial data and earth observation data.

The commission should encourage all public data (that do not have a security implications) to be made freely available in OGC compliant formats. There is also a requirement to encourage the appropriate refresh of data especially for more dynamic datasets.

A good recent example of this is the confusing messages around the opening up of MasterMap. For many in industry this was a real opportunity to commit to open data agenda but what was announced was underwhelming and an opportunity missed.

Q5: Do you anticipate that any changes will be needed to the both address data and the wider address ecosystem, to support emerging technologies? Please provide evidence of value to support any proposed changes.

As above address data and standards should be fully open i.e. open data following open standards. Once this is resolved emerging technologies will then be able to innovate.

Q6: How should the commission be looking to develop the UK's capability in Earth observation data, both technologically and to support an effective market?

Currently in the UK there are initiatives/ programmes that have been set up for accessing various Earth Observation data sets however these are rather fragmented or organisations are carrying out similar work (i.e. for Copernicus data access, UKSA have invested access via the SEDAS hub while STFC have invested in the JASMIN facility).

Ideally there would be a joined up approach for access to geospatial and Earth Observation data in the UK. This would include considering the required storage and processing capacity, through to a delivery mechanism of analysis-ready data,

services etc to both government and commercial customers. The commission would be considered an appropriate body to coordinate the geospatial data requirements from UK government customers and also additional programmes including the UK Space Sector Deal, and the ISCF Wave 3 “Space Data Revolution” challenge proposal.

There is also the concern of the impact that Brexit will have on contracts with the EU Copernicus Programme for both current and future work to be undertaken as there is much opportunity here. In particular, there is the opportunity to input in the future direction of the programme which could benefit the UKs earth observation data requirements. Support from the commission to organisations such as the UKSA that are working on keeping the UK in such programmes post Brexit, would be encouraged.

Q7. Which new technologies should the commission focus on to provide new opportunities to process and exploit geospatial data for economic growth?

There are several technology areas which can be focused on to provide new opportunities

- Integration of new technologies. For example, artificial intelligence, machine learning, big data analytics etc which are already improving how geospatial data can be processed and analysed etc
- Delivery of services/ products. This is continually evolving with increasing advances and improvements in technology and so should reflected on how services/ products can be offered to consumers
- UK Technology Industry. UK industry and research is experienced in developing technologies such as smallsat constellations, satellite video constellations through to involvement in horizontal spaceport development across Britain. This is linked to creation of data and so investing in this area needs to continue.

Q8. How can geospatial data and applications be used to support enhanced roll-out of future technologies?

It seems slightly odd that the focus here is on the roll out of future technologies. Surely the focus should be on the roll out of future services that are delivered by future technologies and enabled by geospatial data and applications?

We would suggest by working in partnership public and private organisations will find appropriate scenarios where geospatial data and applications can support the rollout of future technology enabled services.

To support this we would echo earlier thoughts about the need for the public sector to truly open up data holdings to enable innovation.

Q9: What are the options for how public sector organisations could continue to invest in maintaining and enhancing our geospatial data assets?

Given current budget constraints and political focus it is evident that what is required is a sustainable approach for public sector organisations.

With this in mind we would suggest that organisations collect and maintain geospatial data that supports their core public purpose and their own operational requirements. As described above this data should then be made freely available using the OGL and OGC standards via a single UK geospatial data portal rather than the current plethora of portals.

Q10: What areas of the underpinning geospatial infrastructure such as positioning technologies, including GPS and indoor positioning systems, and geodetic networks and frameworks to support them, should we be prioritising the development of, in order to support the emerging requirements for geospatial data?

Increasingly, end-users and developers of connected devices expect location-based services to be ubiquitous, but they are challenging to deliver in certain environments (such as deep underground or in areas where wireless transmissions are prohibited). Enhancing the capabilities of geo-positional handoff between traditional technologies such as GNSS and more niche approaches such as photogrammetric navigation-from video and inertial or barometric sensors will allow users to interact with digital content more seamlessly. Examples would be surveyors gaining an interactive understanding of underground utility networks using unmanned, location-aware robotics or users experiencing augmented reality (AR) guides to underground metro systems etc.

Q11: What role should the private sector have in both the development and maintenance of the underpinning infrastructure and enhancing the UK's geospatial data assets?

We would be in favour of the private sector supplying the development and maintenance of the underpinning infrastructure to the UK's geospatial data assets providing that it is made equally accessible to all UK stakeholders and that it was cost effective.

Q12. Do you face challenges when working with geospatial data from across the public sector? If so, what are they and how could value be better released? Are there any technical remedies or standards that could be adopted to improve the interoperability of geospatial data? Please provide supporting evidence of what these remedies could help to accomplish.

Challenges include everything from the quality, availability, physical format, cost and licence type in which public data can be consumed.

Government should publish all data under the OGL and make it available using OGC compliant methods ideally via one UK spatial data portal.

Other than obvious budget issues the only barrier to this position would appear to be organisations own vested interests in the data and the confusing semi-commercial position that some public sector bodies have adopted which is often at odds with their public purpose.

Q13. How can the Geospatial Commission act as a more effective customer for geospatial data on behalf of the public sector?

If this question means in terms of the public sector buying commercial data for the public sector as a whole then there are obvious economic benefits of doing this in bulk.

Q14. Are there any additional geospatial datasets, from the other partner bodies or other sources, that the public sector would derive significant benefit from having access to, that might have novel and valuable use cases? What would that access look like?

There are various data sets that would be useful if they could be accessed and exploited however it is often either commercially sensitive or privacy issues that complicate the matter. For example, traffic data feeds, crime statistics, social media, insurance claims etc. but also access to affordable high resolution, frequently updated satellite/ aerial imagery.

Q15: How can we best develop a single UK strategy, ensuring alignment between the individual strategies across the UK while still allwoing for regional variations?

It would seem that there are two main aspects for this

- You will need to square the circle of whether the approach is bottom up or top down. Given the move to regionalisation we would suggest that to get the buy-in from regions there needs to be a significant element of bottom up
- Basing the strategy on open standards will encourage interoperability between the regions

Q16: How can we best ensure effective local authority coordination and sharing of best practise, using location data to better deliver public services?

Engagement and coordination with the Local Government Association (LGA) could provide most effective, see https://www.local.gov.uk/our-support/guidance-and-resources/data-and-transparency/geographic-information/geospatial

Q17: As a result of this analysis, we are prioritising the exploration of possible initiatives in the high-value categories identified:

- **property and land**
- **infrastructure and construction**
- **mobility**
- **natural resources**
- **sales and marketing**

What are the existing or potential geospatial applications which could be scaled-up or developed in order to capture economic value? (We would particularly welcome responses from industry and other bodies engaged in these sectors.)

While the categories identified are rather broad in scope they are mostly well established in using geospatial data of one variety or another. Applications could be scaled up when combined with additional data sets or with new techniques such as machine learning or artificial intelligence. For example in the utilities sector, tunnels require regular inspections which are carried out by engineers and can be time consuming and pose significant risks. Robotic survey together with deep learning tools can now be used in tunnel inspection to automatically find, label and analyse features/defects in survey imagery. Combined with other geospatial data i.e. radar for subsidence detection, a greater picture can be provided regarding how the surrounding environment can affect tunnels.

Q18: Are there any other areas that we should look at as a priority?

With the continuing increase of earth observation data capture ie, drones, high altitude platforms, higher frequency satellite revisits and improving resolution, we would like the commission to encourage their development and uptake. Combined with additional geospatial data and processing or analytical technologies such as artificial intelligence and machine learning, there are continual applications and services being developed that can be utilised in the public and private sectors and potentially for export.

Q19: What are the main potential private and public sector innovations that will rely on the use of geospatial data to rollout, and are there corresponding regulatory challenges?

Services or products whose inputs/outputs include, or are derived from, location information would be seen as potential private and public sector innovations that rely on the use of geospatial data – example sectors could include smart cities, climate and energy, critical infrastructure monitoring, insurance, health etc.

Potential corresponding regulatory challenges could include :

- The General Data Protection Regulation (GDPR) regulation in EU law on data protection and privacy for all individuals, i.e. some attribute in geospatial data could hold personal data
- How geospatial data is collected from various sources i.e. drones, autonomous vehicles etc

Q20: How best can we make the UK's presence in the international geospatial world more visible?

In order to increase the UK's visibility in the international market, it needs to develop scalable ideas which include new technologies and data sources but also be a leader in open geospatial data to enable operating in the global geospatial community. The Department of International Trade (DIT) would also be a body to engage with to understand their guidance, export initiatives, experiences etc.

Q21: Where should the UK be looking for points of comparison overseas? Who are the other international exemplars? What best practice is being modelled overseas that we can learn from?

In Europe there are several Copernicus Data and Information Access Services (DIAS) which give unlimited, free and complete access to Copernicus data and information. A DIAS not only provides a cloud-based one-stop shop for all Copernicus satellite data and imagery as well as information from the six Copernicus services, but also gives access to sophisticated processing tools and resources.

In the US they have established a national geospatial "GeoPlatform" which is a platform that provides shared and trusted geospatial data, services, and applications for use by the public and by government agencies and partners. It is a shared infrastructure that can host a user's data and applications and can be seen as a focal point where governmental, academic, private, and public data can be visualised together to inform national and regional issues.

Thank you for your time in completing your response to our call for evidence.

Any questions, please get in touch with the Geospatial Commission via geospatialcommission@cabinetoffice.gov.uk

Geospatial Commission: Call For Evidence Response Questionnaire

Please submit your completed questionnaire to:

geospatialcommission@cabinetoffice.gov.uk.

Clearly title your email *'Call for evidence response'*.

About you and your organisation

Name	[Text Redacted]
Organisation	Scottish Environment Protection Agency (SEPA)
Job title	[Text Redacted]
Address	[Text Redacted]
E-mail	[Text Redacted]
Telephone	[Text Redacted]

Please select which of the following best describes you as a respondent:

Respondent	**Please mark with a X**
Academic	
Business representative / trade body	
Central government	**X**
Charity or social enterprise	
Individual	
Legal representative	
Local government	
Large business (over 250 staff)	
Medium business (50 to 250)	
Small business (10 to 49)	
Micro business (up to 9)	

Other - please state	

Call for evidence - three key themes

We have identified three high-level themes that could help our approach to setting a strategy which are as follows:

1. **Supporting innovation in the geospatial sector**, exploring how to secure cutting edge skills, the right access to data, and opportunities from emerging technologies for the geospatial sector itself
2. **Enhancing the UK's geospatial assets,** looking at how best to align interests, avoid duplication, and instill best practice across the whole public sector
3. **Driving investment and productivity in geospatial applications**, asking in which wider sectors the most value lies from better exploitation and use of geospatial data, in the UK and internationally

Our questions

Q1. Is our view of the geospatial data types accurate? If not, what should be included or excluded from this?

There is a need for clear examples of each type to avoid assumptions, e.g.

1. Geospatial data: raster & vector
2. Positional data: address
3. Geospatial identifiers: TOID; UPRN
4. Geospatial services: Does this include WMS & WFS, or does it refer to applications such as Google Maps?

Q2. In addition to current government policy, what are the areas of geospatial skills where the commission could best focus, to help ensure the necessary capability within the UK for the future?

Spatial analysis skills as part of the school geography curriculum.

Support knowledge transfer fellowships between academia and public & private sector organisations, such as the NERC fellowships.

Establish fellowships specifically for Earth Observation data analysis.

Q3. What are the geospatial skills needs and gaps in your organisations, how can these be most effectively addressed, and how can careers in the sector be best promoted?

There is a need for highly numerate individuals with good analytical skills and an eye for detail. Current gaps include machine learning and the application of artificial intelligence.

Q4. Are there any publicly or privately-held geospatial datasets that are currently challenging to access or use or of insufficient quality, but which you or your organisation would find valuable if these issues could be resolved? Please explain why this would be of value, and how access/quality could be improved?

A significant dataset that is currently difficult to access are the historic aerial photographs held by the National Collection of Aerial Photography (NCAP). The difficulty arises from the fact that in Scotland there are 1.3 million photographs catalogued of which 100,000 have been digitised. Having the rest of the images digitised would allow easier access to the archive which would benefit restoration projects on water courses and reservoirs. The photos allow the location of old river channels to be identified.

Q5: Do you anticipate that any changes will be needed to the both address data and the wider address ecosystem, to support emerging technologies? Please provide evidence of value to support any proposed changes.

Release of UPRN is a good start.

Large number of buildings do not have a unique address when they are part of a large site (eg. hospitals, universities, industrial complexes) if this were carried out it would aid our ability to accurately assess regional flood risks.

Q6: How should the commission be looking to develop the UK's capability in Earth observation data, both technologically and to support an effective market?

Supporting the availability of analysis ready data for the UK public sector through the DEFRA / JNCC project. This will save organisations considerable amounts of processing time and enable greater use of the data to answer questions.

Q7. Which new technologies should the commission focus on to provide new opportunities to process and exploit geospatial data for economic growth?

Cloud computing access for public sector bodies.
Maximising use of EO data through supporting provision of analysis ready data, e.g. via the DEFRA/JNCC platform.
Artificial intelligence and machine learning with EO data.

Q8. How can geospatial data and applications be used to support enhanced roll-out of future technologies?

Vital for use with developing driverless vehicle technology.
Internet Of Things (IOT) sensors and monitoring

Q9: What are the options for how public sector organisations could continue to invest in maintaining and enhancing our geospatial data assets?

Framework agreements such as the One Scotland Mapping Agreement have provided a method for Ordnance Survey to fund ongoing maintenance of detailed topographic data & a gradual improvement of 1:10,000 areas to 1:2,500.
Creation & maintenance of good quality metadata through the enforcement of existing standards.
The public sector generate a considerable amount of geospatial data – increasing its visibility and use will lead to quality improvements as issues are identified and then fixed.

Q10: What areas of the underpinning geospatial infrastructure such as positioning technologies, including GPS and indoor positioning systems, and geodetic networks and frameworks to support them, should we be prioritising the development of, in order to support the emerging requirements for geospatial data?

Continue to support GPS base stations via OS Net.
Using data from monitoring sea level rise to see how this is going to impact the various Ordnance and UKHO datums.

Q11: What role should the private sector have in both the development and maintenance of the underpinning infrastructure and enhancing the UK's geospatial data assets?

Support the likes of NCAP (National Collection of Aerial Photography) in the digitisation of historic aerial photographs for the UK.

The private sector can often work faster and more flexibility and efficiently. In collaboration with the public sector this could potentially allow faster roll out of emerging technologies.

Q12. Do you face challenges when working with geospatial data from across the public sector? If so, what are they and how could value be better released? Are there any technical remedies or standards that could be adopted to improve the interoperability of geospatial data? Please provide supporting evidence of what these remedies could help to accomplish.

Access to local authority contaminated land assessment datasets is very difficult. Local Authorities are reluctant to share this information for fear of property blight. The creation of nationally consistent & open dataset could provide an incentive to cleanup contaminated areas.

In fulfilling our duties under the flood risk management act SEPA creates a large amount of spatial data with the aim of sharing this data with Responsible Authorities and national stakeholders and vice versa. Doing this in reality often takes time and resources and is constrained by the following:

- Licensing conditions
- Physical sharing of data i.e. which platforms to share it on (CD, hard drive, email etc)
- Lack of consistent software across all organisations to view and manipulate data
- Some organisations having a lack of technical staff skills to manipulate or simply view the data

Version control when new data is supplied to responsible authorities which supersedes previous versions

Q13. How can the Geospatial Commission act as a more effective customer for geospatial data on behalf of the public sector?

The GC could act as central point of purchase and realise economies of scale when purchasing widely used datasets. The PSMA / OSMA has worked well and the same model has been extended to other suppliers e.g. BGS. The same model could be extended further e.g. CEH.

Q14. Are there any additional geospatial datasets, from the other partner bodies or other sources, that the public sector would derive significant benefit from having access to, that might have novel and valuable use cases? What would that access look like?

Centre for Ecology and Hydrology datasets such as Land Cover 2015.

Historic aerial imagery for the whole of the UK – from the National Collection of Aerial Photography. Uses for the data include the assessment of contaminated land, geomorphological investigations, historic river channel analysis.

Historic maps – support the National Library of Scotland in providing a WMS of all the OS paper map series.

LiDAR data – until the point of full national coverage, ensuring that as much of the data that has been flown is available as possible.

Q15: How can we best develop a single UK strategy, ensuring alignment between the individual strategies across the UK while still allowing for regional variations?

It's important to reference the strategies developed by the devolved administrations.

Q16: How can we best ensure effective local authority coordination and sharing of best practise, using location data to better deliver public services?

Support initiatives such as the Scottish Government's Improvement Service Spatial Hub (http://www.spatialhub.scot/). The SpatialHub supports Local Authorities to provide spatial datasets which are collated into national datasets & made available as WMS / WFS to OSMA members. Having a single version of the truth at a national level is extremely useful.

Q17: As a result of this analysis, we are prioritising the exploration of possible initiatives in the high-value categories identified:

- **property and land**
- **infrastructure and construction**
- **mobility**
- **natural resources**
- **sales and marketing**

What are the existing or potential geospatial applications which could be scaled-up or developed in order to capture economic value? (We would particularly welcome responses from industry and other bodies engaged in these sectors.)

A fully populated national land register is a starting point.
An open agricultural fields dataset, e.g. derived from the SIACS (Scottish Integrated Administration and Control System) database.
E-planning – roll out an automated process to include the consultation process with statutory consultees.

Q18: Are there any other areas that we should look at as a priority?

Q19: What are the main potential private and public sector innovations that will rely on the use of geospatial data to rollout, and are there corresponding regulatory challenges?

Open access to SIACs data would enable an improvement in the modelling of water quality, which would help to identify those areas where mitigation actions will provide the most benefit in reducing agricultural pollution.

Q20: How best can we make the UK's presence in the international geospatial world more visible?

Carry on with implementation of INSPIRE.

Q21: Where should the UK be looking for points of comparison overseas? Who are the other international exemplars? What best practice is being modelled overseas that we can learn from?

The USA has a long history of open data which is used to support the wider economy.

Australia have launched a 'National Map': https://nationalmap.gov.au/about.html.

Estonia – use of blockchain in geospatial applications.

Geospatial Commission: Call For Evidence Response Questionnaire

Call for evidence - three key themes

We have identified three high-level themes that could help our approach to setting a strategy which are as follows:

1. **Supporting innovation in the geospatial sector**, exploring how to secure cutting edge skills, the right access to data, and opportunities from emerging technologies for the geospatial sector itself
2. **Enhancing the UK's geospatial assets,** looking at how best to align interests, avoid duplication, and instill best practice across the whole public sector
3. **Driving investment and productivity in geospatial applications**, asking in which wider sectors the most value lies from better exploitation and use of geospatial data, in the UK and internationally

Our questions

Q1. Is our view of the geospatial data types accurate? If not, what should be included or excluded from this?

We understand the need to be clear on the terminology used in the development of a shared UK strategy and to help non-geospatial users understand the meaning behind these terms. However, as they stand they are ambiguous and much real data could be categorised under more than one data type – some real world examples would help to clear this ambiguity.

Also, positional data is not a commonly used term by geospatial professionals and perhaps thematic data or geographically referenced data would be a better fit.

Q2. In addition to current government policy, what are the areas of geospatial skills where the commission could best focus, to help ensure the necessary capability within the UK for the future?

Geospatial/GIS or geography skills can no longer be viewed as solely the ability to use a desktop GIS for analysis but much encompass a wide range of skills from cloud based analytics, programming, to geospatial data management. GIS professionals must also learn to working in multidisciplinary teams alongside other ICT professionals. This mirrors the digital fuelled evolution of the wider analytical and data science professions.

The Commission has already announced plans to make more core geospatial data open – Open MasterMap project. One of the main questions leading on from this announcement was how the Commission could support the market in making best use of this data - the availability of individuals with geospatial skills in the commercial world to be able to understand and make use of the data and the knowledge and awareness of business and policy leaders to allow them to identify the opportunities to exploit geospatial data and expertise.

We know that individuals with geospatial skills are increasingly hard to recruit in the public sector and this likely to be mirrored in the commercial world. Within the Scottish Government, we have had to accept that starting salaries mean we either appoint candidates who are underqualified in some areas (developing methodologies for data creation, understand geospatial standards, technically able to script in a range of programming language and geospatial database management and future needs of AI and Machine learning) or choosing to appoint candidates at a more junior level with the intention to develop them in the roles. It is clear that once they are trained up they have developed valuable skills and move on to post at a higher grade in SG or external companies(i.e. renewables companies). It is also important to note that these approaches have significant negative consequences: they reduce the productivity of teams who have to invest more time in developing and coaching staff and they increase pressure on a small cohort of specialists who retain the high order skills necessary to sustain business as usual.

To ensure they longer term capability, there are a few areas of focus:

A) To develop long term capability we need to start at schools – lack of awareness that geospatial is a career choice goes back to them. There are already a number of existing education outreach projects, some of these will have been touched on by other organisations responses but those we are aware of are :

- AGI Scotland - Geospatial Emerging Talent
- AGI - Early Careers Network
- ESRI - ArcGIS Online for Schools
- ESRI - GeoMentoring
- RGS - Ambassador Scheme promoting Geography/GI to schools

B) Within further education there are a number of areas that potentially train students in geospatial skills - MSc in GIS, Data Science, and ICT. Data science is a growing market and to meet this increasing demand a Scottish Government funded Innovation centre - DataLab runs a number of data science placements and secondments - https://www.thedatalab.com/what-we-do/skills-and-training. Whilst experience in Scottish Government has shown there is a still a lack of

geospatial training for data scientists this model developed by DataLab of summer placements/internships for data scientists working with private and public sector orgs is something we should learn from.

C) Improving the levels of geospatial awareness in business / decision makers. Many part of the public sector amass large amounts of geospatial data with little understanding of what to do with it, it sits underutilised and they don't value geospatial skills within their own organisation.

Q3. What are the geospatial skills needs and gaps in your organisations, how can these be most effectively addressed, and how can careers in the sector be best promoted?

Much has been covered in Q2 but the main geospatial skills and gaps in Scottish Government are:

- ICT and business lack understanding of geospatial data
- Legal and Licensing – licensing geospatial data is complex and often a skill in itself
- Earth Observation and remote sensing skills – see response to Q6
- Experience of implementing accessibility standards, data schemas and publishing geospatial data – this includes data management and the creation of metadata.
- Future skills - cloud analytics and machine learning

The commission may have a role in mobilising organisations to address these issues at the organisational level, for example increasing the general understanding of geospatial across managers and ICT professionals but there are two professional development schemes that could be used to promote geospatial careers in the public sector:

- Government Science and Engineering (GSE) – Geography Profession
- Digital, data and technology (DDATS) profession - https://www.gov.uk/government/organisations/digital-data-and-technology-profession

Q4. Are there any publicly or privately-held geospatial datasets that are currently challenging to access or use or of insufficient quality, but which you or your organisation would find valuable if these issues could be resolved? Please explain why this would be of value, and how access/quality could be improved?

Addressing is the area in which there are the greatest number of reported issues and which is of the highest concern to users. Accurate addressing information, a single source of standardised addressing data, was a high priority for many parts of Scottish Government and needs to be resolved. Key areas mentioned: the Emergency Service Gazetteer; the 2021 Census; CHI – NHS health number; Persons at Risk register; Resilience planning; Superfast Broadband Reaching 100% Programme.

Other data with access, licensing or quality issues are:

- Marine (UKHO) data – complex licensing and derived data issues. The experience from Scottish Government is that chart data is available under commercial licence for non-navigational purposes, and only available in GIS ready format (raster/vector) from resellers such as OceanWise. Advice from UKHO IPR team is that derived material can only be used for internal purposes, and can't be released under OGL. For example - harbour limits dataset created by digitising descriptions and coordinates from legislation was provided to UKHO but the data supplied via OceanWise has not been updated. Where the legislation was unavailable for harbour limits, we used those depicted on the chart (as advised by harbour authorities). UKHO refused the request to share this data (for 5 ports) as derived data.
- Data from commercial infrastructure companies such as broadband network data for use in the Superfast Broadband Reaching 100% programme is often seen as commercially sensitive and very difficult to access.

Q5: Do you anticipate that any changes will be needed to the both address data and the wider address ecosystem, to support emerging technologies? Please provide evidence of value to support any proposed changes.

Yes, Scotland (and the UK) does not currently have an addressing product containing all the addresses (or premises) in a simple, consistent and definitive manner. Existing addressing products are vast, complicated datasets which require significant skill to manage and interpret in order to extract relevant information, particularly in order to extract information on records referring to premises which may require delivery of a utility.

For example, in Scotland work undertaken by NRS to identify all relevant records required to conduct the 2021 statutory census is costly and time consuming. They are unable to guarantee the completeness and accuracy of the address register for census due to inconsistencies and flaws in the core data and its maintenance

regimes and the high number of records requiring manual assessment to classify record type.

There is also a lack of consistent advice on how to interpret existing products to identify premises leading individual broadband suppliers, market regulators and government to potentially take different approaches, in turn leading to variation in the model held by each body informing the extent of premises requiring a service.

Finally, the multiple ownership of the data and layering of intellectual property and licensing creates complexity and inhibits access to data. Royal Mail, Local Government (IS in Scotland and Geoplace in England and Wales) and OS and issues of complexities around who has rights to make changes and corrections as well as legacy inconsistency in the naming of addresses (i.e. tenements in Scotland) all need to be resolved.

Q6: How should the commission be looking to develop the UK's capability in Earth observation data, both technologically and to support an effective market?

There are a wide range of potential EO applications in terrestrial and marine environments and Scotland has a strategic interest in making sure this potential is utilised. We want to ensure we are in a position to exploit the freely available outputs from the European Space Agency Earth Observation (EO) Programme (Copernicus), in particular Sentinel 1 (radar) and Sentinel 2 (imagery) satellites as well as other higher resolution satellite data. We have adopted a collaborative approach to EO; central to this is the Scottish Remote Sensing Working Group (RSWG), which includes members from a variety of agencies across the Scottish Public Sector. Members of the team also represent the interests of the RSWG at the wider-UK groups including the Defra Earth Observation Centre of Excellence (EO CoE). From both these groups the main areas of interest are:

A) Platform to allow public sector access to analysis ready data (ARD) and intermediate data (like water or vegetation indices) coming from EU Copernicus satellites and potentially other commercial high resolution satellite. Defra EO CoE has already delivered an Alpha prototype and is ready to go into Beta production phase. We would like to work with Defra, Welsh Government and Northern Ireland to ensure one point of access to all public sector in the UK. The platform should also provide the ability to carry out analysis /machine learning via tools in the cloud.

B) Continued access to Copernicus programme particularly the continued ability to use the Emergency Mapping service – this was recently activated by SNH to help understand and manage wildfires in Scotland.

C) An EO Skills framework is being developed by JNCC as part of the EO CoE and continued support for this work is essential

D) There are also a series of important cross-agency EO projects, with, for example DEFRA, SNH, SEPA and FCS, being coordinated by members of the

RSWG which demonstrate and promote the use of remote sensing data for a wide variety of applications. These include the study of diffuse pollution in Scotland's water environment, monitoring peatland condition, assessing wind damage in forests, mapping trees outside of Scottish woodlands, and creating a Scottish crop map. We would like to see this collaboration to continue but it will need additional resources.

Q7. Which new technologies should the commission focus on to provide new opportunities to process and exploit geospatial data for economic growth?

)ud infrastructure – Cloud platforms are fast becoming the vehicle for geospatial data storage, access and analytics, artificial intelligence, machine learning, predictive analytics, big data, and the Internet of Things. Cloud services can deliver agility, scalability, innovation, and potentially cost savings. However, this brings with it different cost models for cloud versus in-house infrastructure, trust/security issues, new skills and will challenge the traditional GIS desktop analytical methods and processes.

B) Machine learning – Increasingly used as part of EO projects such as crop mapping and assessment of catastrophic wind damage in forestry

C) Blockchain / Distributed Ledger – how we hold health data and how citizens engage with data

D) LiDAR and 3D technologies – Improved height data for modelling and forecasting by the public sector. This impacts commercial sectors e.g. planning / timber /insurance/ flooding

Q8. How can geospatial data and applications be used to support enhanced roll-out of future technologies?

Examples of technologies geospatial can support:

- Blockchain
- Micro satellites
- Integrating AI and automating mapping for on the fly imaging processing
- BIM
- 5G rollout

Q9: What are the options for how public sector organisations could continue to invest in maintaining and enhancing our geospatial data assets?

In Scotland the public sector uses and creates a large amount of geospatial data and it must ensure that it is well placed to maximise the value of that data. The effective maintenance of this data to ensure it is fully exploited, fosters innovation, delivers effective public services and promotes economic growth is an essential. Thoughts on where to invest:

A) Collaboration not duplication - Identify priority collaborative data procurements and data collection/maintenance projects through engagement with public sector organisations and data suppliers. Development of guidelines that help us to understand economic cases and issues like data sharing and archiving. Example projects would be Greenspace and Aerial Photography.

B) Investment in skills – discussed in Q3

C) Communicating the importance of GIS to managers/ decision makers - discussed in Q2

D) Implement and drive adoption of open data standards on interoperability and access – discussed in Q12

Q10: What areas of the underpinning geospatial infrastructure such as positioning technologies, including GPS and indoor positioning systems, and geodetic networks and frameworks to support them, should we be prioritising the development of, in order to support the emerging requirements for geospatial data?

UK ground truthing product – Ground truth datasets exist across a number of public sector organisations, private sector data suppliers and research institutes. Could these be standardised and made accessible to create a UK wide product used to ground truth a range of remotely sensed data (ie Copernicus, LiDAR, aerial photography)?

Q11: What role should the private sector have in both the development and maintenance of the underpinning infrastructure and enhancing the UK's geospatial data assets?

A) Innovation and collaboration – Scottish Governments CivTech programme has already demonstrated how it is possible to engage digital entrepreneurs and small businesses in developing solutions to sometimes intractable problems. Can this model be re-used with a focus on geospatial challenges? Examples of the projects can be found here - https://civtech.atlassian.net/wiki/spaces/CIV/pages/45847042/3.0+challenges

B) Implementation of standards - make their own data more discoverable and share (where commercial sensitivities allow) data – particularly infrastructure providers

C) Quality assurance role - 3rd party quality assurance on public sector data

D) Increase the wider adoption of the UK's geospatial assets – for example the development of Geovation Scotland hub and a tech accelerator / incubator programme or development of a geospatial cluster (through a network integrator) in Scotland drawing upon public and private sector expertise to build partnerships that can address the opportunities and challenges that access to good quality geospatial data enables.

Q12. Do you face challenges when working with geospatial data from across the public sector? If so, what are they and how could value be better released? Are there any technical remedies or standards that could be adopted to improve the interoperability of geospatial data? Please provide supporting evidence of what these remedies could help to accomplish.

A) Discoverability of geospatial data -

- Scotland has its own geospatial discovery portal – www.spatialdata.gov.scot (based on GeoNetwork, also used by Environment Agency) which could potentially be rolled out for UK use. This is the single source of discovery geospatial metadata for the public sector, the site harvests metadata from other repositories and has an API to expose the metadata for use by others. This could mean, for example, organisation, could potentially remove the need to install, maintain and administer their own metadata stores (with guidance).

- Work with the Spatial Data on the Web group (a W3C group) monitor the work that will allow generic web search engines (google, bing etc) to view and discover information within CSW catalogues.

B) Improve the quality of geospatial data by setting out common standards, schema, metadata and identifiers

- Identify priority public sector datasets to address the issue of inconsistent use of standards, unique persistent identifiers, schemas and data lifecycles.

C) Encourage re-use of geospatial data in ways that minimise duplication of data

- APIs provide simplified access to data and offer an interface that exposes this data (and functionality) for the development of new applications, allowing the reuse of data and capabilities across a variety of services. They can be used as both a data delivery mechanism or a value-added service. Need to ensure technical standards are followed and end user support provided.

- Scottish Government already procures a data service wherein members of OSMA have access to data via a range of Web Services to give instant up to date access, reducing reliance on their own organisations IT infrastructure. Would like to see the range of data that is available by this route increase to include other data (eg. BGS data, UKHO, satellite and other EO (Q6))

- Many of the standards for geospatial are clearly defined in the EU INSPIRE Directive. The Directive requires member states to put in place mechanisms to make spatial data available to citizens and organisations. This means data must be published in a consistent format and web services created for accessing the spatial datasets. There is a need to up-skill the public sector on recording INSPIRE metadata, using the UK metadata standard Gemini (version 2.3 at present) which is machine readable and can be queried. Knowing what INSPIRE data and services are available and if relevant depends on the quality of metadata. It is also worth noting that the UK is a signatory to the United Nations Sustainable Development Goals (UNSDGs) which run to 2030 and have 169 targets, 78 of which have spatial data elements. UN Global Geographical Information Management (UNGGIM) is leading this work and will base its reporting mechanism for the spatial elements of the UNSDGs on the framework set out in the INSPIRE Directive.
- Multiple different licencing regimes making reuse complex. There are too many agreements and the interfaces between are often muddy.

Q13. How can the Geospatial Commission act as a more effective customer for geospatial data on behalf of the public sector?

A) Encourage and support collaborations (be that data procurements or specific projects) within the public sector and help us understand how we can work more closely with private sector and academia. There are numerous government initiatives to do this but signposting these would be helpful (i.e. UK Innovate funding)

B) Point to relevant standards on accessibility, data and metadata as well as more general best practise for geospatial professionals

C) Engage with the professional schemes (GSE and DDATs) to develop basic skill set for geospatial professionals

D) Raise awareness of geospatial amongst public sector leaders

Q14. Are there any additional geospatial datasets, from the other partner bodies or other sources, that the public sector would derive significant benefit from having access to, that might have novel and valuable use cases? What would that access look like?

Other geospatial datasets that we could derive significant benefit from are:

- National LiDAR coverage - There are several key advantages to the acquisition of a national LiDAR dataset to capture the nature of the physical landscape of Scotland both in terms of meeting statutory objectives and duties for a number of public sector organisations (SEPA, SNH, FC) but more widely in aiding informed decision making on the basis of common, up-to-date and accurate data being available. The main policy areas are those involved in critical national infrastructure management, flood risk management, the forest industry and environmental monitoring but could also be used for planning purposes.
- MET Office data – currently only accessible in obscure formats
- High resolution satellite data
- Access to commercial broadband network information – Superfast Broadband Reaching 100% programme

Q15: How can we best develop a single UK strategy, ensuring alignment between the individual strategies across the UK while still allowing for regional variations?

Think of the strategy as a process of collaboration – define the process, understand the existing alignments (for example Inspire and EO), develop frameworks to work under were there may be variation in alignment for the individual strategies to fit under, set clear lines of communication and look at and learn from projects that have worked (for example Google project Aristotle and the Defra EO Centre of Excellence resourced by JNCC).

Q16: How can we best ensure effective local authority coordination and sharing of best practise, using location data to better deliver public services?

Scottish local government creates and maintains an extensive asset of geospatial information with significant value both within the public sector and to external organisations. However, the quality of individual datasets is inconsistent, reflecting historic priorities across councils and within different internal services, as well as the overall resources and capabilities available for ongoing maintenance.

The data asset is generally stored in departmental systems and silos and is largely inaccessible, under-used and consequently under-valued, therefore the resources available to maintain it have noticeably deteriorated in recent years.

Whist the data may continue to support the core functions for which it was created, there are significant barriers to unlocking the economic and public value. Market research suggests that opening access to the data could support at least £320M of economic activity at UK levels (based on a 5% share of the existing market) and support a wide range of commercial opportunities in land, property and planning, generating economic activity and supporting the local government tax base.

There is strong evidence of increasing demand for access to local authority spatial information with many organisations expressing frustration at the current time-consuming process involving contacting 32 different organisations, who may or may not provide access, and then discovering that the data doesn't meet the intended purpose. The Improvements Service SpatialHub has been gradually developed over the last three years and has well established business processes for the upload, quality assurance, collation and publishing of spatial datasets. The Spatial Hub provides access to quality assured local authority geospatial data through a single point through an (API). Future plans may involve:

- Benchmark for dataset quality - completeness and quality assurance.
- Review data standards, in terms of relevance and feasibility.
- Agree and implement data improvement programmes for datasets
- Harden and scale up infrastructure

Q17: As a result of this analysis, we are prioritising the exploration of possible initiatives in the high-value categories identified:

- **property and land**
- **infrastructure and construction**
- **mobility**
- **natural resources**
- **sales and marketing**

What are the existing or potential geospatial applications which could be scaled-up or developed in order to capture economic value? (We would particularly welcome responses from industry and other bodies engaged in these sectors.)

Dial before you dig – upscale this system used by Local Government to look at bin, gritting routes, meals on wheels.

Q18: Are there any other areas that we should look at as a priority?

Integration of geospatial data with business intelligence

Health and social care and the linking geospatial to health data

Q19: What are the main potential private and public sector innovations that will rely on the use of geospatial data to rollout, and are there corresponding regulatory challenges?

A) PARD (Persons at Risk Distribution) is a concept that has been pioneered by several local authority areas in Scotland and also in partnership with NHS Scotland along with emergency responders and other supporting organisations. The system is a means whereby a local authority can rapidly identifying a person or persons at increased risk during an emergency due to their proximity and vulnerability to a threat while prioritising support or evacuation to those persons if required.

The PARD system is compatible with any local authority social work data system and mapping system. The capital costs in building the system architecture within NHS NSS environment has already been met by the National Centre for Resilience (NCR) when they commissioned the implementation of the PARD system. The system will provide each local authority with the required data from health records to identify the vulnerable within that local authority area in the event of an emergency

As part of the process the NCR commissioned and funded the NHS NSS to geocode each individual health care record with a Unique Property Reference Number (UPRN's). These health care records would then be securely stored within folders, with each individual Local Authority only having access to their own health care data in the event of an emergency and subsequently deleted after the event. This process is essential to the success of PARD.

B) UAV's and regulation by CAA

Q20: How best can we make the UK's presence in the international geospatial world more visible?

The UK needs to take a more active role in the international geospatial world (i.e. Inspire and EO conferences) and this active role should not just sit with Ordnance Survey or others in the 6 Partner Bodies (Geo6) who can afford the travel/ conference costs but, with the help of resources, should be opened up to a wider set of organisations.

Q21: Where should the UK be looking for points of comparison overseas? Who are the other international exemplars? What best practice is being modelled overseas that we can learn from?

- Smart cities – Singapore
- Centralised lists of accessibility and data standards and APIs - Netherlands

Thank you for your time in completing your response to our call for evidence.

Any questions, please get in touch with the Geospatial Commission via geospatialcommission@cabinetoffice.gov.uk

[Text Redacted]

Hello,

I know this is officially late, so my apologies for that. I just wanted to make you aware of Shared Assets' Land Explorer project.

We are a social enterprise think and do tank that supports people and organisations managing land for the common good. We support the development of new business and governance models and work to create the conditions in which common good land users can thrive. We support a range of common good land uses, from organic and community supported farming, to urban agriculture and community gardening, woodland-based social enterprise and community run public spaces.

A common barrier that many of the organisations we work with come up against is the lack of accessible and usable information on land. We carried out some research in 2016 that explored a number of these issues, and highlighted the potential for significant social and civic value to be created from government data on land.

We then sought some charitable funding to create a mapping platform, Land Explorer, which aims to bring useful data on land together with an easy to use mapping interface, with sharing and drawing tools. It's in its beta testing phase now and you can access it here: www.landexplorer.cc. We have been working closely with both Ordnance Survey, to integrate their base maps and deal with the associated licensing issues, and with Land Registry, to make some ownership data available to our users (this is still in development).

We believe that better access to public geospatial data could unleash a huge amount of civic creativity and enterprise that will have benefits for communities, the environment and the economy. We'd love to come and discuss this potential further with you and explain more about how we're creating Land Explorer, if that would be helpful.

all the best, and apologies again for the late response,

[Text Redacted]

Geospatial Commission: Call For Evidence Response Questionnaire

Please submit your completed questionnaire to:

geospatialcommission@cabinetoffice.gov.uk.

Clearly title your email *'Call for evidence response'*.

About you and your organisation

Large business (over 250 staff)	
Medium business (50 to 250)	

Small business (10 to 49)	
Micro business (up to 9)	
Other - please state	

Call for evidence - three key themes

We have identified three high-level themes that could help our approach to setting a strategy which are as follows:

1. **Supporting innovation in the geospatial sector**, exploring how to secure cutting edge skills, the right access to data, and opportunities from emerging technologies for the geospatial sector itself
2. **Enhancing the UK's geospatial assets,** looking at how best to align interests, avoid duplication, and instill best practice across the whole public sector
3. **Driving investment and productivity in geospatial applications**, asking in which wider sectors the most value lies from better exploitation and use of geospatial data, in the UK and internationally

Our questions

Q1. Is our view of the geospatial data types accurate? If not, what should be included or excluded from this?

Data type 4 "Higher-level insights and products" looks distinct. Data types 1 and 2 look as though they are not easily distinguished from one another and the distinction may be essentially subjective, depending on which agency is using the information. Moreover, all data has to be geo-tagged if it is to be represented on a map. For purposes of urban and regional policy and planning, the main field of application with which we are familiar, it would be better to distinguish between
- background spatial data (social patterns and physical topography);
- operational data (generated by operators such as water companies, bus companies, planning departments etc);
- data that shows the views and wishes of residents, citizens and consumers as for example revealed in the social media and local consultation exercises and finally
- data that maps activities, risks and flows of various types (traffic flows, energy use, flood risk, crime, pollution etc).

Q2. In addition to current government policy, what are the areas of geospatial skills where the commission could best focus, to help ensure the necessary capability within the UK for the future?

The development of geospatial skills has to start at secondary school, including within the A level geography curriculum. A detailed examination needs to be made to determine whether the existing curriculum, as interpreted in schools and by examiners, develops an adequate awareness of geography as an exercise in spatial science. The main issues are the emphasis placed on quantitative data and on fieldwork. The current geography syllabus may be a little old-fashioned in assuming that researchers go out and collect new data, through fieldwork, rather than analyse existing data sets or use existing web-based material.
The issues with geography in schools have to be looked at in the context that by international standards, adult numeracy amongst is poor in England, according to an OECD report (2016) Building Skills for All: A Review of England. This being so, a wide ranging educational strategy will be necessary.
The creation of apprenticeship degrees is an established aspect of government policy for higher education and it is recognised in the Geospatial Commission Consultation. The potential of apprenticeship degrees deserves to be given prominence, both in terms of dedicated geospatial and geography degrees and in degrees in related fields, notably spatial planning.
There are specific skills, for example, in artificial intelligence, in network analysis and in raster analysis that may need more emphasis in the geography and GIS syllabus at undergraduate and postgraduate levels. The emphasis varies in different universities. The main need is for graduates who are generally skilled in digital and quantitative socio-spatial analysis and are adaptable for the future. The precise balance of skills is often difficult to predict and will in any case change over time. We would, nevertheless, suggest that the Geospatial Commission undertakes a scoping study to determine exactly what is taught in UK universities in existing GIS courses.

Q3. What are the geospatial skills needs and gaps in your organisations, how can these be most effectively addressed, and how can careers in the sector be best promoted?

As is common in the field of computing and information technology, it is often not easy to find skilled staff for research or for teaching.
Sheffield Hallam University runs a full time, one year long MSc in Geographical Information Systems (https://www.shu.ac.uk/courses/geography-and-environment/msc-geographical-information-systems/full-time) whose graduates are very much in demand with a variety of employers. To counter shortages of skilled staff, the government could consider establishing a limited number of postgraduate bursaries. The availability of bursaries would help publicise the existence of current MSc courses and promote spatial science as a distinct career.

Q4. Are there any publicly or privately-held geospatial datasets that are currently challenging to access or use or of insufficient quality, but which you or your organisation would find valuable if these issues could be resolved? Please explain why this would be of value, and how access/quality could be improved?

Much of the experience of staff at Sheffield Hallam University is in the field of applied knowledge, working with private businesses and the public sector and working in particular in the fields of urban and regional policy, urban development and urban planning. In that context, the main issues are less systemic data accuracy and more concerned with usability, access and interoperability.
Issues of access also arise for staff who work in the physical geosciences. A substantial element of this work relies on satellite imagery. Almost all currently collected publicly funded imagery from NASA and the ESA is freely available. However, some legacy data is difficult to obtain. Much data that is privately held (e.g. TerraSAR-X, Worldview, etc) is cost prohibitive for use in many academic projects, both for research or for teaching and skills development. Some new private companies are adopting policies of making their data (which is commercially very expensive) freely available for academic use. Planet.com is an example of this. Encouraging and promoting this kind of free sharing of commercial data for academic use should be part of the geospatial strategy.

Q5: Do you anticipate that any changes will be needed to the both address data and the wider address ecosystem, to support emerging technologies? Please provide evidence of value to support any proposed changes.

The consultation document is correct to state that more needs to be done to ensure that geo-tagging and geo-addressing is undertaken on a more systematic and mutually recognising basis.

Q6: How should the commission be looking to develop the UK's capability in Earth observation data, both technologically and to support an effective market?

See answer to Q4.

Q7. Which new technologies should the commission focus on to provide new opportunities to process and exploit geospatial data for economic growth?

In the applied policy field, artificial intelligence is the most promising, relatively new technology. Artificial intelligence is relevant to the making projections of the future, from all spatial levels from the street and neighbourhood to a city region and beyond. AI can also be used in risk analysis of various types and in product development (though this is not necessarily a geospatial issue). A national geospatial commission needs to encourage existing specialists in AI to take an interest in spatial issues and to work alongside those who already use geospatial data. To facilitate such an exchange of ideas, the Geospatial Commission needs to have strong representation from the universities within its membership as well as from the professions who use geospatial data. The professions include the Royal Institution of Chartered Surveyors and the Royal Town Planning Institute. A further priority, in which AI is probably also of relevance, is to link geospatial analysis to urban design and building information software, so creating visual, three dimensional scenarios of help to architects and developers.

Q8. How can geospatial data and applications be used to support enhanced roll-out of future technologies?

See the answer to Q4.

Q9: What are the options for how public sector organisations could continue to invest in maintaining and enhancing our geospatial data assets?

See the answer to Q4.

Q10: What areas of the underpinning geospatial infrastructure such as positioning technologies, including GPS and indoor positioning systems, and geodetic networks and frameworks to support them, should we be prioritising the development of, in order to support the emerging requirements for geospatial data?

The main priority is for the better use and integration of data and information already available rather than the acquisition of new data.

Q11: What role should the private sector have in both the development and maintenance of the underpinning infrastructure and enhancing the UK's geospatial data assets?

The private sector, often small companies, has been useful in generating small-scale applications. There are, however, limitations to the role of the private sector. First, government needs to be alive to situations in which a small number of consultancies have acquired data through their previous experience and are able to charge non-competitive fees for its release or for undertaking analytical work. Secondly, a reliance on the private sector tends to work against innovations that depend on common digital platforms linking data from a multiplicity of different agencies. Common digital frameworks require agreement and standards and more or less universal application if they are to work.
Thirdly, as has been documented elsewhere neither private nor public sector agencies have shown enthusiasm for innovations in the field of promoting or measuring environmental sustainability and liveability in towns and cities. See, for example the following report: the United Nations University Institute for the Advanced Study of Sustainability (2017) Policy Brief 12, Sustainable Smart Cities:Applying Complexity Science to Achieve Urban Sustainability, Policy Brief 12

Q12. Do you face challenges when working with geospatial data from across the public sector? If so, what are they and how could value be better released? Are there any technical remedies or standards that could be adopted to improve the interoperability of geospatial data? Please provide supporting evidence of what these remedies could help to accomplish.

Researchers and staff at Sheffield Hallam University have used local public sector data. The main issue is that the data has been collected according to varying local practices over many years and also contains non-systematic inaccuracies and errors. There is, therefore, no simple technological device that might offer a solution to existing deficiencies. Data has to be checked manually. Once data is 'cleaned', there are established technologies, for example those concerned with semantic or ontological databases, that provide a flexible means of relating information from multiple sources. Evidence is available from the published academic literature.

Q13. How can the Geospatial Commission act as a more effective customer for geospatial data on behalf of the public sector?

There are real issues of security, personal confidentiality and commercial confidentiality in the public release of data. In some cases, the confidentiality and security rules are themselves confidential and not reported with the result that the public and independent researchers do not know the range of data that might be released. A key role for the Geospatial Commission might be review the data release practices to determine whether security and confidentiality rules are justified. The Geospatial Commission would, therefore, most likely acquire a regulatory role in the release of data. The preparation of standards covering such issues as geolocation and spatial scalability would also be a useful role.

Q14. Are there any additional geospatial datasets, from the other partner bodies or other sources, that the public sector would derive significant benefit from having access to, that might have novel and valuable use cases? What would that access look like?

Local energy and heat use data could be greatly improved. Data exists in the records of electricity companies, gas supply companies and in some places district heating agencies. If these various sources could be aggregated and geo-coded according to a common framework, the results would be most beneficial in identifying priorities in energy savings and carbon reduction measures. Issues of privacy and confidentiality would have to be resolved- so this is a project that would be well suited to a Geospatial Commission.

Q15: How can we best develop a single UK strategy, ensuring alignment between the individual strategies across the UK while still allowing for regional variations?

The existing Ordnance Survey maps offer an excellent example of UK geospatial coverage. A common regulatory and funding framework could encompass all regions in England and Wales. A common framework does not prevent distinct applications in different regions. Property law and property institutions in Scotland are distinct, however, so suggesting some variations in approach. Scottish devolution laws might also require other variations.
Digital innovation in the UK is promoted centrally by the Research Councils, Innovate UK and the Digital Catapults. The regional distribution of funding from these agencies deserves very much more attention in case they exacerbate long standing trends towards public and private investment being concentrated in London and south east England. To promote balanced regional development, the Geospatial Commission should have its main office outside London and south east England.

Q16: How can we best ensure effective local authority coordination and sharing of best practise, using location data to better deliver public services?

Many local authorities lack the capacity, either in staff resources or expertise, to promote digital innovation and digital co-ordination in the delivery of public services. Local authorities face many other competing demands and have operated in a context of declining resources. Digital innovation offers a potential means whereby local authorities can improve the quality of their services, without additional major staffing implications. However, digital innovation has start-up costs and the uncertainty about the detailed application of various technologies also causes delays and further costs. Local authorities will require some form of direct financial assistance, for example a digital innovation grant and continued advice and support.

Q17: As a result of this analysis, we are prioritising the exploration of possible initiatives in the high-value categories identified:

- **property and land**
- **infrastructure and construction**
- **mobility**
- **natural resources**
- **sales and marketing**

What are the existing or potential geospatial applications which could be scaled-up or developed in order to capture economic value? (We would particularly welcome responses from industry and other bodies engaged in these sectors.)

There are multiple sources of data and information in the above categories, the relevance of many only become relevant in the context of specific tasks and research exercises. Identifying information requirements is likely to prove an on-going process.
In terms of immediate priorities, the following are suggested:
First, a cadastral map of England and Wales showing the totality of registered real rights in land and bringing together the information currently held by the Land Registry. The Scottish Government is already moving in this direction and private companies are collating data from a variety of sources. It would be of help if the preparation of a cadastral map were placed on a statutory basis.
Secondly, a parallel map of local planning decisions and policies. There are now examples of digital planning maps from London, Manchester and Sheffield and elsewhere. The details vary, however and the treatment of details, for example the boundaries of the sites of listed building or of scientific interest could be improved. The efforts of local authorities need to be undertaken to a common framework and standardised. The data and information sources used by local authorities also needs to be machine-readable, as is widely recognised and geo-tagged.
A combination of a detailed digital cadastral map, a detailed policy map and the existing Ordnance Survey topographical maps would greatly facilitate the identification of local development opportunities and local spatial planning. It should be noted, however, that development is also dependent on the location of infrastructure. Better and more comprehensive infrastructure mapping, including the underground infrastructure, this latter being recognised in the consultation document, is also required.

Q18: Are there any other areas that we should look at as a priority?

Health and liveability are an obvious omission from the list of high value information categories. Health and liveability go together (good quality housing, clean air, access to green spaces) and are central to public policy debates. Liveability is also central to the competitiveness of different towns and cities.

Satellite imagery is generally crucial to the health of the geospatial economy. The space sector has some of the highest levels of growth, GVA, and export share within the UK economy. Arrangements post-brexit must not be allowed to threaten this.

Q19: What are the main potential private and public sector innovations that will rely on the use of geospatial data to rollout, and are there corresponding regulatory challenges?

Social media can be used for sales and marketing and for mapping the location of a very wide range of commercial, cultural and recreational activities. The dominance of particular companies in the field of social media and the ownership of social media data are potentially serious issues.
Artificial intelligence, like the use of computerised models, requires ethical codes and codes of good conduct when applied either to the public sector and urban governance or to individuals. These codes would cover the reliability of the data, the transparency of their use and the avoidance of personal or community harm. The European Commission is currently preparing ethical guidelines (http://europa.eu/rapid/press-release_IP-18-3362_en.htm). These go beyond geospatial data, but it surely will be important that, after Brexit, the UK government develops parallel and probably similar guidelines.

Q20: How best can we make the UK's presence in the international geospatial world more visible?

The UK has a strong presence amongst international architectural, engineering and planning consultancies capable of advising governments on large-scale and long-term patterns of urban development, including sustainable development. Indeed there are only a few countries in the world with large consultancies active in this particular field. It might therefore be worthwhile for the UK government to work with and to promote relevant UK consultancies and UK universities active in this field.
Innovation and growth in all aspects of the geospatial sector is strongly linked to the work of universities, both through the provision of a highly skilled workforce, and through the conduct and communication of high impact research. These dependencies are particularly important for start ups and SMEs. As such, the lack of reference to universities and the links between universities and industry, in the consultation strategy is of concern.

Q21: Where should the UK be looking for points of comparison overseas? Who are the other international exemplars? What best practice is being modelled overseas that we can learn from?

NASA and the ESA (European Space Agency) are exemplars of current best practice in terms of the open sourcing and online distribution of data collected using public funds. Otherwise, geospatial skills and analysis are so widely used that it is probably best to look at those countries, notably those in east and south east Asia, that already have good standards of technical education and high levels of numeracy. The future depends on the availability of a skilled workforce as is recognised in the first few questions in this questionnaire.

Thank you for your time in completing your response to our call for evidence.

Geospatial Commission: Call For Evidence Response Questionnaire

Please submit your completed questionnaire to:

geospatialcommission@cabinetoffice.gov.uk.

Clearly title your email *'Call for evidence response'*.

About you and your organisation

Name	[Text redacted]
Organisation	Skanska UK

Legal representative	
Local government	
Large business (over 250 staff)	**X**
Medium business (50 to 250)	
Small business (10 to 49)	
Micro business (up to 9)	

Other - please state	

Call for evidence - three key themes

We have identified three high-level themes that could help our approach to setting a strategy which are as follows:

1. **Supporting innovation in the geospatial sector**, exploring how to secure cutting edge skills, the right access to data, and opportunities from emerging technologies for the geospatial sector itself
2. **Enhancing the UK's geospatial assets,** looking at how best to align interests, avoid duplication, and instill best practice across the whole public sector
3. **Driving investment and productivity in geospatial applications**, asking in which wider sectors the most value lies from better exploitation and use of geospatial data, in the UK and internationally

Our questions

Q1. Is our view of the geospatial data types accurate? If not, what should be included or excluded from this?

Geospatial data: Information where ~~place~~ **location** is a key feature of its source and/or purpose for which it is used.

Positional data: Groups of individual datasets that usually have location as a secondary purpose, and which describes activity or physical assets grounded in a particular place.
We call this attribute data in the survey world.

Geospatial identifiers: Data that provides the means of anchoring positional data to core geospatial data. Is going to include date for currency knowledge?

Geospatial services: Higher-level insights and products, often involving layers of various types of spatial information. No comment

Q2. In addition to current government policy, what are the areas of geospatial skills where the commission could best focus, to help ensure the necessary capability within the UK for the future?

1. (Early years) From the unskilled infant to the highly skilled adult we all use of digital mapping and the things that change are the content and accuracy of the data. This can be taught to fun through sports linked to geospatial data. Geocaching, orienteering etc.
2. Business will find the best to use of data to drive efficiency, however common formats or national standards do not exist. I think the geospatial commission should be more parental and insist on a standards linked to naming and coding.
3. In the initial analysis document geospatial data linked to sales and marketing is mentioned, this same approach could be used for public notices and information. Also are advertising distractions linked to accident black spots?

Q3. What are the geospatial skills needs and gaps in your organisations, how can these be most effectively addressed, and how can careers in the sector be best promoted?

1. Teachers and careers advisors do not know that these opportunities exist. The website Geomatics.org was set up to help geo-careers be known to the teachers at an early age. A central careers hub is need in the right place on the web.
2. Clients do not know what data to collect and retain (we have gone from clip board to iPad in under 20 years), this means that UKPLC is working in different directions. Employer Information Requirements (EIR) should be part of project start up and include SPECFIC. Geospatial data capture requirements.

Q4. Are there any publicly or privately-held geospatial datasets that are currently challenging to access or use or of insufficient quality, but which you or your organisation would find valuable if these issues could be resolved? Please explain why this would be of value, and how access/quality could be improved?

Land ownership and conveyancing is out of data always and the greatest purchase you make in your life is in the hands of people that do not understand geospatial data. Conveyance surveys that measure the geospatial location and the attribute data would be serve the housing market and the land registry. Lost land or unregistered would become a thing of the past if, surveyors had to measure the footprint of what was going too conveyed. This would assist planning authorise and the utility companies in their service proposals.

Q5: Do you anticipate that any changes will be needed to the both address data and the wider address ecosystem, to support emerging technologies? Please provide evidence of value to support any proposed changes.

1. Postal addressing in high raised apartment blocks is not linked to the actual height of a building and with the opportunity of drones delivering to the right address, the altitude in an address would enable the opportunity for safer delivery of parcels, or in the case of emergency drones a faster response. EG if Flat 6 on floor 3 was actually Flat 6 floor 18m you would have more data just be changing the addressing system.

Q6: How should the commission be looking to develop the UK's capability in Earth observation data, both technologically and to support an effective market?

The UK should invest in the state of the art imagery for the UK and its territories. The construction, surveying and planning could use this data to better evaluate concept design, survey, construction progress and the maintained asset.

Q7. Which new technologies should the commission focus on to provide new opportunities to process and exploit geospatial data for economic growth?

The commission should focus applying what is good in one area and rolling it out nationally.
The use of "fix my street" or a consistent app that helps report issues and to local government. I find a good response time when using the app near my home. However other areas do not use it. This provides a real measure of what is reported, where, where and when it was resolved. This enables operational efficiency. An example of this would be that local authorises use roadworks.org and Highways England did not.(This may have changed)

Q8. How can geospatial data and applications be used to support enhanced roll-out of future technologies?

This subject is vast. We see this already in many apps already from warning in sat navs about speed cameras and speed limits linked to cameras on cars.
If the geospatial data of the infrastructure asset was mapped the orientation of vehicles travelling would have a more precise a location, due to software that will anticipate an obstacle. Autonomous vehicle assistance.

Accident blackspots would be recorded and assist the travelling public.
QR codes that displayed at the location of the advert or information poster will capture the best location to advertise.
Internal mapping of public buildings would ensure that people are able to find the location they require more easily.

Q9: What are the options for how public sector organisations could continue to invest in maintaining and enhancing our geospatial data assets?

???

Q10: What areas of the underpinning geospatial infrastructure such as positioning technologies, including GPS and indoor positioning systems, and geodetic networks and frameworks to support them, should we be prioritising the development of, in order to support the emerging requirements for geospatial data?

1. GPS (American satellites only) is not the term GNSS Global Navigation Satellite System (Russia/American/European/World).

2. The linear referencing system used along our infrastructure (marker posts) do not have a linear reference that could refer to all other assets along that route. Simple naming convention changes to use a linear reference system backed up with a geospatial position would help the building and maintenance of those infrastructure routes.
EG on the M1 motorway, the lampposts will be numbered 1/2/3/4 north or south bound. However the French toll road method would name them at linear distance along the route. 50/100/150/200. You can now see the lamppost is 50m apart and the distance along the route. If all street furniture was labelled in this manner it would aid the travelling public, the maintainer and the emergency services.

3.Lorawan The LoRaWAN™ specification is a Low Power Wide Area (LPWA) network protocol designed to wirelessly connect battery operated 'things' to the internet in regional, national or global networks.

Q11: What role should the private sector have in both the development and maintenance of the underpinning infrastructure and enhancing the UK's geospatial data assets?

The professional membership bodies and the private sector are writing client guides and standards while collecting data as per the client requirements. We are self-developing.

It is fundamental that the private sector innovate change, write standards and propose those standards, via professional routes. The Survey Liaison Group undertake this using members from ICES, RICS, and TSA.
https://www.cices.org/
https://www.rics.org/uk/
https://www.tsa-uk.org.uk/

The military have a large part to play in the capture and reuse of data and should be forgotten today's service man is tomorrows civilian and their mapping skills will be useful.

The clients see data capture this as a cost, a very short term view.
Legacy data capture is fundamental and should look past the current client.
Legacy data should be targeted at the main groups, beyond the current client Ordnance survey etc.

Q12. Do you face challenges when working with geospatial data from across the public sector? If so, what are they and how could value be better released? Are there any technical remedies or standards that could be adopted to improve the interoperability of geospatial data? Please provide supporting evidence of what these remedies could help to accomplish.

1.Highways England use a mapping system that differs from Network Rail for engineering reasons(local grids).Those old mapping guidelines still apply, however how the population interacting with those maps has grown to a size that engineering reasons may be better solved locally, rather than over the project length. The majority of “mobile device” technologies do not unlock the potential due to local grids.

2. The compulsory adoption of best practice converted into client/commission requirements EG PAS 256 for utility location recording. The funding of BSI “geospatial “documentation should be funded by the government instead of private industry funding what is meant to be a national standard.

Q13. How can the Geospatial Commission act as a more effective customer for geospatial data on behalf of the public sector?

The Geospatial Commission (in line with their operating principle 2:2.1g) should fund a project to deliver a Topographic National Feature Code Library hosted by the Ordnance Survey using the relationship with partner body’s governance (5:5.8). The Survey instrument manufactures and software houses would adopt this National Standard. When Geospatial data is then collected via a survey device it would be in the right format from the first opportunity ensuring ease of interoperability.

Q14. Are there any additional geospatial datasets, from the other partner bodies or other sources, that the public sector would derive significant benefit from having access to, that might have novel and valuable use cases? What would that access look like?

Environmental incidents in a geospatial layer. The Environment Agency did have “what is in your backyard” service which was removed after 20 years. This has been replaced with a system that members of the public may struggle with.

Q15: How can we best develop a single UK strategy, ensuring alignment between the individual strategies across the UK while still allowing for regional variations?

Q16: How can we best ensure effective local authority coordination and sharing of best practise, using location data to better deliver public services?

1. Ensure the local authority team is made up of specifically identified job roles linked to the geospatial data.
2, Telematics on local authority vehicles.

Q16: As a result of this analysis, we are prioritising the exploration of possible initiatives in the high-value categories identified:

- **property and land**
- **infrastructure and construction**
- **mobility**
- **natural resources**
- **sales and marketing**

What are the existing or potential geospatial applications which could be scaled-up or developed in order to capture economic value? (We would particularly welcome responses from industry and other bodies engaged in these sectors.)

1. Patient Health recovery times, did they recover at home, hospital or other.
2. Poor health attendance mapping, check-ups, appointments etc. This would then lead to a targeted education roll out.

Q18: Are there any other areas that we should look at as a priority?

Standards or standard gaps and where they align to the NGS.

Q19: What are the main potential private and public sector innovations that will rely on the use of geospatial data to rollout, and are there corresponding regulatory challenges?

1. Emergency service response with future drone or autonomous fire engines. CAA rules and undefined flight corridors for service drones.

2.Autonomus deliveries and construction equipment

Mixed reality data awareness in construction and other industry would work better in this theatre. Adherence to PAS 256/128

Q20: How best can we make the UK's presence in the international geospatial world more visible?

Be the first nation to have a national feature code library for surveying.
Support geomatics.org for careers advice
Use schools to host Geoinovation hubs
Remove VAT on GIS software for the next 10 years, to encourage adoption

Increase the Territorial army training in GIS.
Support Map Action, the charity, this could be linked to the armed forces.

Q21: Where should the UK be looking for points of comparison overseas? Who are the other international exemplars? What best practice is being modelled overseas that we can learn from?

Look at Australia and our old colonies for cadastral, Germany and their cadastral service.
Take to power of opinion from paper and solicitors and drive in the fact of digital geospatial data via appropriate accuracy.

Thank you for your time in completing your response to our call for evidence.

Any questions, please get in touch with the Geospatial Commission via geospatialcommission@cabinetoffice.gov.uk

Geospatial Commission: Call For Evidence Response Questionnaire

Please submit your completed questionnaire to:

geospatialcommission@cabinetoffice.gov.uk.

Clearly title your email *'Call for evidence response'*.

About you and your organisation

Legal representative	
Local government	
Large business (over 250 staff)	
Medium business (50 to 250)	
Small business (10 to 49)	
Micro business (up to 9)	**X (niche business)**
Other - please state	

Call for evidence - three key themes

We have identified three high-level themes that could help our approach to setting a strategy which are as follows:

1. **Supporting innovation in the geospatial sector**, exploring how to secure cutting edge skills, the right access to data, and opportunities from emerging technologies for the geospatial sector itself
2. **Enhancing the UK's geospatial assets,** looking at how best to align interests, avoid duplication, and instill best practice across the whole public sector
3. **Driving investment and productivity in geospatial applications**, asking in which wider sectors the most value lies from better exploitation and use of geospatial data, in the UK and internationally

Our questions

Q1. Is our view of the geospatial data types accurate? If not, what should be included or excluded from this?

Include : making the substantial geospatial assets acquired by UKGov (presumably with tax payers' money) more widely available to the UK public and businesses.

This can be best achieved via specialist companies and partners, on a sensible commercial basis. This would benefit both parties; the UKGov receives a return on their investment in acquiring the geospatial resources and the UK private and corporate sectors would receive access to valuable geospatial information, much of which is currently locked away or generally unavailable.

Q2. In addition to current government policy, what are the areas of geospatial skills where the commission could best focus, to help ensure the necessary capability within the UK for the future?

I am only qualified to speak on aerial photographic and related matters and in this sector I see barriers and lost opportunities.

Q3. What are the geospatial skills needs and gaps in your organisations, how can these be most effectively addressed, and how can careers in the sector be best promoted?

Increased training in GIS programmes and methods will always be effective in increasing skill sets. There are specialist geospatial trainers.

The online data providers such as Google Earth and Bing Maps have massively increased awareness of mapping and aerial imagery over the last 20 years of the digital age. Nowadays consumers expect to find and utilise these products on the move. Promotion of careers in the geospatial sector can be linked to the use of these online web sites and products.

Q4. Are there any publicly or privately-held geospatial datasets that are currently challenging to access or use or of insufficient quality, but which you or your organisation would find valuable if these issues could be resolved? Please explain why this would be of value, and how access/quality could be improved?

Yes.
Again speaking about aerial photography and related datasets only, there is a huge demand for these products but there are considerable challenges in accessing and using the data responsibly.
This is not helped by the mistakes displayed in some large and well known online geospatial datasets which are causing problems in the planning and legal sectors.
This is my area of expertise and the question about improvements is complicated and not for this questionnaire.

Q5: Do you anticipate that any changes will be needed to the both address data and the wider address ecosystem, to support emerging technologies? Please provide evidence of value to support any proposed changes.

I have no expert knowledge of this subject.

Q6: How should the commission be looking to develop the UK's capability in Earth observation data, both technologically and to support an effective market?

I have little expert knowledge of high level Earth observation data, although I know of companies providing such imagery.

Q7. Which new technologies should the commission focus on to provide new opportunities to process and exploit geospatial data for economic growth?

I have no expert knowledge of this subject.

Q8. How can geospatial data and applications be used to support enhanced roll-out of future technologies?

A thought only. Thanks to Google Earth, Bing Maps and similar data providers, geospatial data is a way of life and must be factored into future technologies where it will become increasingly important.

Q9: What are the options for how public sector organisations could continue to invest in maintaining and enhancing our geospatial data assets?

By making the data assets available to offset costs in acquiring.

As technologies improve, there will be a continual need to invest to keep up to date with new equipment and software. Therefore make the results of the acquisition available more widely to bring about a financial return.

Q10: What areas of the underpinning geospatial infrastructure such as positioning technologies, including GPS and indoor positioning systems, and geodetic networks and frameworks to support them, should we be prioritising the development of, in order to support the emerging requirements for geospatial data?

I have no expert knowledge of this subject.

Q11: What role should the private sector have in both the development and maintenance of the underpinning infrastructure and enhancing the UK's geospatial data assets?

I suggest using joined up thinking.

In my specialist sector of aerial surveying, the capital costs and investment of resources to capture and maintain geospatial information is huge. The private and public sectors could work together to avoid duplication of effort and share both the costs and the rewards. This is beginning to happen but could be improved.

Q12. Do you face challenges when working with geospatial data from across the public sector?If so, what are they and how could value be better released? Are there any technical remedies or standards that could be adopted to improve the interoperability of geospatial data? Please provide supporting evidence of what these remedies could help to accomplish.

Yes, our company faces challenges, particularly with Ordnance Survey (England).

There are suggested remedies but I prefer to discuss them in person with OS to see how the value could be better released.

Ordnance Survey (Northern Ireland) have been the opposite and their helpful attitude is commendable.

Q13. How can the Geospatial Commission act as a more effective customer for geospatial data on behalf of the public sector?

I can only offer suggestions for aerial photography and related imagery.

We often act on behalf of the public sector and I would welcome the Geospatial Commission opening the way for better access to geospatial data held by UKGov. There may be possibilities but there is no quick answer for this questionnaire.

Q14. Are there any additional geospatial datasets, from the other partner bodies or other sources, that the public sector would derive significant benefit from having access to, that might have novel and valuable use cases? What would that access look like?

I can offer suggestions only for aerial photography and related imagery.

Yes, I am sure there are partner bodies who hold such datasets. Without knowing details of the partner arrangements it is difficult to offer suggestions and there are no quick answers for this questionnaire.

Q15: How can we best ensure effective local authority coordination and sharing of best practise, using location data to better deliver public services?

I have no expert knowledge of this subject.

Q16: As a result of this analysis, we are prioritising the exploration of possible initiatives in the high-value categories identified:

- **property and land**
- **infrastructure and construction**
- **mobility**
- **natural resources**
- **sales and marketing**

What are the existing or potential geospatial applications which could be scaled-up or developed in order to capture economic value? (We would particularly welcome responses from industry and other bodies engaged in these sectors.)

The majority of our clients are concerned with property and land, for planning, construction and legal issues.

There are great possibilities for developing these markets but this is the core of our business and it is not appropriate to give details here.

What would help this development is an unlocking of geospatial data held within UKGov.

Q17: Are there any other areas that we should look at as a priority?

I have no expert knowledge to offer.

Q18: What are the main potential private and public sector innovations that will rely on the use of geospatial data to rollout, and are there corresponding regulatory challenges?

I have no expert knowledge to offer.

Q19: How best can we make the UK's presence in the international geospatial world more visible?

I have no expert knowledge to offer.

Q20: Where should the UK be looking for points of comparison overseas? Who are the other international exemplars? What best practice is being modelled overseas that we can learn from?

I have no expert knowledge to offer.

Thank you for your time in completing your response to our call for evidence.

Call for evidence - three key themes

We have identified three high-level themes that could help our approach to setting a strategy which are as follows:

1. **Supporting innovation in the geospatial sector**, exploring how to secure cutting edge skills, the right access to data, and opportunities from emerging technologies for the geospatial sector itself
2. **Enhancing the UK's geospatial assets,** looking at how best to align interests, avoid duplication, and instill best practice across the whole public sector
3. **Driving investment and productivity in geospatial applications**, asking in which wider sectors the most value lies from better exploitation and use of geospatial data, in the UK and internationally

Our questions

Please note that we have chosen to respond to those questions selected by us as most relevant to the local government sector.

Q3. What are the geospatial skills needs and gaps in your organisations, how can these be most effectively addressed, and how can careers in the sector be best promoted?

Availability and sharing of relevant staff skills and knowledge is a significant factor in maximising the benefits of geospatial data for local authorities and their partners. Technical skills in specialist applications can be expensive to acquire through formal training.

Firstly, more emphasis could be given to informal sharing of knowledge and best practice though online user communities such as exist in the public service Knowledge Hub. Targeted demonstrations and case studies relevant to specific business areas can increase awareness and encourage authorities to improve skills, leading to better utilisation of data through existing or new solutions.

Secondly, development of regional/sub-regional shared centres of excellence (e.g. the Scottish Spatial Hub) offers a way to attract and maintain skills, alongside improved partnership working arrangements with universities, the private sector and others.

Q4. Are there any publicly or privately-held geospatial datasets that are currently challenging to access or use or of insufficient quality, but which you or your organisation would find valuable if these issues could be resolved? Please explain why this would be of value, and how access/quality could be improved?

The quality of spatial data captured and maintained by local authorities depends on the availability of high quality and up-to-date topographic mapping as supplied by the Ordnance Survey MasterMap products. In the case of Scotland, for example, the cost to local authorities of accessing and using such data, through membership of the One Scotland Mapping Agreement (OSMA) can be in excess of £100k per annum for each council. This annual cost is becoming an increasing financial burden that can be difficult to justify in an era of freely available online maps. MasterMap data is becoming freely available to certain groups and would therefore expect a reduction in the level of charge to the public sector customers.

Q11: What role should the private sector have in both the development and maintenance of the underpinning infrastructure and enhancing the UK's geospatial data assets?

Data standardisation and sharing within and between organisations can often depend on the technical architecture and capabilities of business-specific IT solutions, and therefore the providers of such systems should be required to fully support open standards for both data and interoperability.

Q12. Do you face challenges when working with geospatial data from across the public sector? If so, what are they and how could value be better released? Are there any technical remedies or standards that could be adopted to improve the interoperability of geospatial data? Please provide supporting evidence of what these remedies could help to accomplish.

Wider acceptance and use of location-based identifiers such as Unique Property Reference Numbers (UPRNs) and Unique Street Reference Numbers (USRNs) within non-spatial applications would enable data held in such applications to be "spatially enabled" and thereby opened up to new ways of analysis and presentation.

Tighter procurement regulations and greater vendor engagement at national level could help improve the technology used by authorities. Increased availability of standardised, open geospatial data can also help drive innovative uses of such data, for example in the availability of mobile apps.

Q16: How can we best ensure effective local authority coordination and sharing of best practise, using location data to better deliver public services?

Socitm feels that the question is phrased too narrowly. The opportunity is not just coordination and sharing of best practice in harnessing location data between local authorities, but also doing so across a wider landscape of places by involving the many different organisations that contribute to achieving better outcomes for residents, communities, employees and businesses in those places, while protecting and enhancing their environments.

Further, the use of geospatial data across these groups extends to spatial analysis, exposing patterns that cannot be identified unless this extra dimension is available.

There are many opportunities within the sector that should be addressed, and that Socitm would be keen to work with the Geospatial Commission to develop. Key amongst these are:

Promote open data (including further opening up OS mapping and address data as a public good) and open standards for data acquisition, publication and sharing.

Support and facilitate wider acceptance and use of location-based identifiers such as Unique Property Reference Numbers (UPRNs) and Unique Street Reference Numbers (USRNs) within non-spatial applications. This particularly problematic in respect to sharing data across social care, emergency and health services as certain organisations incorrectly regard street and property data as personal information.

Sponsor preparation of specific high value propositions for geospatial-centric applications, supported by template business cases. Currently, the opportunity is being missed to increase the pace of adoption and realise the benefits this would unlock. We list below seven key use cases that closely align with Government policy:

1. Understanding patterns of democratic engagement/disengagement - most local authorities hold very detailed demographic data but it is rarely combined with spatial data which could reveal the detail of such patterns.

2. Regeneration of economically disadvantaged areas - spatially enabling inward investment marketing materials and use of 3D models to allow initial evaluation of candidate sites from the developer's desktop.

3. Uncovering poor housing conditions and illegal multiple occupation - highlighting existing best practice using thermal imagery and the role that high resolution 3D city models can play.

4. Building social cohesion and overcoming loneliness - using disaggregated social care data to identify deprived communities at a much more granular level than is possible with census data.

5. Environmental management - clearly articulating how Geospatial supports more effective disaster risk management, air and noise pollution monitoring and climate change mitigation.

6. Supporting development of micro energy generation/grids to identify the best opportunities to increase local adoption of generation from renewable energy sources.

7. Distribute access to technology (e.g. high speed broadband) and its benefits. One strong use case is increasing the use of public street light networks to provide wider low cost access to optical fibre based networks and increased availability of public wifi in city centres.

Build capacity, capability and skills - data aggregation, standardisation, handling and sharing, data science, analytics, consumption - harnessing established centres of expertise e.g. Data Mill North, Worcester Office of Data Analytics, etc.

Invest in existing knowledge sharing networks and platforms - Socitm with its established regional groups, other professional bodies (Solace, CIPFA, RTPI, etc.), Local Government Association, Welsh Local Government Association, Scottish Local Government Improvement Service (Spatial Hub), Scottish Local Government Digital Office, GeoPlace, Knowledge Hub.

Provide hypothecated investment funding, stimulating and building the engagement to enable adoption and adaptation of best practices at the local level. (There have been some successful examples e.g. The Connect Digitally programme – online school admissions and online free school meals that invested in a team of professionals to work with those responsible across England to embed the process and associated technology in their local authorities.)

Q20: How best can we make the UK's presence in the international geospatial world more visible?

Use Socitm's international network – LOLA (the Linked Organisation of Local Authorities), comprising professional associations for the IT, digital and data communities in Australia, Belgium, Canada, Netherlands, New Zealand, Sweden and USA. Further details: http://www.lola-ict.org

Q21: Where should the UK be looking for points of comparison overseas? Who are the other international exemplars? What best practice is being modelled overseas that we can learn from?

Numerous examples of local authorities leading the way exist in parts of Australia, New Zealand and Canada, with applications including forest fire prevention and response, and flood mapping and prevention. Some examples, focusing on the application of drone technology, can be found here: http://www.lgam.info/drone.

Perhaps the most comprehensive example is the work of the Tasmanian Spatial Information Council, whose primary purpose is to "facilitate full access to, and application of, spatial information to underpin Tasmania's economic, environmental and social prosperity".

In terms of promoting data standardisation and sharing, a working example of best practice is the Scottish Local Government Improvement Service's Spatial Hub web portal for the upload, download and consumption of Scottish geospatial data. Individual councils and national park authorities upload various spatial datasets to the Spatial Hub, which are then standardised, merged together and published to create national datasets. This can save local authorities a great deal of time, money and effort in developing their own portals to publish data for their EU INSPIRE directive obligations. Additionally, it provides full and up-to-date national datasets for various public bodies in Scotland, as well as potentially diverting FOI requests away from local authorities.

Geospatial Commission: Call For Evidence Response Questionnaire

Call for evidence - three key themes

We have identified three high-level themes that could help our approach to setting a strategy which are as follows:

1. **Supporting innovation in the geospatial sector**, exploring how to secure cutting edge skills, the right access to data, and opportunities from emerging technologies for the geospatial sector itself
2. **Enhancing the UK's geospatial assets,** looking at how best to align interests, avoid duplication, and instill best practice across the whole public sector
3. **Driving investment and productivity in geospatial applications**, asking in which wider sectors the most value lies from better exploitation and use of geospatial data, in the UK and internationally

Our questions

Q1. Is our view of the geospatial data types accurate? If not, what should be included or excluded from this?

Q2. In addition to current government policy, what are the areas of geospatial skills where the commission could best focus, to help ensure the necessary capability within the UK for the future?

Q3. What are the geospatial skills needs and gaps in your organisations, how can these be most effectively addressed, and how can careers in the sector be best promoted?

Q4. Are there any publicly or privately-held geospatial datasets that are currently challenging to access or use or of insufficient quality, but which you or your organisation would find valuable if these issues could be resolved? Please explain why this would be of value, and how access/quality could be improved?

Open access to the OS AddressBase products would be extremely valuable to Space Syntax, along with many other SME's. The fees currently associated with accessing the products, which start from £130k per annum, are prohibitively expensive for small businesses and are a barrier to growth.

Specifically, the release of the data would enable Space Syntax to create a high value add to our existing consultancy and data services. This is for two reasons; firstly, because it would enable us to structure our data in a highly accessible format, allowing it to be incorporated into BIM Level 3. This would bring an urban context to BIM Level 3, by enabling us to collaborate more effectively and efficiently with a much broader stakeholder base, in the fields of architecture, design and property.

The second is that it enables us to undertake advanced analytics and create integrated models of the urban environment. These models can be use by non-

specialist users and the outputs have been found to correlate with long-term social, economic and environmental outcomes, as well as health and wellbeing outcomes. This therefore extends our client base, as we can sell our products beyond a small field of specialists in planning, as well as potentially provides positive societal benefits.

Q5: Do you anticipate that any changes will be needed to the both address data and the wider address ecosystem, to support emerging technologies? Please provide evidence of value to support any proposed changes.

Q6: How should the commission be looking to develop the UK's capability in Earth observation data, both technologically and to support an effective market?

To have an urban focus, as well as a rural/agricultural focus. As urban focus will benefit multiple professions and support critical social, economic and health outcomes for citizens. It will also help address the need to manage urban expansion and the risks of ecological and environmental damage.

Q7. Which new technologies should the commission focus on to provide new opportunities to process and exploit geospatial data for economic growth?

Q8. How can geospatial data and applications be used to support enhanced roll-out of future technologies?

Q9: What are the options for how public sector organisations could continue to invest in maintaining and enhancing our geospatial data assets?

Q10: What areas of the underpinning geospatial infrastructure such as positioning technologies, including GPS and indoor positioning systems, and geodetic networks and frameworks to support them, should we be prioritising the development of, in order to support the emerging requirements for geospatial data?

Q11: What role should the private sector have in both the development and maintenance of the underpinning infrastructure and enhancing the UK's geospatial data assets?

Q12. Do you face challenges when working with geospatial data from across the public sector? If so, what are they and how could value be better released? Are there any technical remedies or standards that could be adopted to improve the interoperability of geospatial data? Please provide supporting evidence of what these remedies could help to accomplish.

A key challenge that Space Syntax faces when working with geospatial data from across the public sector is related to interoperability. A specific example of this would be the difference between OS (British Coordinate System) coordinates and Google (WGS84) coordinates, which means that combining datasets is problematic, leading to inaccuracies and concerns about the robustness of the datasets. This situation limits our efficiency, addressable markets and scalability, as we have to develop tools for the UK market and tools for the rest of the world.

We would recommend two approaches to help to address this;

Firstly, we would recommend going beyond standards and developing a process of validation prior to the data being released – this could be led by OS. Secondly, we would recommend supporting a range of initiatives such as the current ODI 'Local Government Open Geospatial Data Stimulus Fund' which is designed to grow the public sector's understanding of how to collect, publish and use open geospatial data, with a specific focus on collaborative approaches.

Q13. How can the Geospatial Commission act as a more effective customer for geospatial data on behalf of the public sector?

Q14. Are there any additional geospatial datasets, from the other partner bodies or other sources, that the public sector would derive significant benefit from having access to, that might have novel and valuable use cases? What would that access look like?

Q15: How can we best develop a single UK strategy, ensuring alignment between the individual strategies across the UK while still allowing for regional variations?

Q16: How can we best ensure effective local authority coordination and sharing of best practise, using location data to better deliver public services?

Q17: As a result of this analysis, we are prioritising the exploration of possible initiatives in the high-value categories identified:

- **property and land**
- **infrastructure and construction**
- **mobility**
- **natural resources**
- **sales and marketing**

What are the existing or potential geospatial applications which could be scaled-up or developed in order to capture economic value? (We would particularly welcome responses from industry and other bodies engaged in these sectors.)

There are many excellent geospatial applications across various technology readiness levels (TRLs) which have the potential to capture economic value. However, the first three high-value categories identified are highly contentious, often politically driven, areas of public policy in particular. Therefore, while it is important to consider specific applications which can support decision-making in these areas, it is equally important to understand and analyse the eco-system in which they would operate.

We would recommend that the Geospatial Commission reviews the insights and analysis gained from the Tombolo project, which was conducted using SBRI grant funding over three years and undertaken jointly by Space Syntax and the Future Cities Catapult. http://www.tombolo.org.uk/what-is-tombolo/

This project helped city authorities understand the value of their data and developed a range of products and services in order to support them in this aim, including a *Digital Connector* - an open source piece of software, which allows data specialists to efficiently connect data sets into a common format.

The project gathered a range of insights from city authorities who operated as project partners, into the ways in which different officials and professionals across cities collect, interact with and utilise, data to undertake their roles and deliver services for citizens.

These insights informed the development of the Tombolo products and services, but would provide valuable evidence for the Geospatial Commission in their consideration of initiatives across the high value categories they have identified.

Q18: Are there any other areas that we should look at as a priority?

Q19: What are the main potential private and public sector innovations that will rely on the use of geospatial data to rollout, and are there corresponding regulatory challenges?

Q20: How best can we make the UK's presence in the international geospatial world more visible?

Q21: Where should the UK be looking for points of comparison overseas? Who are the other international exemplars? What best practice is being modelled overseas that we can learn from?

Thank you for your time in completing your response to our call for evidence.

Any questions, please get in touch with the Geospatial Commission via geospatialcommission@cabinetoffice.gov.uk

Geospatial Commission: Call For Evidence Response Questionnaire

Please submit your completed questionnaire to:

geospatialcommission@cabinetoffice.gov.uk.

Clearly title your email *'Call for evidence response'*.

About you and your organisation

Name	[Text Redacted]
Organisation	STFC Hartree Centre
Job title	[Text Redacted]
Address	[Text Redacted]
E-mail	[Text Redacted]
Telephone	[Text Redacted]

Please select which of the following best describes you as a respondent:

Respondent	**Please mark with a X**
Academic	
Business representative / trade body	
Central government	
Charity or social enterprise	
Individual	
Legal representative	
Local government	
Large business (over 250 staff)	
Medium business (50 to 250)	
Small business (10 to 49)	
Micro business (up to 9)	

Other - please state	**Publicly funded research organisation (in collaboration with IBM Research UK)**

Call for evidence - three key themes

We have identified three high-level themes that could help our approach to setting a strategy which are as follows:

1. **Supporting innovation in the geospatial sector**, exploring how to secure cutting edge skills, the right access to data, and opportunities from emerging technologies for the geospatial sector itself
2. **Enhancing the UK's geospatial assets,** looking at how best to align interests, avoid duplication, and instill best practice across the whole public sector
3. **Driving investment and productivity in geospatial applications**, asking in which wider sectors the most value lies from better exploitation and use of geospatial data, in the UK and internationally

Our questions

Q1. Is our view of the geospatial data types accurate? If not, what should be included or excluded from this?

The high-level view is accurate as the definition says that geospatial data is any data that is associated with some spatial information. Some points that could be included to clarify the definition:

- Is indoor data such as building layouts also considered—e.g., airport layouts to better assist travelers OR proximity markers or relevancy measures w.r.t. social data to cluster individuals.
- Geospatial data also requires time identifiers – e.g. single date/time, average over a period, multiple times for the same place.

The definition could be extended to include:

- any data that is in principle attached to a location but is not referenced as such - with some intelligence we might able to understand where a place is.

We note that the definition could be considered overly complex. In the consultation document, the use of "place", "location" and "geospatial data" almost interchangeably is confusing. Examples of each data type would help to clarify the differences.

Q2. In addition to current government policy, what are the areas of geospatial skills where the commission could best focus, to help ensure the necessary capability within the UK for the future?

The paper looks at geospatial skills very much from a "geography" perspective, but it is also important to consider how to approach this from the data science/computing science direction, perhaps providing short professional courses to add geospatial skills to those areas. Probably an online course about "What is geospatial data" could be a good starting point, and some good quality training videos and demos on government infrastructure.

Providing incentives for SMEs and/or larger organisations to upskill their employees on the subject area—be it training their staff (especially low skilled) on professional courses or helping the educational institutes to run specific courses/degrees on the subject area. Though there have been such efforts, sustained funding for such activities has not necessarily continued.

Non-technical users will have different requirements in terms of skills than technical users – e.g. training in using GIS software packages to query existing data versus training in how to integrate live geospatial data into web apps, or more complex 'data wrangling'. Training also needs to be continuous as technology evolves rapidly. For example, one area not well covered is tracking and deriving information from moving objects (e.g. cars, people).

The key is to end fragmentation and setting up standards between organisations and companies, so that everyone is taught similar tools and software so if people switch companies, their skills are transferable.

Q3. What are the geospatial skills needs and gaps in your organisations, how can these be most effectively addressed, and how can careers in the sector be best promoted?

Using vs understanding geospatial data are two different things. Developers of technology which exploits geospatial data will need an in-depth understanding in order to develop novel techniques to efficiently and effectively extract value. For example, given the increasing resolution in geospatial data and real-time decision-making requirements, developers will have to consider different approaches and be able to say that the approach provides some % speedup in the analysis and decision-making process. On top of upskilling staff, the commission could consider running multi-year challenge-driven research programs with clear deliverables of impact in the public or private sector.

Geospatial data skills should not be treated differently to other analysis skills, since people who work with Big Data, do machine learning etc, can easily expand into the geospatial area. At the moment it is restricted as a skill to degrees such

as geoscience, environmental studies, meteorology etc. However with mobile phones and the internet, almost everything these days can have a geotag, so all the Big Data degrees could have a geospatial component integrated so everyone taking these courses have the opportunity to gain the relevant skills.

Q4. Are there any publicly or privately-held geospatial datasets that are currently challenging to access or use or of insufficient quality, but which you or your organisation would find valuable if these issues could be resolved? Please explain why this would be of value, and how access/quality could be improved?

One good way to make access easier would be a national data discovery register. This would make meta data about any data source discoverable so that requirements of people, organisations, and projects could be mapped to the relevant data sets. Some data is always going to be proprietary, but having a mechanism to discover such data through their meta data may enable parties to request access to them for specific purposes. Such a registry would need to be distributed and be based on a platform such as blockchain for transactional guarantees and transparency.

Data access needs to be improved. Different industries will always have different needs, but if data were easily available through a single platform, then access would be straightforward. For example, The Opengov website has a lot of data but all is fragmented and offers links to other websites which contain files, and the licences are not clear. If the Opengov website had just a single access point with clearly defined licences and an easy search tool, all data could be made available i.e. through something like IBM PAIRS (https://www.ibm.com/uk-en/marketplace/geospatial-big-data-analytics) where it's all in one place and also cross data-set queries are allowed.

Licensing existing data under OGL or equivalent open licence is fundamental - we often find potentially useful datasets e.g. from local authorities which would be of great value to commercial customers, but cannot be used for that purpose.

As a specific example, more local authority data (and more consistent data), in the areas of planning and local plans, would be hugely valuable for the construction industry. We are currently working with brownfield registers from local authorities across the country, and although they are supposedly all to the same template, they quality of data is vastly different, and not all are released under the OGL (or it is unclear).

Q5: Do you anticipate that any changes will be needed to the both address data and the wider address ecosystem, to support emerging technologies? Please provide evidence of value to support any proposed changes.

Amore precise method of addressing than postcodes, especially in rural areas, will enable new applications. Postcodes are already inadequate for sat-navs to find properties in rural areas. Something like https://what3words.com/ could work for any non-address location.

Given the uptake in mobile communication protocols (such as 5G) new encoding paradigms may need to be considered as data storage requirements will increase. Given the potential density of a 5G network, one may also consider means to provide inferred geo addresses to data.

Q6: How should the commission be looking to develop the UK's capability in Earth observation data, both technologically and to support an effective market?

Having looked at the potential for using EO data for a project, there still remains a huge challenge in providing "analysis ready" data without losing fidelity e.g. georeferencing images.

Investing in analytics platforms (especially distributed analytics platforms) and supporting projects in this space is needed as the resolution keeps increasing for fine-grained analysis. Also, with the uptake in hyperspectral imagery to better understand environment, this data size will continue to grow. Distributed analytics platforms will be key as transferring data from disparate and distributed data sources for central analysis may not always be possible.

For a platform to be usable, it needs to be scalable and hold (or provide access to) all the data but also offer the capability to analyse the data in-situ and create new datasets. For example, you can use multiple satellite images to get rid of cloud cover but if you want to do that for the whole world, you need large-scale analytics.

Q7. Which new technologies should the commission focus on to provide new opportunities to process and exploit geospatial data for economic growth?

Distributed data discovery platforms and analytics platforms to better exploit data. Such platform should also provide model sharing and value-added data products for cross industry consumption. These should be supported by large compute clusters and include tools like IBM PAIRS which aligns data and makes it easily accessible / queryable.

Q8. How can geospatial data and applications be used to support enhanced roll-out of future technologies?

A pioneering dev-ops platform could be created where the government provides a space for new technologies to be developed (like a startup garage) and then allows exploitation through that platform; it's all about sharing today, no single company, government or system can solve the world's problems, that's why open source is now so popular but large organisations and governments need to provide the platform and space to host this. Some example applications include:

- A single geo-enabled catalogue to easily browse available data. See e.g. https://catalogue.ceh.ac.uk/eidc/documents
- Tools to access multiple pre-processed datasets in a common format while maintaining high spatial and temporal resolution.
- Tools to extract user-relevant data (time and place) from large geospatial datasets
- Real-time data access to constantly updated data sets.

Q9: What are the options for how public sector organisations could continue to invest in maintaining and enhancing our geospatial data assets?

Mainly by adhering to an open standard for data publication and expanding on programs such as open data initiative to expose all geospatial data. Additionally, the transformation of data needs to be transparent and provenance (and associated matrices) of data and processes need to be published.

Having effective business models to incentive organisations to share data is key:

One way to encourage organizations to share data would be a data market place/open innovation platform, where people can share their data for free but have in turn access to other datasets they would usually pay for.

Also service providers could share a small percentage of their profit with the open sector organisation if they use their data to provide services, i.e. per API call or data set access.

Q10: What areas of the underpinning geospatial infrastructure such as positioning technologies, including GPS and indoor positioning systems, and geodetic networks and frameworks to support them, should we be prioritising the development of, in order to support the emerging requirements for geospatial data?

Indoor position systems are key for future business propositions—be it retail (grocery) or people navigation. The current techniques to indoor localization are poor, thus investment in this area has potential high impact.

Q11: What role should the private sector have in both the development and maintenance of the underpinning infrastructure and enhancing the UK's geospatial data assets?

Private sector has a key role to pay not only in development and maintenance of the infrastructure but also on the fundamental research on developing the next generation infrastructure supporting geospatial data. This is mainly because value proposition for a such an infrastructure predominantly lie with existing and emerging private sector organisations—be it logistics or emerging businesses on Internet of Things and Connected and Autonomous Vehicles.

Private companies host the skills and hardware to run these platforms, large tech companies need to be involved as no government or public sector organisation alone will have the skills and expertise to maintain and set up this infrastructure.

Setting up and maintaining an infrastructure is huge challenge and therefore needs to be approached as a large scale IT project - geospatial data is true big data.

Q12. Do you face challenges when working with geospatial data from across the public sector? If so, what are they and how could value be better released? Are there any technical remedies or standards that could be adopted to improve the interoperability of geospatial data? Please provide supporting evidence of what these remedies could help to accomplish.

One challenge with working with data across the public sector is inconsistency in the geospatial identifiers used e.g. for local authority boundaries. In a recent exercise to bring together datasets, some used Ordnance Survey "boundaries_GB" shapefiles, and others used "census" shapefiles, both with different identifiers for the authorities. This increases the amount of manual work, and potentially leads to inconsistencies and errors. A standard approach would be extremely beneficial.

The Opengov website is a good start, but difficult to use in practice - data is available butt very hard to find, the search option is terrible and not clear which datasets are available under which licence, whether there is actually data, what the resolution is and then it is just in single files and not easily downloadable. It could be organised a lot better.

Q13. How can the Geospatial Commission act as a more effective customer for geospatial data on behalf of the public sector?

By creating a single portal from which to access all open data for the public sector, this way it can be monitored and the geospatial commission track which organisations do geospatial data well and have a high buy in and which need to do better.

Q14. Are there any additional geospatial datasets, from the other partner bodies or other sources, that the public sector would derive significant benefit from having access to, that might have novel and valuable use cases? What would that access look like?

Access to British Geological Survey data would allow for interesting research with soil and rock types as an input. Availability of up to date observed weather data (e.g. Met Office UKCP09 project http://catalogue.ceda.ac.uk/uuid/87f43af9d02e42f483351d79b3d6162a, available to 2016) would also allow interesting research, such as some work we did last year looking at driver behaviour.

Open Street Map (https://wiki.openstreetmap.org/wiki/Main_Page)

Q15: How can we best ensure effective local authority coordination and sharing of best practise, using location data to better deliver public services?

More work is needed to roll out consistent templates for data, meta-data and storage to local authorities, and to provide training and/or technological solutions to ensure these are completed consistently (e.g. no text in numeric fields). A suitable forum for sharing best practice across local authorities would also aid consistency.

It is impossible to introduce standards from top down. An alternative bottom up approach is a traffic light system which indicates data quality, i.e. if organisations want to share their data and add to a given platform, then they have to get a "green" first.

Q16: As a result of this analysis, we are prioritising the exploration of possible initiatives in the high-value categories identified:

- **property and land**
- **infrastructure and construction**
- **mobility**
- **natural resources**
- **sales and marketing**

What are the existing or potential geospatial applications which could be scaled-up or developed in order to capture economic value? (We would particularly welcome responses from industry and other bodies engaged in these sectors.)

Some examples based on our experience interacting with businesses at STFC Hartree Centre:

- Property/Land: i.e. Hartree use case for archeology
- Also feeds into construction
- Mobility: IBM/Hartree train delays, smarter traffic management,
- Sales/Marketing: Large supply chain analysis, Food sector
- Natural resources: This must be a key area because of energy and also continuous catastrophic weather events happening more frequently, i.e. name Hartree project for flooding and emergency responses, there is a lot that can be done here,

Q17: Are there any other areas that we should look at as a priority?

To face the current shortage of resources and high demand of services due to an ageing population, healthcare must be a key priority. The use of geolocation (both indoor and outdoor) data provides unprecedented opportunities to monitor patients daily activities remotely, allowing to shift the care paradigm from a reactive to a preventive healthcare system, optimise the use of limited healthcare resources, and understand the risks. This is particularly relevant to aging and mental health, where changes of behaviours are key factors indicating disease worsening/onset.

Q18: What are the main potential private and public sector innovations that will rely on the use of geospatial data to rollout, and are there corresponding regulatory challenges?

Key innovations and applications will come through mobile apps and all the services related to this, e.g. Uber

Q19: How best can we make the UK's presence in the international geospatial world more visible?

Provide a high quality data catalogue/repository - the UK could be the first government in the world who provide all their data through a single portal and provide an open innovation platform, that would be a first and world leading.

Q20: Where should the UK be looking for points of comparison overseas? Who are the other international exemplars? What best practice is being modelled overseas that we can learn from?

Thank you for your time in completing your response to our call for evidence.

Any questions, please get in touch with the Geospatial Commission via geospatialcommission@cabinetoffice.gov.uk

Geospatial Commission: Call For Evidence Response Questionnaire

Response from the Surrey Geospatial and Space Leaders Group –

23 organisations operating in the Space and Geospatial Sector in Surrey

Q1. Is our view of the geospatial data types accurate? If not, what should be included or excluded from this?

It is important to come to a shared understanding on this point. Geospatial data types 1 to 3 are reasonable in our view (note: #1 is recursively defined), although it can be hard to differentiate between type 1 (geospatial data) and type 2 (positional data). The type is sometimes determined by use cases, rather than anything intrinsic to the data. Type 4, Geospatial Services is somewhat ambiguous. Services are usually defined as a method of delivering geospatial data, but the definition seems to imply value-added/derived data. i.e. data that is moved up the value chain towards "geospatial intelligence". Indeed, this may be a better name of type 4 data.

More broadly, we propose that the Geospatial Commission works to establish a comprehensive definition of 'Geospatial' that encompasses its full role and contribution. We suggest;

"The term Geospatial encompasses both earth observation using satellites and other remote vehicles and those activities in data analytics using statistical and geographical frameworks, embracing all the new ways of analysis of the associated data, including those undertaken by machine learning and deep learning.

The resulting geospatial information outputs enable improved decision-making in both the public and private sectors and in both the developed world and the global south, leading to better performance and improved use of resources. Good examples can be found in all economic sectors, including health provision, government, transport, financial services, agriculture, construction and in innovative new services; all of which contribute to both improvements in operational efficiency and wealth creation."

Q2. In addition to current government policy, what are the areas of geospatial skills where the Commission could best focus, to help ensure the necessary capability within the UK for the future?

Developing skills is certainly key and this can be best achieved by promoting geospatial as a career path and better explaining what our industry does, beyond core geography.

If the outcome of the Commission is to release a considerable amount of high-quality data as lower/no cost, it is worth noting that there are currently too few people with the skills to utilise it. It is easy to make bad decisions based on poor use of maps and geospatial data. There are of course, undergraduate degree and master's degree courses available for GIS. There existence reflects the level of sophistication required to use geospatial data effectively and responsibly and therefore the Commission can play a role in encouraging and supporting Universities.

The country should nurture Data Science skills (including mathematics, software engineering, data wrangling and business studies). Geospatial extends this skillset into what some now call "Geodata Science".

Q3. What are the geospatial skills needs and gaps in your organisations, how can these be most effectively addressed, and how can careers in the sector be best promoted?

The geospatial industry has been "sold" quite poorly in the past. There is a real lack of skilled people who understand both the benefits of the industry and how to explain / sell them to a much wider audience. There are important roles for industry organisations (including RGS, AGI, British Cartographic Society, RSPSoc and BARSC) to play in education. Without education, it is unlikely that releasing geospatial data will generate the yield anticipated by the Commission.

Some of the skills needed in the Earth Observation (EO) sector include:

- Geospatial data analysts and data scientists
- Geographical information system (GIS) experts
- Earth observation data analysts and data scientists
- Earth observation data processing engineers
- Programmers with geospatial data processing expertise

Q4. Are there any publicly or privately-held geospatial datasets that are currently challenging to access or use or of insufficient quality, but which you or your organisation would find valuable if these issues could be resolved? Please explain why this would be of value, and how access/quality could be improved?

While the Commission has been focused on data sets such as OS MasterMap, there is arguably greater value in opening addressing in the form of OS AddressBase. There is of course the complication of other parties, including the Royal Mail and Geoplace. This issue aside, many industry professionals believe open addressing will yield a far bigger return to the UK economy than topographic mapping.

The use of common identifiers would help connect data from contrasting sources, including the six organisations identified by the Commission. This work has already started with the introduction of UPRN, but identifiers also need to be open data so that their use is not limited in any practicable way.

In terms of geospatial data, Northern Ireland should not be forgotten as part of the United Kingdom and its data included.

A wealth of "free and open" historical and current Earth Observation satellite data is available worldwide, notably from the European Union's "Copernicus" programme, from the European Space Agency, and from others such as NASA (USA) and JAXA (Japan). There is also a considerable wealth of commercial satellite data available from suppliers based in Europe, North America and Asia.

Tremendous value can be added to geospatial services by combining terrestrial data sources with satellite data sources which provide long time series, consistently acquired data sets with global footprint.

The challenge for the UK is that it lacks a coordinated data access solution that can bring such data sets together and make them easily and operationally accessible to industry for exploitation. The UK has made some attempts (e.g. via the SEDAS hub at the Satellite Applications Catapult, and the JASMIN facility at STFC RAL) but we would strongly prefer to see the UK take a more holistic approach to this.

The Geospatial Commission can play a key role here in coordinating the UK approach to operational access to a rich variety of satellite Earth Observation data sources, alongside access to other

geospatial information sources, for use by government, industry and research communities in the UK.

Q5: Do you anticipate that any changes will be needed to the both address data and the wider address ecosystem, to support emerging technologies? Please provide evidence of value to support any proposed changes.

People will always want more; faster and cheaper access to data will drive innovation. It is unclear whether more access will drive revenue for the data supplier. The release of large-scale topographic data without address data is somewhat meaningless. For example, “Here’s a highly detailed digital representation of a building, but we can’t tell you the associated address(es)!”

BS7666 (The national standard for Addressing) was last formally reviewed and amended in 2006. It would be prudent to undertake a new consultation exercise to address stakeholders with the objective of bringing in scope potential new address types and finalizing the feed of address information from third parties such as the emergency services (previously referred to as the candidate process).

One area that may require adjustment within the address standards is that of the BLPU Level/Height information. Currently this is recorded as a text field and is sparsely populated. With the anticipated growth for drones and associated technology it would be helpful to a have a single definitive height associated with a UPRN.

Q6: How should the Commission be looking to develop the UK’s capability in Earth observation data, both technologically and to support an effective market?

Promoting the British Earth Observation (EO) capabilities should be a simple job as we have a wide range of world-leading skills. Our nation’s EO programme should not only utilise satellite but also use HAPS, conventional aircraft and UAV capabilities.

Open access to as much data as possible, in as simple a use format will have a huge impact on the use of the data and the applications that will subsequently be created. The perfect case-study is how Amazon has promoted Landsat data (which has also worked as a tool to promote its Cloud Services)

A hole exists in the promotion of the British EO industry - something that BARSC, for example, is trying to fill - and work must start on promotion in an informative and exciting way, to draw people towards us. This is a huge opportunity.

The UK Space programme is a major concern for a post-Brexit United Kingdom. We have centres of excellence in Space (e.g. Surrey, Harwell and Glasgow). Any loss of access to key European programmes, including Copernicus and Galileo would be a huge set back. An effective geospatial strategy will need to dovetail perfectly with space-based capabilities.

Unleashing the potential of vast amounts of knowledge and data from satellite earth observation and remote sensing into commercially viable geospatial services is also something addressed within the recent ‘Space Data Revolution’ ISCF Wave 3 submission. This programme aims to create a commercial marketplace for EO data, combining with AI to support useful information services across Energy, Transport, Finance and Construction sectors through collaborative R&D resulting in new platforms, products, services and technologies. Should the SDR programme be successful this should also be considered as an important aspect of academia and industry collaboration to support the geospatial Commission in their strategic objectives. The programme is being led jointly between industry, and the UKRI departments of STFC, NERC and I-UK.

Q7. Which new technologies should the Commission focus on to provide new opportunities to process and exploit geospatial data for economic growth?

The ones that will promote the use of the data, such as Artificial Intelligence. Mass access to data may deliver uses and applications that have not been considered yet (e.g. text messages were only in mobile phones to allow engineers to communicate with each other).

Geospatial and earth observation data is an important input into the UK's expertise in machine vision and AI / Deep Learning. We should like to see a carefully considered strategy from the Commission and not a "make it open and X billion will be added to the UK economy" as a hope-and-prayer. It is questionable as to whether previous rounds of open data had the anticipated benefit and too early to observe whether our European cousins, such as the Netherlands, who have taken an open data approach to their "master level" data have seen a true return. Ensuring that organisations such as Ordnance Survey, and indeed the other key organisations under consideration by the Commission, maintain their high data standards is more important and this can only be done under a long-term funding commitment.

Q8. How can geospatial data and applications be used to support enhanced roll-out of future technologies?

Geospatial data is central to all future technology such as autonomous cars, 5G, clean energy, and augmented reality. For example, nearly every industry now uses SatNav / GNSS in some part of their value chain (even taxi-cabs, where the availability of geospatial data is what enables Uber to disrupt traditional markets). The essential component ensuring Geospatial Data can fulfil this role is that of Standards – for the data itself, interoperability with other datasets, metadata, data sharing and publication. Data and applications have important roles at various phases of the Define/ Develop/ Test/ Rollout/ Deliver lifecycle including;

- Embed (physical/software) spatial awareness in new tech
- De-risking/prototyping algorithms/services against simulated data
- Development of open testbeds of data, tool suites etc.
- Testing the market/focus-groups
- Determine how geospatial data and applications are being used to support enhanced roll-out of current technologies
- End-user/customer engagement to demonstrate comparable, representative systems
- Allows for continuity of data (i.e. roll out of product)
- Allows for reliability of data
- Allows for higher accessibility – know where the data pertaining to a certain region is

They are also of value in supporting emerging technologies, for example;

- Generation of labelled data from existing systems for Machine Learning
- Increase availability and access to Machine learning platforms, e.g. for local council and public use - supporting and monitoring local planning permissions, up-take of solar panels etc and reduce the need for surveyors
- Real time high accuracy spatial monitoring
- Increase availability of geospatial data, especially high-resolution satellite imagery to apply to machine learning – e.g. change detection from imagery e.g. Coastal erosion monitoring – measure rates of erosion and risk factors for use by the insurance sector

- To enable the creation of geospatial data by wider (non-geo) communities, including developing the understanding of the value of such data and the wider impact sharing such data can have
- Enable historic analysis to look at change over time to enhance the use of older data
- Autonomous Vehicles. The systems these use will benefit from accurate surveys: although they will not be reliant on a 3D model they will be able to more quickly compare the environment to expectations. The same may be true for drone / unmanned aerial vehicles
- Building Information Management Systems. These will become a very important technology in the future (coupled with IoT) since they will enable building owners (and government) to better optimize their efficiency and power usage

More generally, opening up datasets for low cost/free use can encourage and enable the development of new concepts that have yet to be defined or even considered in areas including;

- **Tourism**. Asset-tagging of monuments, buildings, artefacts will increase exponentially, either using Near-Field Communication (NFC) or QR codes to provide details on what is being viewed or visited
- **Asset Maintenance**. Locating and reviewing maintenance information about assets will increase. Everything from air conditioning units, to fire extinguishers to bridges and manholes will be mapped (within BIM when relevant) and asset tagged to allow maintenance schedules to be complied with
- **Navigation**. In-car navigation using geo-tech is well established and being enhanced through information about local points of interest. A similar need exists for all walkers, bikers, runners that use information about statutory and non-statutory paths, terrain (ascent/descent) and points of interest to guide them safely around the countryside

Q9: What are the options for how public sector organisations could continue to invest in maintaining and enhancing our geospatial data assets?

The Public Sector should continue to manage, develop and maintain existing publicly available geospatial datasets. It also has a key role in;

- Establishing reciprocal data share agreements with other countries/organisations
- Encouraging and financially incentivising UK commercial entities to provide freely available data sets (with standardised interfaces)
- Incentivising the private sector to contribute data by retaining ownership of data as part of contracts let by the public sector
- Providing financial support to private companies who supply geospatial datasets which have more general applications
- Negotiating to license freely available data sets/subsets (c.f. Planet's Open California initiative) via data access portal with API and data standardisation
- Making data more available within and between public sector organisations through platforms, which can also be shared by the private and third sectors
- Partnering with civil society organisations, industry, academia, individuals and other countries on developing best practice, including standards
- Driving best practice and continuous improvement
- Investing more into organisations like GeoVation supporting new businesses using Location Technologies

- Examining and encouraging agile (spiral development approaches) to data management (e.g. SAFe[1])

Q10: What areas of the underpinning geospatial infrastructure such as positioning technologies, including GPS and indoor positioning systems, and geodetic networks and frameworks to support them, should we be prioritising the development of, in order to support the emerging requirements for geospatial data?

Ensure access to high fidelity GPS service (post Brexit). This includes creating infrastructure and services to defend against the increasing threat of spoofing and jamming the service, both from criminals and terrorists.

Standardising the UK approach on indoor positioning, including;

- Investing in the infrastructure so users' location seamlessly transfers from outside to indoor
- Definition of minimum data quality standards
- Standard agreements on data access, licensing and charging
- Driving the development of the platforms / ability to access indoor geolocation data

Further areas for prioritisation and continued/additional investment include;

- Integration of consumer equipment into network for automatic reporting
- Network wide time synching
- Standard asset categorisation and identification
- Standard metadata formats
- Standardised geodetic networks

Q11: What role should the private sector have in both the development and maintenance of the underpinning infrastructure and enhancing the UK's geospatial data assets?

The Private sector has an equally vital role as does the Public Sector in ensuring it creates, maintains and improves geospatial data assets that are needed by the UK, working in partnership with Government and other sectors to build mutually beneficial solutions. As part of this role it should;

- Work in partnership with government to develop new data quality and interchange/interoperability standards
- Drive the reduction in cost for maintenance and reflect these savings in lowering prices
- Introduce new technologies for maintaining and accessing data sets
- Work in partnership to introduce new data sources using the expertise in industry, specifically around remote sensing/satellite EO, and IoT
- When government uses the private sector to store data with a geospatial component, ensure that it is available through a geospatial data infrastructure
- Contribute updates when suitably qualified as part of 'normal business', particularly when carrying out surveys
- Encourage startups/incubators etc. towards prototyping/piloting systems before full implementation by established suppliers => Agile at pilot and robust at operational
- Provide support for abstraction wrappers over private sector/commercial legacy systems/datasets

[1] SAFe, the Scaled Agile Framework

- The private (and other) sectors should drive the development and commercialisation of the applications and data to the extent that the infrastructure allows

Q12. Do you face challenges when working with geospatial data from across the public sector? If so, what are they and how could value be better released? Are there any technical remedies or standards that could be adopted to improve the interoperability of geospatial data? Please provide supporting evidence of what these remedies could help to accomplish.

From experience we do face multiple challenges, including;

- Knowing what data is available and how to access it
- Whilst a larger number of datasets are available on data.gov.uk, many are difficult to discover, query and process (and the underlying quality is difficult to assess)
- Different formats, syntax, standards, differing levels of accuracy, maintenance regimes and reliability
- Not always in a computer accessible format/media i.e. PDF vs Excel
- Not aware if data is available through an API
- What the licensing requirements are and how long it may take to get a license (i.e. delays in providing authorisation, due to bureaucracy)
- Constraints to usage that discourage accessing/ using it
- Different set of access/usage for constraints for every dataset

Remedies include;

- Suggest going with a REST interface with Single Sign-on (SSO)
- Introduce simplified geospatial platforms
- Provide Analysis Ready Data (ARD)
- Simplified and Standardised licensing arrangements
- Development/improvement of an international standard like INSPIRE that fulfils the majority of user needs
- Providing clarity and certainty on data quality, availability and freshness making it easier for the private sector to invest in solutions knowing that the underlying data will be available in the future
- MOU's/cooperative agreements between organisations to allow for the development of data and solutions, both over the short and longer term. These agreements could lead to the development of (public and private and third sector) groups that share the cost of data collection or generation (e.g. MoD's Multinational Mapping Co-production Programme)

Regarding the Ordnance Survey specifically, whose data (including OS MasterMap level mapping) represents the gold standard of mapping globally, the issues are;

- Its cost is precluding its use more widely
- As the maintenance schedule is insufficient / uncertain / inconsistent, additional topographic surveys have to be conducted by consultants on behalf of the public sector. These surveys are not shared or managed in a way that allows their re-use. This leads to huge waste when surveys are repeated in the same area

Remedies, which would be hugely beneficial to the UK and save considerable amounts of public sector cost include;

- Reducing the cost of OS products, and/or

- Developing a repository for ALL topographic and aerial imagery data collected and paid for on behalf of the Public Sector for reuse by the Public Sector and if the original contractual conditions allowed, reuse by the private sector

Q13. How can the Geospatial Commission act as a more effective customer for geospatial data on behalf of the public sector?

We see the real value of the Geospatial Commission flowing from it being more than an effective customer for the Public Sector. If its role included enabling other sectors to gain access to Public sector data, support and encourage private sector innovation and was to engage with others to create the wider systems of sharing and collaboration between Public sector and elsewhere, then it would fulfil a truly effective role in the Geospatial ecosystem. To achieve this we see it needing to;

- Fully understand user needs – from private companies in the sector, to government departments
- Understand what data needs to be kept public (not privatised)
- Pool requirements and purchasing (acquire once, use many times enabled by a joined-up IT infrastructure)
- Engage with industry providing a focal point for exchanging problems and solutions. Coordinate and communicate status, needs, solutions, innovations and research across all input and output stakeholders
- Develop a Geospatial Innovation Programme enabling an evidence and experimental approach to data release, quality and access
- Act as a common procurement entity
- Apply common standards (this can help exports)
- Give a clearer sense of strategy to industry to help it develop the next generation of tools
- Help companies sell geospatial solutions overseas by developing the relationship through the Department of International Trade and the international programmes of UKRI
- Understand what data needs constant updating
- Standardise data requirements, format, access mechanisms
- Drive innovation - e.g. workshops
- Define data abstraction mechanisms
- Know what current best practice and state of the art is, then look to see what future systems can bring, so ordering the best product at the best price

The Commission could procure data for the public sector in the knowledge that when it becomes open and available to private sector, there will be opportunities for UK private sector to commercially exploit it.

Q14. Are there any additional geospatial datasets, from the other partner bodies or other sources, that the public sector would derive significant benefit from having access to, that might have novel and valuable use cases? What would that access look like?

There are many! The duplication of efforts around data creation and development are staggering, both within and between public sector organisations but with the other sectors as well. The re-use and repurposing of collected and processed data is significantly under developed. Ideas include;

(It may be that some of these listed here are already available and we aren't aware of it, that some are partially available and that others are available but not in easily usable formats or on suitable licensing terms)

- Census findings
- Electoral info
- Air Quality
- Metadata of all available state-provisioned sensors
- Public mobile data – anonymised e.g. accelerometer, GPS & mast tower data
- Social media aggregator
- Public mobile photos – useful in disaster scenarios
- AIS/ADS-B Streams
- Supporting metadata for dynamic data streams e.g. ship MMSI catalogues
- DEFRA/EA data streams (i.e. Environmental Data Exchange portal by the Digital Catapult)
- Open Street Map – use metadata to provide store of government/council resources e.g. libraries, toilets, health services etc.
- Utility companies' services/data feeds
- Rail and Bus companies' services/data feeds
- Road network traffic and camera data
- Post Office & national geocoder and reverse geocoder
- National gazetteer (multilingual)
- Solar Panel Systems locations/capacity/performance
- CCTV
- Regular / fresh EO imagery including VHR and 1m class SAR coverage of the UK (can use used for change detection)
- Adequate access to Copernicus data needs to be secured post-Brexit
- Non-classified imagery acquired by the MOD shared across government

There is also an issue with the ability of the Public Sector to accept or use Geospatial Data that has been collected and generated by private sector firms, on behalf of the Government, for analysis purposes.

Broader collaboration, outside of established contracts, through MoUs, Collaborative agreements, communities of interest would also be of assistance.

Regarding access – the same issues and remedies listed in our answers to Question 12 apply.

Q15: How can we best develop a single UK strategy, ensuring alignment between the individual strategies across the UK while still allowing for national variations?

It would seem sensible to work with what already exists, rather than starting completely afresh, therefore taking a co-ordinated approach to the strategy, with each DA creating their own around an agreed central spine seems appropriate. There are however certain components that should be centrally agreed, to ensure compatible access to data across the whole of Great Britain and NI (and indeed the other jurisdictions such as the Channel Islands and the Isle of Man). These include;

- Common Standards (using existing International standards) for data, metadata and services associated with access to the data
- Common data formats, themes, feature definitions

- Shared and consistent access platforms – not centralised repositories, but a Clearing House or data catalogue concept
- Pricing and licensing – a common strategy covering the whole of the Great Britain and NI, so making it easier and simpler to obtain and use data
- Common Governance process for updating and changing the above over time

Q16: How can we best ensure effective local authority coordination and sharing of best practise, using location data to better deliver public services?

To help ensure coordination and sharing of best practice among local authorities, the Geospatial Commission could establish some key themes that would attract participation and representation from the local authorities. In collaborative discussions and meetings, the local authorities often identify collective issues and solutions. Unfortunately, the local authorities are under resourced and therefore the Geospatial Commission will need to have those key themes to ensure engagement with others regarding their geospatial priorities.

The benefits of having a formal standard for recording and sharing this information can be seen by the impact of introducing BS7666, the national standard for addressing in GB. This has enabled the proliferation of multiple solutions that conform to this to be generated and supplied to the public sector. It has helped form a truly competitive market place and not a fabricated one dominated by monopolies.

Organisations large and small have built innovative solutions that drive down costs and improve efficiencies. The adherence to a standard also means a public sector organisation is not dependent on one solution/supplier. This is essential for competition to work. If a better solution is available, this can be adopted without compromising the whole operation of the organisation. A common standard for location intelligence information described above can have the same catalytic effect, benefiting public safety without overburdening the tax payer.

Q17: As a result of this analysis, we are prioritising the exploration of possible initiatives in the high-value categories identified:

- **property and land**
- **infrastructure and construction**
- **mobility**
- **natural resources**
- **sales and marketing**

What are the existing or potential geospatial applications which could be scaled-up or developed in order to capture economic value? (We would particularly welcome responses from industry and other bodies engaged in these sectors.)

There are many innovations in the public and private sector that have a geospatial element, and we can anticipate many more in the future. These include healthcare and social services for aging populations, connecting geospatial content to the internet of things technology, routing and transport for goods and people, or services for the financial sector.

As a specific example, there is no common dataset across the country which captures what is on the road. For example, speed limits, parking restrictions, crossing points etc. This is likely to become more important with the introduction of autonomous vehicles.

Q18: Are there any other areas that we should look at as a priority?

We should like to see remote sensing and Earth Observation represented as a priority area for geospatial within the Geospatial Commission. As data analytics and applications integrate satellite, UAV and other data, we would like the Geospatial Commission to ensure that it is capturing this capability as part of the geospatial story. Given the cross government uses of remote sensing, we've never achieved a solid UK strategy for this capability – the Geospatial Commission is uniquely positioned to take some leadership responsibility and help achieve better development and procurement of such services by the public sector.

One area that has been discussed before is the opening up of address data and remove the IP barriers that exist when using this dataset. It is widely accepted that the address data has significant importance and value to the economy. Not only does it serve to act as the foundation for service provision throughout the public and private sector, it is one geospatial dataset that is widely recognised by the public.

According to the white paper issued by the Open Addresses project (https://www.scribd.com/document/265440465/Open-Addresses-the-story-so-far#download)

"A 2012 report from the PAF Advisory Board estimated its value to the UK economy to be between £992m - £1.32bn each year. In 2002, the Danish Government made its national address file available for free. Since then it has calculated its direct financial benefits to cost ratio at 30 to 1. By 2010, the year in which their report was published, they estimated the direct benefits of free address data to the Danish population to be around EUR 14m, with costs of EUR 0.2m. Scaling to the UK population, this would be an annual benefit of around £110m. In their 2014 report for the Department of Business, Innovation & Skills, Katalysis recognised the need for Open National Address dataset: "UK society relies heavily on address data and current products have helped greatly to create benefit. The review has determined that Open usage would result in substantial and valuable growth among new user types and with even greater community benefit. The recommendation is that a basic address product should be free to all users at the point of use."

Another area in which work could be implemented to help ensure value from geospatial datasets available is to centralize and improve the accuracy of a national data catalog or ClearingHouse. In many situations a dataset may already exist, collated and maintained by an organization but it may not be readily apparent to a potential consumer of that data. A national data catalog referencing the existence, license type, accuracy, provenance, metadata of datasets would help increase the utilization of datasets throughout the UK.

As data analytics and applications that integrate satellite, drones, high altitude platforms and other data emerge and evolve, along with complementing big data technologies like artificial intelligence and machine learning, the Geospatial Commission should ensure that these vital capabilities (in which the UK has excellent heritage) are clearly adopted and exploited as part of the national geospatial strategy.

Q19: What are the main potential private and public sector innovations that will rely on the use of geospatial data to rollout, and are there corresponding regulatory challenges?

There are countless public and private sector innovations that have a geospatial element, and we can anticipate many more in the future. These include healthcare and social services for aging populations, connecting geospatial content to the internet of things technology, routing and transport for goods and people, or services for the financial sector.

Some of these innovations will have particular regulatory challenges that will need to be addressed, however, at this stage we need to work on the regulatory challenges of the data feeds themselves. For example, we need to see more open data that enables geospatial innovations and the UK government needs to establish its regulatory framework for how Earth Observation data from UK satellites can be distributed commercially.

Q20: How best can we make the UK's presence in the international geospatial world more visible?

Establishing the Geospatial Commission is an excellent first step for demonstrating the UK's presence internationally.

The UK has a very sophisticated and, despite the many issues, a very efficient geospatial ecosystem. We take many things for granted because of our geospatial heritage. The benefits from this experience simply do not exist in most countries in the world. The UK has the standards, technology and business processes to support geospatial use in both the public and private sectors. This can become a huge revenue source for the country if deployed across the world.

The contributors to this ecosystem are many, they vary considerably in size and international presence. Currently each contributor has to make their own efforts to reach out to the international market. This effort is considerable and often prohibitively so for most. It is also often completely uncoordinated. The benefits of systems, standards and processes that work seamlessly together is often lost when looked at in isolation. Given the huge logistical issues with doing business abroad it will be very useful to work in a more coordinated fashion with government assistance where necessary.

A geospatial sector specific initiative that promotes an overall business solution abroad and sponsored by the government would be very useful. The focus should be on overall solutions to business / economic issues helped by geospatial solutions rather than the technology. This can be set up and coordinated by leaders in the geospatial industry. This should be focused at specific countries where current initiatives are being planned. We need the DIT people on the ground to be briefed on the things to look for and highlight them early so early intervention by geospatial experts can take place. There also needs to be an emphasis on solutions that deliver benefit rather just strategies that a nation can adopt.

This coordinated approach with the help of the government can help realise currently untapped geospatial potential in the UK.

Q21: Where should the UK be looking for points of comparison overseas? Who are the other international exemplars? What best practice is being modelled overseas that we can learn from?

There are several examples. Australia in particular is progressing highly effectively through the leadership of Geoscience Australia, an organisation that is implementing best practice and joining up effectively with new capability. The Nordics and the Netherlands have approaches that are worth looking at. China and South Korea are known to be doing a lot in this area, however information is limited.

Mexico is an innovator in this field – it has established an over-arching organisation organisation called INEGI to manage all geospatial information for the country.

Beyond consideration of best practice in public sector delivery of geospatial, we should consider best practice in the private sector and identify areas where we can better integrate advances in the private sector. With their extensive membership, the OGC could provide an excellent service here for ensuring an efficient and joined up approach with commercial capabilities.

Geospatial Commission: Call For Evidence Response Questionnaire

Please submit your completed questionnaire to:

geospatialcommission@cabinetoffice.gov.uk.

Clearly title your email *'Call for evidence response'*.

About you and your organisation

Name	[Text Redacted]
Organisation	Surrey Satellite Technology Ltd
Job title	[Text Redacted]
Address	[Text Redacted]
E-mail	[Text Redacted]
Telephone	[Text Redacted]

Please select which of the following best describes you as a respondent:

Respondent	Please mark with a X
Academic	
Business representative / trade body	
Central government	
Charity or social enterprise	
Individual	
Legal representative	
Local government	
Large business (over 250 staff)	**X**
Medium business (50 to 250)	
Small business (10 to 49)	

Micro business (up to 9)	
Other - please state	

Call for evidence - three key themes

We have identified three high-level themes that could help our approach to setting a strategy which are as follows:

1. **Supporting innovation in the geospatial sector**, exploring how to secure cutting edge skills, the right access to data, and opportunities from emerging technologies for the geospatial sector itself
2. **Enhancing the UK's geospatial assets,** looking at how best to align interests, avoid duplication, and instill best practice across the whole public sector
3. **Driving investment and productivity in geospatial applications**, asking in which wider sectors the most value lies from better exploitation and use of geospatial data, in the UK and internationally

Our questions

Q1. Is our view of the geospatial data types accurate? If not, what should be included or excluded from this?

Q2. In addition to current government policy, what are the areas of geospatial skills where the commission could best focus, to help ensure the necessary capability within the UK for the future?

- Remote sensing - understanding of capability and performance of sensors and interpretation of resulting imagery/data
- Image processing/data science – manipulation of, and extraction of information from, Earth observation and geospatial data
- Statistical skills – extracting meaningful trends from geospatial information

Q3. What are the geospatial skills needs and gaps in your organisations, how can these be most effectively addressed, and how can careers in the sector be best promoted?

Skill gaps:
- Remote Sensing - understanding of capability and performance of Earth observation sensors and interpretation of resulting imagery/data
- Image processing/data science – manipulation of, and extraction of information from, Earth observation and geospatial data

How can these be addressed:
- Recruitment from relevant graduate and post-graduate courses
- Specific training
- Collaboration with academia/other experts
- Wider education of available careers in the geospatial sector

Q4. Are there any publicly or privately-held geospatial datasets that are currently challenging to access or use or of insufficient quality, but which you or your organisation would find valuable if these issues could be resolved? Please explain why this would be of value, and how access/quality could be improved?

Datasets e.g.
- Global satellite AIS/ADS-B
- Land cover/land use data
- Meteorological records – e.g. cloud cover, rainfall
- Dynamic traffic information

Although some of this information is available, historical data is not always accessible and the format is not always useful – e.g. bitmaps and PDFs rather than data that can be manipulated

Q5: Do you anticipate that any changes will be needed to the both address data and the wider address ecosystem, to support emerging technologies? Please provide evidence of value to support any proposed changes.

Q6: How should the commission be looking to develop the UK's capability in Earth observation data, both technologically and to support an effective market?

SSTL recommends that the UK develops its sovereign Earth Observation capability, either to complement the Sentinel data or to ensure access to Sentinel-equivalent data following Brexit (if Copernicus open access policy reconsidered in future). Current gaps in Sentinel offerings:

- High temporal resolution - this could be achieved through a sovereign constellation of small satellites
- High fidelity, high resolution optical imagery
- High fidelity, high resolution SAR imagery – to complement NovaSAR
- Non optical – AIS/ADS-B
- Super/Hyper-spectral imagery
- HAPS/UAVS for continuous monitoring of key areas of interest

Provide access to data through hub which delivers analysis ready data (i.e. pre-processing already performed – e.g. atmospheric, geospatial correction)

Increase global UK ground station network – e.g. sovereign territories – to improve timeliness

Q7. Which new technologies should the commission focus on to provide new opportunities to process and exploit geospatial data for economic growth?

Nationwide comms network (5G/WiFi) – to enable delivery of data/information from location – e.g. remote monitoring stations

On-board operations/autonomy

Inter Satellite comms (LEO-GEO-GS, intra-constellation – to enable rapid satellite tasking and data dissemination)

Q8. How can geospatial data and applications be used to support enhanced roll-out of future technologies?

Potential use of existing data:

- De-risking/prototyping algorithms/services against simulated data
- Generation of labelled data from existing systems for Machine Learning
- End-user/customer engagement to demonstrate comparable, representative systems
- Testing the market/focus-groups
- Open up older archive data for low cost/free use
- Development of open testbeds of data, tool suites etc.

Q9: What are the options for how public sector organisations could continue to invest in maintaining and enhancing our geospatial data assets?

Potential options for public sector involvement:

- Reciprocal data share agreements with other countries/organisations
- Encouragement/incentivisation of UK commercial entities to provide freely available data sets (with standardised interfaces)
- Freely available data sets/subsets (c.f. Planet's Open California initiative) via data access portal with API and data standardisation

Q10: What areas of the underpinning geospatial infrastructure such as positioning technologies, including GPS and indoor positioning systems, and geodetic networks and frameworks to support them, should we be prioritising the development of, in order to support the emerging requirements for geospatial data?

Priority geospatial infrastructure:

- Ensure access to high fidelity GPS service (post Brexit)
- Standardising UK approach on indoor positioning
- Definition of minimum data quality standards
- Standard agreements on data access, licensing and charging
- Reliable city and country wide comms networks (WiFi/IOT/LoraWAN/5G networks) for access to available data/information
- Integration of consumer equipment into network for automatic reporting
- Network wide time synching
- Standard asset categorisation and identification
- Standard metadata format
- Standard geospatial reference frameworks

Q11: What role should the private sector have in both the development and maintenance of the underpinning infrastructure and enhancing the UK's geospatial data assets?

Incentives (e.g. tax breaks/grants) to encourage release/utilisation of private sector/commercial assets and data into infrastructure

Encourage startups/incubators etc. towards prototyping/piloting systems before full implementation by established suppliers => Agile at pilot and robust at operational

Support for abstraction wrappers over private sector/commercial legacy systems/datasets

Q12. Do you face challenges when working with geospatial data from across the public sector? If so, what are they and how could value be better released? Are there any technical remedies or standards that could be adopted to improve the interoperability of geospatial data? Please provide supporting evidence of what these remedies could help to accomplish.

Challenges in using geospatial data

- Knowing what data is available and how to access it
- Different formats & syntax
- Not always in a computer accessible format/media i.e. PDF vs Excel
- Not always available through an API?
- Licensing and timeliness (i.e. delay to provide authorisation due to bureaucracy) constraints to access
- constraints to usage that discourage accessing/ using it
- Different sets of access/usage for constraints for every data set
- Accuracy, level of maintenance and reliability unknown?

Potential remedies

- Suggest going with a REST interface with Single Sign-on (SSO)
- Provision of Analysis Ready Data
- Simplified and Standardised licensing arrangements
- Standard access mechanisms

Q13. How can the Geospatial Commission act as a more effective customer for geospatial data on behalf of the public sector?

Standardise data requirements, format, access mechanisms

Drive innovation - e.g. workshops

Coordinate and communicate status, needs, solutions, innovations and research across all input and output stakeholders

Define abstraction mechanisms

Provide education on availability and use of datasets

Q14. Are there any additional geospatial datasets, from the other partner bodies or other sources, that the public sector would derive significant benefit from having access to, that might have novel and valuable use cases? What would that access look like?

Additional datasets of benefit:

- Regular EO imagery including high resolution optical and SAR coverage of the UK
- Adequate access to Copernicus data post-Brexit
- Census findings
- Electoral info
- Air Quality
- Metadata of all available state-provisioned sensors
- Public mobile data – anonymised e.g. accelerometer, GPS & mast tower data
- Social media aggregator
- Public mobile photos – useful in disaster scenarios
- AIS/ADS-B Streams
- Supporting metadata for dynamic data streams e.g. ship MMSI catalogues
- DEFRA/EA data streams (i.e. Environmental Data Exchange portal by the Digital Catapult)
- Open Street Map – use metadata to provide store of government/council resources e.g. libraries, toilets, health services etc.
- Utility companies' services/data feeds
- Rail and Bus companies' services/data feeds
- Road network traffic and camera data
- Post Office & national geocoder and reverse geocoder
- National gazetteer (multilingual)
- Solar Panel Systems locations/capacity/performance
- CCTV

Q15: How can we best ensure effective local authority coordination and sharing of best practise, using location data to better deliver public services?

Q16: As a result of this analysis, we are prioritising the exploration of possible initiatives in the high-value categories identified:

- **property and land**
- **infrastructure and construction**
- **mobility**
- **natural resources**
- **sales and marketing**

What are the existing or potential geospatial applications which could be scaled-up or developed in order to capture economic value? (We would particularly welcome responses from industry and other bodies engaged in these sectors.)

Q17: Are there any other areas that we should look at as a priority?

Earth Observation – ensuring the UK has access to existing datasets (e.g. Copernicus) now and in the future and developing a strategy for providing access to new and enhanced datasets in the future.

Q18: What are the main potential private and public sector innovations that will rely on the use of geospatial data to rollout, and are there corresponding regulatory challenges?

A UK Earth Observation Data Policy is urgently required to govern, for example, export restrictions associated with imagery data, to facilitate commercial activities of satellite manufacturers and data providers.

Sales opportunities for SSTL have been lost because of the lack of this policy.

Q19: How best can we make the UK's presence in the international geospatial world more visible?

Q20: Where should the UK be looking for points of comparison overseas? Who are the other international exemplars? What best practice is being modelled overseas that we can learn from?

Thank you for your time in completing your response to our call for evidence.

Any questions, please get in touch with the Geospatial Commission via geospatialcommission@cabinetoffice.gov.uk

Geospatial Commission: Call For Evidence Response Questionnaire

Please submit your completed questionnaire to:

geospatialcommission@cabinetoffice.gov.uk.

Clearly title your email *'Call for evidence response'*.

About you and your organisation

Name	[Text Redacted]
Organisation	Survey4BIM
Job title	[Text Redacted]
Address	[Text Redacted]
E-mail	[Text Redacted]
Telephone	[Text Redacted]

Please select which of the following best describes you as a respondent:

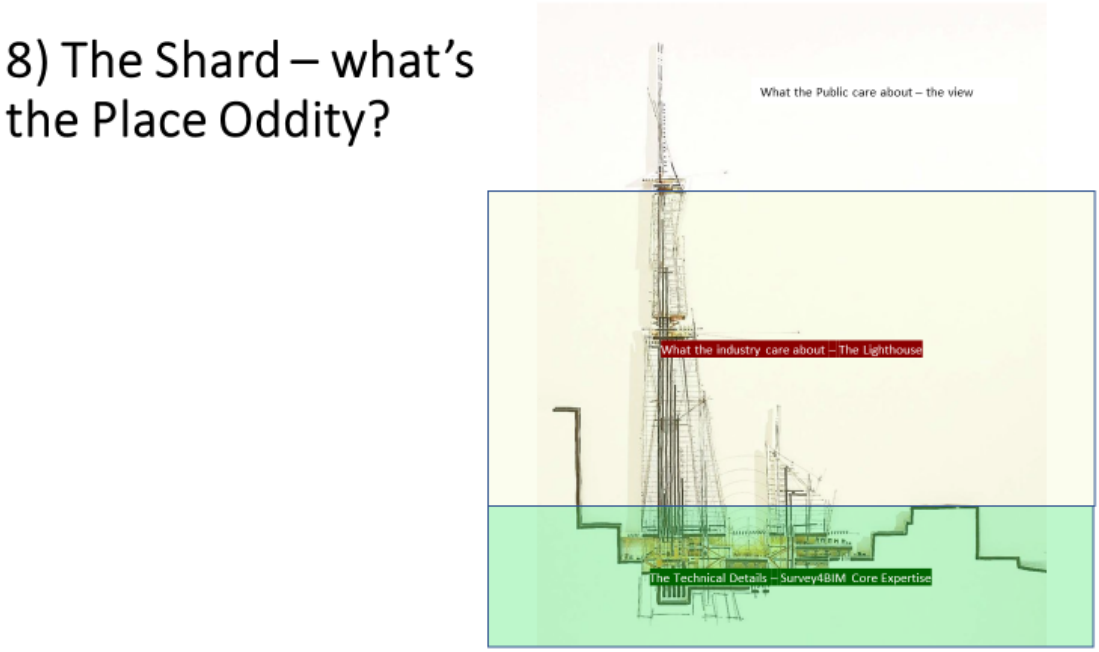
Respondent	**Please mark with a X**
Academic	
Business representative / trade body	
Central government	
Charity or social enterprise	
Individual	
Legal representative	
Local government	
Large business (over 250 staff)	
Medium business (50 to 250)	
Small business (10 to 49)	
Micro business (up to 9)	

Other - please state	**Professional Working Group**

The survey industry is a small industry with few people wearing many hats. With this in mind we endorse and do not want to repeat the input you have received from the Chartered Institution of Civil Engineering Surveyors.

However, we would like to add that we want to ensure that there are some basic principles that we would want followed with the use of Geospatial data – that is primarily – **People First.** We are in favour of Smart Cities, of which the foundation is Geospatial, but we are acutely aware that we run the risk of getting lost in the detail and over focused on technology for technologies sake.

With that in mind, I would like to explain the following slide from one of our recent engagement presentations.



The aim of Survey4BIM is to deal and talk in "Space & Time". After all everything comes down to particles and how they change over time. The clever part is understanding relationships between particles, analyzing how they change and enabling infrastructure to respond accordingly to ensure that smart buildings, that make up smart cities, work for the population.

To make this clear – The public care about the view from the top of the Shard, they care about how amazingly fast the lifts are and that they work 100%, they might care to know that even on the top floor there is a public convenience (that they do not have access to).

Survey4BIM's industry peers care about the structure the enables the public to use the facility, and that everything fits together, and functions as designed. They should care about a digital twin to modernize their Facilities Management capabilities.

Survey4BIM are totally focused on putting the shard in the right place, maintaining that place information over time and keeping that base map information up to date and timely.

After all, it's all location, location, location!

And so, I hope this helps explain why I will not fill in the answers to rest of the questions, as the answer to all questions is do the right thing, **people first.**

[Text Redacted]

Call for evidence - three key themes

We have identified three high-level themes that could help our approach to setting a strategy which are as follows:

1. **Supporting innovation in the geospatial sector**, exploring how to secure cutting edge skills, the right access to data, and opportunities from emerging technologies for the geospatial sector itself
2. **Enhancing the UK's geospatial assets,** looking at how best to align interests, avoid duplication, and instill best practice across the whole public sector
3. **Driving investment and productivity in geospatial applications**, asking in which wider sectors the most value lies from better exploitation and use of geospatial data, in the UK and internationally

Our questions

Q1. Is our view of the geospatial data types accurate? If not, what should be included or excluded from this?

Q2. In addition to current government policy, what are the areas of geospatial skills where the commission could best focus, to help ensure the necessary capability within the UK for the future?

Q3. What are the geospatial skills needs and gaps in your organisations, how can these be most effectively addressed, and how can careers in the sector be best promoted?

Q4. Are there any publicly or privately-held geospatial datasets that are currently challenging to access or use or of insufficient quality, but which you or your organisation would find valuable if these issues could be resolved? Please explain why this would be of value, and how access/quality could be improved?

Q5: Do you anticipate that any changes will be needed to the both address data and the wider address ecosystem, to support emerging technologies? Please provide evidence of value to support any proposed changes.

Q6: How should the commission be looking to develop the UK's capability in Earth observation data, both technologically and to support an effective market?

Q7. Which new technologies should the commission focus on to provide new opportunities to process and exploit geospatial data for economic growth?

Q8. How can geospatial data and applications be used to support enhanced roll-out of future technologies?

Q9: What are the options for how public sector organisations could continue to invest in maintaining and enhancing our geospatial data assets?

Q10: What areas of the underpinning geospatial infrastructure such as positioning technologies, including GPS and indoor positioning systems, and geodetic networks and frameworks to support them, should we be prioritising the development of, in order to support the emerging requirements for geospatial data?

Q11: What role should the private sector have in both the development and maintenance of the underpinning infrastructure and enhancing the UK's geospatial data assets?

Q12. Do you face challenges when working with geospatial data from across the public sector? If so, what are they and how could value be better released?

Are there any technical remedies or standards that could be adopted to improve the interoperability of geospatial data? Please provide supporting evidence of what these remedies could help to accomplish.

Q13. How can the Geospatial Commission act as a more effective customer for geospatial data on behalf of the public sector?

Q14. Are there any additional geospatial datasets, from the other partner bodies or other sources, that the public sector would derive significant benefit from having access to, that might have novel and valuable use cases? What would that access look like?

Q15: How can we best develop a single UK strategy, ensuring alignment between the individual strategies across the UK while still allwoing for regional variations?

Q16: How can we best ensure effective local authority coordination and sharing of best practise, using location data to better deliver public services?

Q17: As a result of this analysis, we are prioritising the exploration of possible initiatives in the high-value categories identified:

- **property and land**
- **infrastructure and construction**
- **mobility**
- **natural resources**
- **sales and marketing**

What are the existing or potential geospatial applications which could be scaled-up or developed in order to capture economic value? (We would particularly welcome responses from industry and other bodies engaged in these sectors.)

Q18: Are there any other areas that we should look at as a priority?

Q19: What are the main potential private and public sector innovations that will rely on the use of geospatial data to rollout, and are there corresponding regulatory challenges?

Q20: How best can we make the UK's presence in the international geospatial world more visible?

Q21: Where should the UK be looking for points of comparison overseas? Who are the other international exemplars? What best practice is being modelled overseas that we can learn from?

Thank you for your time in completing your response to our call for evidence.

Any questions, please get in touch with the Geospatial Commission via geospatialcommission@cabinetoffice.gov.uk

Geospatial Commission: Call For Evidence Response Questionnaire

Please submit your completed questionnaire to:

geospatialcommission@cabinetoffice.gov.uk.

Clearly title your email *'Call for evidence response'*.

About you and your organisation

Name	[Text Redacted]
Organisation	Survey4BIM
Job title	[Text Redacted]
Address	[Text Redacted]
E-mail	[Text Redacted]
Telephone	[Text Redacted]

Please select which of the following best describes you as a respondent:

Respondent	**Please mark with a X**
Academic	
Business representative / trade body	
Central government	
Charity or social enterprise	
Individual	
Legal representative	
Local government	
Large business (over 250 staff)	
Medium business (50 to 250)	
Small business (10 to 49)	
Micro business (up to 9)	

Other - please state	**Professional Working Group**

We would like to emphasise that the use of public geospatial data is primarily to empower p**eople first.**

We are in favour of Smart Cities, of which the foundation we believe is a Geospatial Digital Twin. But we are acutely aware that we run the risk of getting lost in the corporate exploitation of data over the societal ownership and benefits of wider context national geospatial mapping and a digital twin could bring. We believe the Geospatial Commission can play a leading role in ensuring the UK brings the benefits of geospatial data to all its citizens. As such our responses represent a wide spectrum of geospatial professionals who care about the profession and its contribution. We support in parallel the submission by the RICS and ICES but believe as an open forum of volunteers who are interested in the success of the geospatial profession in society we can offer some unique and insightful contributions to your call to evidence and goals.

Yours sincerely
Survey4BIM Committee

Survey4bim.wordpress.com

Call for evidence - three key themes

We have identified three high-level themes that could help our approach to setting a strategy which are as follows:

1. **Supporting innovation in the geospatial sector**, exploring how to secure cutting edge skills, the right access to data, and opportunities from emerging technologies for the geospatial sector itself
2. **Enhancing the UK's geospatial assets,** looking at how best to align interests, avoid duplication, and instill best practice across the whole public sector
3. **Driving investment and productivity in geospatial applications**, asking in which wider sectors the most value lies from better exploitation and use of geospatial data, in the UK and internationally

Our questions

Q1. Is our view of the geospatial data types accurate? If not, what should be included or excluded from this?

We suggest you should add Geospatial platforms
- like Google maps - the platforms that allow geospatial data to be visualized and interpreted and added to with the content of users who may offer their services. Google offers this with formats such as KMZ and commercial services. The UK geospatial commission could provide a more innovative and accessible platform for more precise UK datasets

Q2. In addition to current government policy, what are the areas of geospatial skills where the commission could best focus, to help ensure the necessary capability within the UK for the future?

The Professions and professional competency across core spatial professions (Remote Sensing, Land, Hydrographic and Engineering Surveying) and related professions (Geography , Computing, Logistics, Architecture, Planning, Building, Environmental Science) being enhanced, reinforced and upgraded for a digital age.

Q3. What are the geospatial skills needs and gaps in your organisations, how can these be most effectively addressed, and how can careers in the sector be best promoted?

Lack of professional recognition within organization for Information Management and Geospatial Leads,

Many large organisations these leads are completely missing - passed to related Engineering groups not specialised in geospatial skills, or just completely ignored with lack of lessons learnt or complete gaps in spatial awareness and accuracy of information. Organisations such as Network Rail have no head of Geospatial Data although they collect and use vast quantities of such data.

Q4. Are there any publicly or privately-held geospatial datasets that are currently challenging to access or use or of insufficient quality, but which you or your organisation would find valuable if these issues could be resolved? Please explain why this would be of value, and how access/quality could be improved?

OS master map, Utility Records and Land registry offer the greatest base value for building a platform for future capability and services analysis as well as a market for continuous update and improvement of geo-spatial data sets.

At many different levels these three datasets provide the backdrop for reviewing resource and investment needs and outcomes for many businesses and social services and policies - they fundamental form the basis of a national digital twin, spatial strategy and platform for smart infrastructure and policy / decision making, as well as public accountability and transparency for resource allocation

Q5: Do you anticipate that any changes will be needed to the both address data and the wider address ecosystem, to support emerging technologies? Please provide evidence of value to support any proposed changes.

Certainly - increasing services transactions and users are interested in their people and dynamic asset point locations - not static object point locations.
With the exception of coordinates (which are difficult to use as none specialists) there are limited ways to point locate, thus limiting interaction and exchange - referencing systems like What Three Words eliminate the risks posed by wide area or non-specific location referencing (i.e. streets which are very long and lack physical building numbers, post codes which are geospatially too large (up to 80km2) and risk mis-location (as happened in the Olympic Park with a heart attack victim and Ambulance miscommunication).
Equally organisations may like to overlay their own asset location systems (like Railway Engineer Line References and mileages) to assist access and inventory management of key assets and supply chain / stakeholder engagement. So summary organisations should be allowed to add new ones

Q6: How should the commission be looking to develop the UK's capability in Earth observation data, both technologically and to support an effective market?

This relates to platforms and data originating coding (so it's source organisation can be traced and credited with sharing (or royalty payments9. The UK needs data repositories and tools to share and disseminate data via controlled platforms and traceability of capturer.

Secondly the UK needs to understand that there are 2 digital Twins - A Capacity Model (design and theoretical) and a Performance model (reality / as-built). The former is very structured, logical and defined by discrete elements and activities / functionality which are intended and detailed (i.e. roads and junctions, buildings and service networks) the later is continually changing and required for discrete change measurement or aggregation (car movements , earth movements , water flooding etc, distortion of man made and natural resources and assets).
The short term storage capacity needs to be high volume, but long term can be substantially lower based on change / aggregation analysis (i.e. the difference to the capacity model)
It is the rapid processing, dissemination and analysis of geospatial data that represents the real challenge - not the static storage - this can be solved by automation and inexpensive storage systems for retrieval , archive and replacement with updates

Q7. Which new technologies should the commission focus on to provide new opportunities to process and exploit geospatial data for economic growth?

Platform technologies and data dissemination and sharing
Processing technologies
Data transformation tools (grids, formats , metadata standards)
Visualisation and spatial analysis tools

Q8. How can geospatial data and applications be used to support enhanced roll-out of future technologies?

Sensor miniaturization and accuracy improvement via increased spatial reference systems infrastructure and communications (continuous, integrity based, augmented systems such as cameras, Wi-Fi, internal, GNSS network densification (Galileo) and on the fly ad-hic networks (phone, IOT, scada, vehicle sensors) for indoor and urban canyon scenarios

Q9: What are the options for how public sector organisations could continue to invest in maintaining and enhancing our geospatial data assets?

Provide national supported / mandated datasets (i.e. EA flood mapping, OS maps, Land Registry Maps),
Allow commercial partnerships and export capability freedom for organisations providing public mapping
Preferential treatment for Innovation funding and hub / training provision (like the Geovation Hub in London or conferences and open engagement events,
Tax breaks/ recovery for sharing data with public bodies,
Block chain data organization tracking for licensing / royalty recovery over certain use / purposes - i.e. like technology recovery licensing and royalty arrangements for mobile phones and computers or the music industry

Q10: What areas of the underpinning geospatial infrastructure such as positioning technologies, including GPS and indoor positioning systems, and geodetic networks and frameworks to support them, should we be prioritising the development of, in order to support the emerging requirements for geospatial data?

OS CORRS, Satellite and Cartesian reference frame verification - densified in cities and non-open sky areas will support geospatial use
 - increased wifi and 4/5 G availability
- Platform hosting technologies for large geospatial datasets and data marts

Q11: What role should the private sector have in both the development and maintenance of the underpinning infrastructure and enhancing the UK's geospatial data assets?

Private sector engagement should start with franchised utilities and infrastructure businesses who should support a Smart Infrastructure model and upgrade their systems to provide 3D digital data and logic for their systems geospatially – private sector bodies who already enjoy public asset of market sector dominance via franchise.

The commissioned should include trade body SME representation and professional body representation , along with major stakeholder organisations

Academic institutes and innovation centres should be supported with preferential access, even if privately owned – subject to data originator traceability and recovery

Q12. Do you face challenges when working with geospatial data from across the public sector? If so, what are they and how could value be better released? Are there any technical remedies or standards that could be adopted to improve the interoperability of geospatial data? Please provide supporting evidence of what these remedies could help to accomplish.

Firstly the release of data in digital formats which are directly consumable in geospatial systems (objects / vectors),
Secondly the 3D management of data (2D is extremely limiting),
Thirdly the reference frame conversion of data needs to be accurate (ETRS89 Cartesian is the core requirement for single point location, coupled with accuracy value attributes) and tools for this need to be support for smaller firms and innovators in service provision (so they don't distort geospatial referencing

Q13. How can the Geospatial Commission act as a more effective customer for geospatial data on behalf of the public sector?

Register and manage partners and provide blockchain licensing codes,
Be responsible for advising government on public sector bodies, and public sector issued franchise utility and services license (wifi),
Own the digital twin geospatial model for the state and maintain a platform for access, sharing and innovation for all interested and registered partners (in collaboration with the strategic government agencies
Market UK Geospatial Showcases world wide

Q14. Are there any additional geospatial datasets, from the other partner bodies or other sources, that the public sector would derive significant benefit

from having access to, that might have novel and valuable use cases? What would that access look like?

Services, Utilities and Transport Infrastructure models are key overlays for a smart infrastructure model and capacity models.

Parks and public services asset models could also add significant value.

Q15: How can we best develop a single UK strategy, ensuring alignment between the individual strategies across the UK while still allowing for regional variations?

Base content can be agreed, but user overlays can vary significantly by regions , as well as partnership and innovation initiatives.
Agreed common access sharing and pricing for large organisation sharing and use of their datasets if added to the portal (based on regional agreements on publications – regions deciding what can go on the publicly accessible data platform
Agreed security protocols with sensible risk appetite based on already accessible datasets (i.e. google maps / earth)

Q16: How can we best ensure effective local authority coordination and sharing of best practise, using location data to better deliver public services?

LIst all organisations geospatial datasets ownership and set accessibility partner levels and pricing recovery models
Provide reports and case study on benefits and returns, and user access and sharing by dataset and organisation
Allow user feedback on data quality and benefits / issues

Q17: As a result of this analysis, we are prioritising the exploration of possible initiatives in the high-value categories identified:

- **property and land**
- **infrastructure and construction**
- **mobility**
- **natural resources**

- **sales and marketing**

What are the existing or potential geospatial applications which could be scaled-up or developed in order to capture economic value? (We would particularly welcome responses from industry and other bodies engaged in these sectors.)

Capability model for people (safety, sales, crowd mapping, concerts), vehicle (work, private and public) and utilities and transport networks

Q18: Are there any other areas that we should look at as a priority?

Utility models - power, sewer, water, telecoms

3D upgrade of Land Reg and OS data
Addition of recognised accuracy attribute
Creation of geospatial platform for digital twin
Tools for grid conversion and registration of data originators and sharers
Wifi and wired reference frame infrastructure

Q19: What are the main potential private and public sector innovations that will rely on the use of geospatial data to rollout, and are there corresponding regulatory challenges?

Web based location services,
Asset management tools - businesses modelling their assets and capability
Social resources and planning tools - local authority and investment tools
Utilities and franchises services data sharing requirements and capacity modelling
Risk modelling and resilience

Q20: How best can we make the UK's presence in the international geospatial world more visible?

Create a UK digital twin and the platform / ecosystem to control sharing, innovate and commercialisation geospatial data for capability, capacity and future prediction of social and economic activities

Q21: Where should the UK be looking for points of comparison overseas? Who are the other international exemplars? What best practice is being modelled overseas that we can learn from?

Google Earth and Maps
Dutch Land registry Model,
New Istanbul Integrated City Model
Singapore transport model
Munich and Toronto City Models

Thank you for your time in completing your response to our call for evidence.

Call for evidence - three key themes

We have identified three high-level themes that could help our approach to setting a strategy which are as follows:

1. **Supporting innovation in the geospatial sector**, exploring how to secure cutting edge skills, the right access to data, and opportunities from emerging technologies for the geospatial sector itself
2. **Enhancing the UK's geospatial assets,** looking at how best to align interests, avoid duplication, and instill best practice across the whole public sector
3. **Driving investment and productivity in geospatial applications**, asking in which wider sectors the most value lies from better exploitation and use of geospatial data, in the UK and internationally

Our questions

Q18: Are there any other areas that we should look at as a priority?

It's exciting to hear that the UK government is to proactively support and fund innovation within the geospatial sector. An opportunity to shape new futures, solve both environmental and public problems and create new markets. An opportunity to harness human creativity across communities and countries.

My brief consultation contribution will focus on the benefits of taking a new 'whole system' and 'triple bottom line' approach to geospatial data to facilitate the co-creation of community wellbeing.

By a 'whole system' approach I mean that by combining and publishing place-based data sets across different themes, citizens can get a much more comprehensive view of their local neighbourhood, and by a 'triple bottom line' approach I mean the opportunity to deliver every place-based intervention, product or service maximising social, environmental and economic growth.

New approaches to location data and (totally accessible) information will need to be facilitated by a new standards framework for near real time comparisons on different interventions in different geographies - and the sharing of good practice within a new culture of transparent peer-based learning, experimentation and continuous innovation.

The world's leading climate scientists have warned us that there is only twelve years for global warming to be kept to a maximum of 1.5C, beyond which even half a degree will significantly worsen the risks of drought, floods, extreme heat and poverty for hundreds of millions of people. And as we know our urgent social challenges also cover mental health, inequality, obesity, loneliness and aging societies.

For the first time in 15 years the UK government has released a new Civil Society Strategy with a strapline of "People, Place, Partnership" advocating a new culture of cross sector collaboration within 'places'. Place leaders will need comprehensive location information as part of their operating toolkit as they work on the necessary institutional and individual behaviour changes within a new devolved collaborative culture. With both data transparency and accessibility key to improving productivity.

So, in summary a new proactive and holistic focus on geospatial data is exciting because it has the potential to support place-based creativity, co-ordination and co-operation for change – growth that is outcome focussed, smart and inclusive.

Geospatial Commission: Call For Evidence Response Questionnaire

Please submit your completed questionnaire to:

geospatialcommission@cabinetoffice.gov.uk.

Clearly title your email *'Call for evidence response'*.

About you and your organisation

Call for evidence - three key themes

We have identified three high-level themes that could help our approach to setting a strategy which are as follows:

1. **Supporting innovation in the geospatial sector**, exploring how to secure cutting edge skills, the right access to data, and opportunities from emerging technologies for the geospatial sector itself
2. **Enhancing the UK's geospatial assets,** looking at how best to align interests, avoid duplication, and instill best practice across the whole public sector
3. **Driving investment and productivity in geospatial applications**, asking in which wider sectors the most value lies from better exploitation and use of geospatial data, in the UK and internationally

Our questions

Q1. Is our view of the geospatial data types accurate? If not, what should be included or excluded from this?

There is a large focus upon economic growth, however the environmental potential is wide ranging. Flood prevention, pollution, monitoring of protected species such as bats and monitoring landslide risk are all areas well suited to geospatial data.

Q2. In addition to current government policy, what are the areas of geospatial skills where the commission could best focus, to help ensure the necessary capability within the UK for the future?

Regulation and training for the use of UAV equipment should be promoted more strongly.

In addition, software technology to process these large datasets needs to be fostered.

Q3. What are the geospatial skills needs and gaps in your organisations, how can these be most effectively addressed, and how can careers in the sector be best promoted?

As mentioned in Q2, the use of UAVs is currently not well understood by either hobbyists or the industry. Responsible use and better understanding of how to capture quality data need to be promoted. British companies creating the equipment and processing technologies should also be stimulated.

Q4. Are there any publicly or privately-held geospatial datasets that are currently challenging to access or use or of insufficient quality, but which you or your organisation would find valuable if these issues could be resolved? Please explain why this would be of value, and how access/quality could be improved?

In England and Wales, LIDAR (laser-based topographic surveys) are currently freely available via the Environment Agency. This data is patchy at best, and is not available at all in Scotland due to poorly planned copyright reasons. It is essential that the dataset be bolstered and made more freely available. An example of where this would be effectively used would be in flood prevention and flood risk assessment.

Q5: Do you anticipate that any changes will be needed to the both address data and the wider address ecosystem, to support emerging technologies? Please provide evidence of value to support any proposed changes.

Question unclear.

Q6: How should the commission be looking to develop the UK's capability in Earth observation data, both technologically and to support an effective market?

Continued contribution to the European space agency and access to the Galileo programme are essential for the UK to further our capability. These issues of science should not be as highly politicised.

Q7. Which new technologies should the commission focus on to provide new opportunities to process and exploit geospatial data for economic growth?

Ground and UAV based photogrametry and orthophotography, as well as LiDAR technology are advancing very rapidly. They are becoming more detailed and accurate.

Q8. How can geospatial data and applications be used to support enhanced roll-out of future technologies?

Automation (whether of automobiles, agricultural equipment, or military, will rely upon an accurate baseline geospatial dataset.

Q9: What are the options for how public sector organisations could continue to invest in maintaining and enhancing our geospatial data assets?

As mentioned in Q4, controlling copyright of any data gathered for the public sector is essential to foster its wider use.

Q10: What areas of the underpinning geospatial infrastructure such as positioning technologies, including GPS and indoor positioning systems, and geodetic networks and frameworks to support them, should we be prioritising the development of, in order to support the emerging requirements for geospatial data?

Continued contribution to the European space agency and access to the Galileo programme.

Q11: What role should the private sector have in both the development and maintenance of the underpinning infrastructure and enhancing the UK's geospatial data assets?

Data should be shared wherever possible. For example, the British Geological Survey already runs a system where data can be sent to them for curation and sharing on platforms such as iGeology. This is largely in place for sub-surface data at present, but the approach should be taken for surficial and aerial data also.

Q12. Do you face challenges when working with geospatial data from across the public sector? If so, what are they and how could value be better released? Are there any technical remedies or standards that could be adopted to improve the interoperability of geospatial data? Please provide supporting evidence of what these remedies could help to accomplish.

See answer to Q4.

Q13. How can the Geospatial Commission act as a more effective customer for geospatial data on behalf of the public sector?

Publicity is key. Indeed, I myself only heard about this call for evidence at a conference.

Q14. Are there any additional geospatial datasets, from the other partner bodies or other sources, that the public sector would derive significant benefit

from having access to, that might have novel and valuable use cases? What would that access look like?

http://mapapps.bgs.ac.uk/geologyofbritain/home.html

An HTML5 viewer (which can be used on almost any computer or smartphone) is an effective format. The example above is very effective. Geological data on the whole UK. There is also an AR app displaying the same data.

Another example is the Environment Agency flood risk data portal.

Q15: How can we best develop a single UK strategy, ensuring alignment between the individual strategies across the UK while still allwoing for regional variations?

The question itself is something of a paradox. This approach lead to the issue explained in the answer to Q4. I do not believe that there is a practical need for regional variation when it comes to scientific data.

Q16: How can we best ensure effective local authority coordination and sharing of best practise, using location data to better deliver public services?

Better alignment of other systems, outside of geospatial data, would help to foster this. Subjectively, however, cross-regional training of public servants to try and get them to the same level of expertise when it comes to geospatial data would be a good start.

Q17: As a result of this analysis, we are prioritising the exploration of possible initiatives in the high-value categories identified:

- **property and land**
- **infrastructure and construction**
- **mobility**
- **natural resources**

- **sales and marketing**

What are the existing or potential geospatial applications which could be scaled-up or developed in order to capture economic value? (We would particularly welcome responses from industry and other bodies engaged in these sectors.)

GIS applications as a means of displaying, analysing and sharing geospatial data would be an effective vehicle for many of these topics. In tarmac, for example. We run a “Land Information System”. This is a GIS which contains company ownership boundaries, planning information, documents, local authority boundaries, geological information, etc. Any data can be pulled together in such a system, as long as it has coordinates. Effective collation and curatorship of geospatial data will ensure that it is more widely used.

Q18: Are there any other areas that we should look at as a priority?

The UK mineral planning strategy.

Q19: What are the main potential private and public sector innovations that will rely on the use of geospatial data to rollout, and are there corresponding regulatory challenges?

See answer to Q8.

Q20: How best can we make the UK's presence in the international geospatial world more visible?

With contributions to international initiatives, such as Horizon 2020 and its successors, the European space agency, access to the Galileo and educational programmes such as Erasmus.

Q21: Where should the UK be looking for points of comparison overseas? Who are the other international exemplars? What best practice is being modelled overseas that we can learn from?

https://what3words.com/partner/mongol-post/

Thank you for your time in completing your response to our call for evidence.

Call for evidence - three key themes

We have identified three high-level themes that could help our approach to setting a strategy which are as follows:

1. **Supporting innovation in the geospatial sector**, exploring how to secure cutting edge skills, the right access to data, and opportunities from emerging technologies for the geospatial sector itself
2. **Enhancing the UK's geospatial assets,** looking at how best to align interests, avoid duplication, and instill best practice across the whole public sector
3. **Driving investment and productivity in geospatial applications**, asking in which wider sectors the most value lies from better exploitation and use of geospatial data, in the UK and internationally

Our questions

Q1. Is our view of the geospatial data types accurate? If not, what should be included or excluded from this?

We agree but would recommend that the "Positional data" should be considered Thematic Data, with its positional information given by the geospatial identifier. For example crime statistics for a ward are Thematic data, and the positional information of the ward given by the geospatial identifier.

Q2. In addition to current government policy, what are the areas of geospatial skills where the commission could best focus, to help ensure the necessary capability within the UK for the future?

Key themes such as open data, security of data, data quality assurance, data standards and privacy. These issues are enablers to growth in the geospatial data sector

The make up of UK's Geospatial and Earth Observation specialist resource pool is cosmopolitan. It would not be surprising to find the UK with a Brexit-related skills shortages in the short term. Ensuring that Geographic Information and Data Science skills are highly positioned in any future home office immigration strategy would be welcomed.

Positioning (i.e. navigation) competence is poorly represented and poorly supported nationally compared with competing states. For all mobility applications and for many infrastructure & construction applications, the positioning and movement of vehicles and assets is vital. UK government should consider strengthening both governmental and UK industrial relative weakness in positioning technology, or risk foreign competition securing the majority of industrial growth in mobility (land vehicle, autonomous vehicle, RPAS, aircraft, shipping) applications and services.

Q3. What are the geospatial skills needs and gaps in your organisations, how can these be most effectively addressed, and how can careers in the sector be best promoted?

Cabinet could ensure that the Home Office prioritises Geospatial, Earth Observation, GNSS and positioning specialists as part of any post-Brexit immigration policy.

As new technologies become ever more commonplace, it is essential to ensure that the students have a broad enough education such that candidates for employment could more often have both geospatial and AI/machine learning knowledge. There should not be situations where an geospatial organisation has to choose to employ an AI or geospatial focused candidate for lack of both skills in one person.

Q4. Are there any publicly or privately-held geospatial datasets that are currently challenging to access or use or of insufficient quality, but which you or your organisation would find valuable if these issues could be resolved? Please explain why this would be of value, and how access/quality could be improved?

Cabinet Office could lead the charge with discoverable APIs of publicly-held datasets and shift the focus away from data downloads and/or portal (WebGIS) viewers.

Further examples of data that could be made available for the public good are data that are held by NERC/universities for academic use. A specific example encountered by the author was access to Level1-3 of the NERC British Isles

continuous GNSS Facility GNSS observations data which at the time of writing is accessible only by academics. Entities in the private sector can only access lower level data which needs specialist software to make the data useful for geospatial applications.

Q5: Do you anticipate that any changes will be needed to the both address data and the wider address ecosystem, to support emerging technologies? Please provide evidence of value to support any proposed changes.

Reverse address lookup (from geographic location to address/postcode) would be particularly useful for AI technologies which are identifying behaviours on geographic locations and wanting to tag the behaviour change detected to addresses.

Q6: How should the commission be looking to develop the UK's capability in Earth observation data, both technologically and to support an effective market?

The commission should align with the approach taken in the UKspace sector bid and Industrial Strategy Challenge Fund proposal (data refinery). Further to this, the advantages of near real time data should be maximised leveraging upon existing investments made such as the COSMO-SkyMed User Terminal for NRT data access.

Q7. Which new technologies should the commission focus on to provide new opportunities to process and exploit geospatial data for economic growth?

Deep Learning approaches applied to distributed multiple sources of geospatial data. Access to computing resource via cloud computing is now at a level where previously unforeseen geospatial co-analysis of an entire nation's geospatial data is possible.

Positioning and guidance technologies, route optimisation, integrity and robustness of positioning for critical applications are essential technological elements in the exploitation geospatial data.

It should also be noted that pace of development is such that legislation needs also to evolve at the same pace to navigate and guide the trends and interactions between technology and people with respect to: blockchains, gig economy, IoT and their inherent spatial constituents.

Q8. How can geospatial data and applications be used to support enhanced roll-out of future technologies?

Remote monitoring operational services through combined Earth Observation platforms, software, analytics and IT infrastructure. These may provide automated alerts for technical specialists to appropriately triage, react to and guide subsequent human interventions in areas where human "boots on the ground" surveys are the only method available at present.
Future applications of VR/AR/immersive technology could build novel applications based upon the use and translation of multiple geospatial data – existing "baseline" data with NRT analytics.

Q9: What are the options for how public sector organisations could continue to invest in maintaining and enhancing our geospatial data assets?

Funding is a key issue, and taking on new investment on an organisation by organisation basis is very difficult. However, there are fundamental datasets, especially ones derived from satellite analytics that would have multi-agency benefits. A concept of subscription by the organisations to efficiently fund the maintenance and new national datasets would reduce the overall cost to Government, reduce silos and reduce duplication of effort/procurement.

Q10: What areas of the underpinning geospatial infrastructure such as positioning technologies, including GPS and indoor positioning systems, and geodetic networks and frameworks to support them, should we be prioritising

the development of, in order to support the emerging requirements for geospatial data?

It is essential that the UK stays in the EU space programmes Copernicus and Galileo.
“Downstream” positioning technologies including GNSS, Indoor beacons & technologies, Inertial systems, and machine vision technologies are crucial elements. The integration of these technologies is immature for most markets and will bring substantial benefits to performance as well as robustness against threats. “Downstream” technologies are the engines of economic growth, and in turn depend on investments in “Upstream” State-funded systems like GPS, Galileo, and perhaps UK GNSS.

Q11: What role should the private sector have in both the development and maintenance of the underpinning infrastructure and enhancing the UK’s geospatial data assets?

The private sector are experts in this field and should be the go-to with respect to fulfilment of government infrastructures that underpin geospatial services. Having this approach will also allow further benefits to be realised to the UK economy, as entrusting this to industry would mean that the UK industrial capability would be further developed and the approaches/solutions employed would have significant export potential to those countries with lower geospatial readiness.

Q12. Do you face challenges when working with geospatial data from across the public sector? If so, what are they and how could value be better released? Are there any technical remedies or standards that could be adopted to improve the interoperability of geospatial data? Please provide supporting evidence of what these remedies could help to accomplish.

Adopting existing standards (OGC, BSI or otherwise) that serves a wide cross-sectoral need, publish to it, expand it if required, and publish the extensions with a standards agency to allow other public and private bodies to mirror use of the updated standard. This will help ensure that metadata is complete and the data ready to use, without the need to contact the dataset’s originator for further guidance.

Q13. How can the Geospatial Commission act as a more effective customer for geospatial data on behalf of the public sector?

The Geospatial Commission could encourage the public sector partners to align around a common strategy. It could also act as a requirement broker and match multi-agency needs against effective country-wide data set and capabilities available from industry. Also in reverse, by having a good understanding of the industry capabilities across broad data themes, it should be able to help connect the benefits of such data purchases to the maximum number of public sector users.

Q14. Are there any additional geospatial datasets, from the other partner bodies or other sources, that the public sector would derive significant benefit from having access to, that might have novel and valuable use cases? What would that access look like?

The Rural Payments Agency collects a variety of satellite and aerial imagery to support its activity in the efficient payments of farming and rural payments. The classification datasets and indeed the underlying imagery could have significant value for planning, local government and other environmental management functions.

Q15: How can we best develop a single UK strategy, ensuring alignment between the individual strategies across the UK while still allwoing for regional variations?

The Commission needs to have the resources to enable its partners to work together. Creating new collaborations and initiatives does not come free and many similar initiatives have failed in the past due to lack of government funding and a lack of willingness to change organisational structures. Regional variations in priority will determine the activities ongoing and planned next, but the commission could capture the longer term strategy of each region as well as elements that could be added when taking a whole UK approach.

Q16: How can we best ensure effective local authority coordination and sharing of best practise, using location data to better deliver public services?

From the devolved administrations to local authority level the commission could establish a network of lead geospatial practitioners and their identified thematic application areas and utilise modern communication methods to hold on-line best practice sharing activities for the network of practitioners focused on the same thematic. A geospatial commission lead per thematic could develop the experiences shown into a national best-practice on-line resource to allow learnings of disparate groups to be shared and easily accessed.

Q17: As a result of this analysis, we are prioritising the exploration of possible initiatives in the high-value categories identified:

- **property and land**
- **infrastructure and construction**
- **mobility**
- **natural resources**
- **sales and marketing**

What are the existing or potential geospatial applications which could be scaled-up or developed in order to capture economic value? (We would particularly welcome responses from industry and other bodies engaged in these sectors.)

The benefits of using remote monitoring techniques from satellite, aircraft and drone for major infrastructure projects has been proven and could become an industry standard requirement. The extensive image archives that exist across the UK means EO data can provide monitoring services for pre, during and post construction. Datasets such as ground deformation, monthly ground cover change, flood mapping would have application to many of the identified categories (property and land, infrastructure and construction, natural resources).

Q18: Are there any other areas that we should look at as a priority?

EO services to the Maritime sector are relatively mature compared to other sectors and include:

- Ship tracking using satellite AIS and Synthetic Aperture Radar (SAR). Used for monitoring activity around sensitive sites and for combating illegal fishing
- Oil spill detection using SAR – a service that is used by the European Maritime Safety Agency

Emergency and Natural Disaster Response. EO data provides up to date information on flooding, landslides, storm damage and other events that impact on the environment. Having a UK ground station infrastructure offers the capability to receive satellite data in near real time and provide fit for purpose services to the first responder community.

Q19: What are the main potential private and public sector innovations that will rely on the use of geospatial data to rollout, and are there corresponding regulatory challenges?

Persuading industries to adopt new services that utilise EO data requires a level of trust to be built in the technology, and proof that concepts work and regulatory standards have been met. Examples include services that monitor Critical National Infrastructure assets in sectors such as transport and energy.

In the case of transport, and rail in particular, “Moving block signalling” as a replacement for “fixed-block” has the potential to increase rail capacity by 50% on exiting rail infrastructure. Rail regulation and standardisation is notoriously complex and slow, and Governmental support to unblock regulatory blocks would be helpful.

Q20: How best can we make the UK’s presence in the international geospatial world more visible?

The commission should encourage international collaboration and inter government agreements to share data (for example from national EO missions).

Whilst geospatial data (UK government's traditional focus) is developed and maintained nationally, positioning systems that use and exploit that data are international. Successful industries that provide positioning technologies, applications and services are all international. Deeper governmental support for development of positioning technologies would be a powerful engine for growth and international engagement.

Q21: Where should the UK be looking for points of comparison overseas? Who are the other international exemplars? What best practice is being modelled overseas that we can learn from?

A starting point is the Digital Economy and Society Index https://ec.europa.eu/digital-single-market/en/desi. This suggests Denmark, Sweden, Finland, and the Netherlands have the most advanced digital economies in the EU and lessons could be learned from these countries.
The US are clear leaders in GNSS technologies, and many other positioning technologies too. The US has also led the world on providing open access to dataset collected for the public good. Belgium are an exemplar European state to have significantly benefited from investments in the Galileo system in terms of creating downstream businesses fit for economic growth and exploitation.

Thank you for your time in completing your response to our call for evidence.

Any questions, please get in touch with the Geospatial Commission via geospatialcommission@cabinetoffice.gov.uk

Geospatial Commission: Call For Evidence Response Questionnaire

Please submit your completed questionnaire to:

geospatialcommission@cabinetoffice.gov.uk.

Medium business (50 to 250)	
Small business (10 to 49)	X
Micro business (up to 9)	
Other - please state	

Call for evidence - three key themes

We have identified three high-level themes that could help our approach to setting a strategy which are as follows:

1. **Supporting innovation in the geospatial sector**, exploring how to secure cutting edge skills, the right access to data, and opportunities from emerging technologies for the geospatial sector itself
2. **Enhancing the UK's geospatial assets,** looking at how best to align interests, avoid duplication, and instill best practice across the whole public sector
3. **Driving investment and productivity in geospatial applications**, asking in which wider sectors the most value lies from better exploitation and use of geospatial data, in the UK and internationally

Our questions

Q1. Is our view of the geospatial data types accurate? If not, what should be included or excluded from this?

Yes, I agree with the general principles.

Q2. In addition to current government policy, what are the areas of geospatial skills where the commission could best focus, to help ensure the necessary capability within the UK for the future?

Focus on physical-to-digital data capture techniques: Digitisation of hard copy archive material into GIS. Investment in and exposure of machine learning to help achieve this.

Streamlining/combining various addressing datasets into a single offering.

Q3. What are the geospatial skills needs and gaps in your organisations, how can these be most effectively addressed, and how can careers in the sector be best promoted?

We currently have in-house GIS expertise but as above, we'd like to possess the skills to enable machine-learning and map recognition techniques. Through government driven digitisation programs that employ these techniques, we could access or purchase the end product instead.

Q4. Are there any publicly or privately-held geospatial datasets that are currently challenging to access or use or of insufficient quality, but which you or your organisation would find valuable if these issues could be resolved? Please explain why this would be of value, and how access/quality could be improved?

Digitised historic mapping archives held by OS and the BGS would be of great value to us. There exists hundreds of OS maps from the 19th and early 20th century which contain extensive geospatial information. When these features (such as mine shafts, wells, coal seams) are recognised and converted to GIS format, a Historic Landuse Database (HLUD) is created.

Armed with an HLUD, we could realise the full extent of mining history across the UK and assign appropriate risk ratings to properties without manually interpreting historic maps.

The OS licence a small number of commercial organisations to sub-licence access to the historic maps. Through this route, the cost of a map pack for a given site can run into hundreds of pounds – a prohibitive cost. We believe OS should release an HLUD as a competitively priced product, or at least open access to the maps.

Q5: Do you anticipate that any changes will be needed to the both address data and the wider address ecosystem, to support emerging technologies? Please provide evidence of value to support any proposed changes.

Our problem with address data is the sheer size of the databases causing issues with processing in GIS and querying. We'd like a slimmed down version of AddressBase offered to tackle these performance issues.

Additionally, the file format of OS AddressBase is incredibly inconvenient and unpopular. The .gml file format can only be accessed using licensed (paid) ESRI software or PostGIS enabled QGIS plugins. For ease of access going forward, any addressing product needs to be supplied in ‘GIS ready’ File Geodatabases.

Q6: How should the commission be looking to develop the UK's capability in Earth observation data, both technologically and to support an effective market?

We have existing partnerships with high tech satellite processing companies and have enjoyed that relationship. If the commission were to set up a repository of free to access ground deformation/observation datasets for the private sector, it could enable smaller companies to further innovation.

Q7. Which new technologies should the commission focus on to provide new opportunities to process and exploit geospatial data for economic growth?

-machine learning (automatic geo-referencing and digitisation of features on physical or digital maps.)
-Augmented reality (for viewing assets and hidden earth hazards from a first-person perspective)

Q8. How can geospatial data and applications be used to support enhanced roll-out of future technologies?

-public facing, interactive maps (?)

Q9: What are the options for how public sector organisations could continue to invest in maintaining and enhancing our geospatial data assets?

-commercialising and licensing out their datasets. Forming partnerships with the private sector.

Q10: What areas of the underpinning geospatial infrastructure such as positioning technologies, including GPS and indoor positioning systems, and geodetic networks and frameworks to support them, should we be prioritising the development of, in order to support the emerging requirements for geospatial data?

-making sure geospatial standards are met, requiring coordinate metadata to be included in every geospatial asset.

Q11: What role should the private sector have in both the development and maintenance of the underpinning infrastructure and enhancing the UK's geospatial data assets?

-the private sector should liaise with public bodies, informing them of what geospatial datasets they find valuable. The funding from private is crucial to the maintenance and upgrading of government held data.

Q12. Do you face challenges when working with geospatial data from across the public sector? If so, what are they and how could value be better released? Are there any technical remedies or standards that could be adopted to improve the interoperability of geospatial data? Please provide supporting evidence of what these remedies could help to accomplish.

-inaccuracy of coordinates. Specifically OS grid references being stored at 100m+ accuracy. Data points located at this level of accuracy are often useless to the end user (depending on use of course).

Q13. How can the Geospatial Commission act as a more effective customer for geospatial data on behalf of the public sector?

-by hosting a Government supported free-data repository. Utilising the reach and exposure of .gov.

Q14. Are there any additional geospatial datasets, from the other partner bodies or other sources, that the public sector would derive significant benefit from having access to, that might have novel and valuable use cases? What would that access look like?

Broadening upon the excellent work that the Environment Agency have done in opening their data, but they still hold more data of use. -

Q15: How can we best ensure effective local authority coordination and sharing of best practise, using location data to better deliver public services?

-allow public services access to a single, shared geospatial database and mapping platform. This would counter issues with overlapping data and missing information.

Q16: As a result of this analysis, we are prioritising the exploration of possible initiatives in the high-value categories identified:

- **property and land**
- **infrastructure and construction**
- **mobility**
- **natural resources**
- **sales and marketing**

What are the existing or potential geospatial applications which could be scaled-up or developed in order to capture economic value? (We would particularly welcome responses from industry and other bodies engaged in these sectors.)

Regarding 'property and land', I again refer to the release/commercialisation/ capture of historical OS mapping. The UK has an extensive mining history which is often hidden on modern maps and in our landscapes. Revealing the hidden hazards would be immensely beneficial for lenders and purchasers in the property transaction process.
An Historic Land Use Database, or at least unlimited access to historic maps would become a successful asset.

Additionally OS MasterMap topo (vectorised) should be released as an affordable product, potentially subsidised by government. The access to MasterMap topo would allow more productivity and efficiency in smaller businesses/start-ups. Knowing the exact extent of a site and being able to directly use land parcel polygons cuts out the need for manual digitisation of boundaries.

Q17: Are there any other areas that we should look at as a priority?

-Satellite imagery capture and distribution. Specifically imagery that can identify vegetation change coverage (important for predicting landslides).

-The state of the UK's current addressing/parcels datasets is unnecessarily complicated. Currently there are 3 datasets, each sold/licensed separately through OS, Royal Mail and Land Registry: MasterMap Topo, AddressBase and National Polygon Dataset (NPD). The Commission needs to focus on amalgamating these datasets into a single offering. We want small businesses like Terrafirma to be able to access land parcel polygons with LR title numbers, addresses and UPRNs all included within each individual polygon feature.

Needing to purchase each entity separately and spend many man-hours combining the data is incredibly expensive and frustratingly time consuming.

Q18: What are the main potential private and public sector innovations that will rely on the use of geospatial data to rollout, and are there corresponding regulatory challenges?

-

Q19: How best can we make the UK's presence in the international geospatial world more visible?

By showcasing free to use geospatial data on international data platforms such as ESRI's Living Atlas or similar.

Q20: Where should the UK be looking for points of comparison overseas? Who are the other international exemplars? What best practice is being modelled overseas that we can learn from?

-State run licensing rounds for oil and gas exploration often involve the release of declassified seismic imagery. ie. PEMEX in Mexico's first licensing round.

Thank you for your time in completing your response to our call for evidence.

Any questions, please get in touch with the Geospatial Commission via geospatialcommission@cabinetoffice.gov.uk

Geospatial Commission: Call For Evidence Response Questionnaire

Please submit your completed questionnaire to:

geospatialcommission@cabinetoffice.gov.uk.

Other - please state	X (Public Body)

Call for evidence - three key themes

We have identified three high-level themes that could help our approach to setting a strategy which are as follows:

1. **Supporting innovation in the geospatial sector**, exploring how to secure cutting edge skills, the right access to data, and opportunities from emerging technologies for the geospatial sector itself
2. **Enhancing the UK's geospatial assets,** looking at how best to align interests, avoid duplication, and instill best practice across the whole public sector
3. **Driving investment and productivity in geospatial applications**, asking in which wider sectors the most value lies from better exploitation and use of geospatial data, in the UK and internationally

Our questions

Q1. Is our view of the geospatial data types accurate? If not, what should be included or excluded from this?

We believe that the four types of geospatial data identified are accurate.

Q2. In addition to current government policy, what are the areas of geospatial skills where the commission could best focus, to help ensure the necessary capability within the UK for the future?

We believe that an understanding of, and ability to deploy geospatial skills, needs to become inherent in non-GI roles for the UK to achieve maximum impact and value. For example geospatial data will play a key role within the Data Science domain (that we foresee as being key to industry over the next decade) but this is not a traditional GI role.

In our opinion the Chartered status offered by the AGI can be enhanced and made more prominent and recognised.

Q3. What are the geospatial skills needs and gaps in your organisations, how can these be most effectively addressed, and how can careers in the sector be best promoted?

We have a strong 'traditional' GIS function and will soon seek to expand using this as a core of a new data analytics and business intelligence function. We foresee a challenge in recruitment as we believe that when we go to market we will find Data Scientist or GIS candidates but very few who can blend the skills of both.

Q4. Are there any publicly or privately-held geospatial datasets that are currently challenging to access or use or of insufficient quality, but which you or your organisation would find valuable if these issues could be resolved? Please explain why this would be of value, and how access/quality could be improved?

Improve access/availability of marine topographic datasets. Effectively provide marine base mapping as an equivalent to OS Basemapping on land. This would mean vector versions of the data held within UKHO admiralty charts, data which is currently only provided by commercial resale partners. OGA is already on a pathway to make this type of data in an oil & gas related context available. Making this data available would support a fuller and better understanding of the marine space, supporting smarter usage/conservation of the seabed by all parties. Also would help sharing of derived data between organisations.

Q5: Do you anticipate that any changes will be needed to the both address data and the wider address ecosystem, to support emerging technologies? Please provide evidence of value to support any proposed changes.

No comment at present

Q6: How should the commission be looking to develop the UK's capability in Earth observation data, both technologically and to support an effective market?

Readily accessible and pre-processed Earth Observation data, either live or semi-live (e.g. time delayed) could provide benefits for monitoring difficult to access terrain, for example foreshore, for multiple uses e.g. to support health and safety concerns submitted by the general public

Q7. Which new technologies should the commission focus on to provide new opportunities to process and exploit geospatial data for economic growth?

No comment

Q8. How can geospatial data and applications be used to support enhanced roll-out of future technologies?

No comment

Q9: What are the options for how public sector organisations could continue to invest in maintaining and enhancing our geospatial data assets?

We believe that a 'freemium' model could be adopted to strike a balance between universal barrierless access to fundamental datasets and the need to maintain and develop these through the licencing of advanced attributes or additional geospatial fields.

Q10: What areas of the underpinning geospatial infrastructure such as positioning technologies, including GPS and indoor positioning systems, and geodetic networks and frameworks to support them, should we be prioritising the development of, in order to support the emerging requirements for geospatial data?

No comment.

Q11: What role should the private sector have in both the development and maintenance of the underpinning infrastructure and enhancing the UK's geospatial data assets?

Where appropriate it should be mandated that data collected by industry should be stored in the national DAC's or systems equivalent to The Crown Estates Marine Data Exchange so that once this information is no longer commercially sensitive it can be freely accessed by all interested parties. This will reduce the need to resurvey.

Whilst not 'private sector' we believe that crowd-sourcing should not be underestimated.

Q12. Do you face challenges when working with geospatial data from across the public sector? If so, what are they and how could value be better released? Are there any technical remedies or standards that could be adopted to improve the interoperability of geospatial data? Please provide supporting evidence of what these remedies could help to accomplish.

No comment.

Q13. How can the Geospatial Commission act as a more effective customer for geospatial data on behalf of the public sector?

We believe that a single source of access for geospatial data would be beneficial, and the Geospatial Commission could facilitate this.

Q14. Are there any additional geospatial datasets, from the other partner bodies or other sources, that the public sector would derive significant benefit

from having access to, that might have novel and valuable use cases? What would that access look like?

We believe that the great benefit can be derived through the inclusion of OSNI data within the Geospatial Commissions remit.

Additionally, specifically in the marine space there is a lack of a publicly available dataset of submarine cables. The cables industry has been historically very reluctant to share the data which complicates offshore development. We believe the Geospatial Commission has a role to champion such datagaps within government and put in place plans to close these.

Q15: How can we best develop a single UK strategy, ensuring alignment between the individual strategies across the UK while still allowing for regional variations?

No comment.

Q16: How can we best ensure effective local authority coordination and sharing of best practise, using location data to better deliver public services?

No comment.

Q17: As a result of this analysis, we are prioritising the exploration of possible initiatives in the high-value categories identified:

- **property and land**
- **infrastructure and construction**
- **mobility**
- **natural resources**

- **sales and marketing**

What are the existing or potential geospatial applications which could be scaled-up or developed in order to capture economic value? (We would particularly welcome responses from industry and other bodies engaged in these sectors.)

Commenting specifically on the Property category, Internal Navigation, BIM and Building Management Systems hold great potential as they are either inherently geospatial, or can be enhanced by geospatial. All are emerging technologies/fields.

Q18: Are there any other areas that we should look at as a priority?

No comment.

Q19: What are the main potential private and public sector innovations that will rely on the use of geospatial data to rollout, and are there corresponding regulatory challenges?

No comment.

Q20: How best can we make the UK's presence in the international geospatial world more visible?

Development of global leading projects and standards and seek to capitalise these by converting them into a marketable commodity that can be exported.

Q21: Where should the UK be looking for points of comparison overseas? Who are the other international exemplars? What best practice is being modelled overseas that we can learn from?

No comment.

Thank you for your time in completing your response to our call for evidence.

Call for evidence - three key themes

We have identified three high-level themes that could help our approach to setting a strategy which are as follows:

1. **Supporting innovation in the geospatial sector**, exploring how to secure cutting edge skills, the right access to data, and opportunities from emerging technologies for the geospatial sector itself
2. **Enhancing the UK's geospatial assets,** looking at how best to align interests, avoid duplication, and instill best practice across the whole public sector
3. **Driving investment and productivity in geospatial applications**, asking in which wider sectors the most value lies from better exploitation and use of geospatial data, in the UK and internationally

Our questions

Q1. Is our view of the geospatial data types accurate? If not, what should be included or excluded from this?

I think it is accurate but needs to be expanded to cover funding. Without adequate funding in place, a lot of ideas or best practices just won't happen. Councils need to balance their books.

Innovation needs to include both private and public sector organisations and companies.

Q2. In addition to current government policy, what are the areas of geospatial skills where the commission could best focus, to help ensure the necessary capability within the UK for the future?

It would be useful to have some focus on cartographic principles. This is useful when need to produce maps or display data online or on printed maps.

Database and programming knowledge is also extremely useful.

I think the British Cartographic Society should be included when it comes to cartographic side of it.

On the job training could be useful for some people.

My work involves dealing with mapping and addressing. This covers Local Land and Property Gazetteer; Local Street Gazetteer; Street Naming and Numbering and GIS. I also deal with spatial data exports and loads and run spatial queries.

There is no national course for Street Naming and Numbering, yet that discipline, determined an address of a new property. There are courses for LSG and LLPG, run by GeoPlace.

Q3. What are the geospatial skills needs and gaps in your organisations, how can these be most effectively addressed, and how can careers in the sector be best promoted?

My work involves dealing with mapping and addressing. This covers Local Land and Property Gazetteer; Local Street Gazetteer; Street Naming and Numbering and GIS. I also deal with spatial data exports and loads and run spatial queries.

I am in a Data Management Team which is tasked with the above, as part of a Shared IT and Digital Service for Kingston and Sutton.

However although we deal with the above, Sutton didn't want to remove the GIS responsibilities from their performance and insight team. The people in that team who remain, since one left to take a job with us, are not as experienced. We are currently providing one member of staff to help.

So there is a skills shortage in some parts of councils but in each council it will be different.

Kingston Council also has a Data and insights team, who have recently been rebranded. They deal with demographics. This is useful but the person who really understood GIS there left and hasn't been replaced. Newham Council recently showcased what they were doing through data mining to work out when and where to best target resources. I doubt people in the Data and Insights Team would have the skills to do that.

The skills may exist elsewhere in the council but it's matching the people up for the work required. It also needs to target management and make them understand why such potential change would be useful.

Highways is a shared service across Kingston and Sutton and they have a skills shortage when it comes to the data side of Highways. If you ask them if a road is adopted, they may not easily be able to find out. They should maintain a Highways register of officially named streets but we know this to be out of data.

When we have asked them to update the operational districts file, this has not always been done as they don't know how to do this. Similar for special events that need to be recorded in the LSG.

Then there is the special engineering difficulty. However if you ask them about road defects or Street name plates they could help.

Strategic planning had a GIS person but they were not replaced when they joined our team.

There was a heritage conservation office but their job wasn't renewed. Whilst it's not directly related to GeoSpatial data, it is useful when it comes to listed buildings and queries with them.

Q4. Are there any publicly or privately-held geospatial datasets that are currently challenging to access or use or of insufficient quality, but which you or your organisation would find valuable if these issues could be resolved? Please explain why this would be of value, and how access/quality could be improved?

Trying to get hold of National Grid gas data is impossible. I did bump into someone, by chance, at a training course who might have been able to help but I never heard back from my email. I was too busy to chase them.

Whenever I contact the customer services I am directed to their high level electricity data set, even when I explain that isn't what I'm looking for.

Data on the location of broadband and telephone cables would be useful would be useful.

It would be useful if we could use the Green Openspaces for London dataset more widely, along with some of the information displayed in their Web mapping, which isn't available for download. However license restrictions apply. Also it was deemed not to have been used enough and the £2,000 better spent elsewhere so removed.

Access to the Postal Address File would be useful.

Historic Ordnance Survey maps, scanned by Landmark and sold under a license are only in black and white and are missing the marginalia. So one can't see

when the map was surveyed. It would be useful if more Higher resolution monochrome versions were available. The library of Scotland has done some work to make historical mapping available.

I am not certain if they charge for use but if that was widely available if could be useful.

It would be useful if there was a central repository for data or contacts for people who own data. For example if one wishes to get hold of Network Rail dsts in their railway lines, who does one contact?

Land Registry data is not easy to come by. They charge for tile. Some information is available under INSPIRE but it's from 2014 and doing a brief search on data.gov.uk, I couldn't find their data for Kingston.

Q5: Do you anticipate that any changes will be needed to the both address data and the wider address ecosystem, to support emerging technologies? Please provide evidence of value to support any proposed changes.

Cleansing of address and street gazetteers will be important. Some of the issues encounter may require historical research as you can't go amending addresses without good reason.

Without access to good quality address data that wider ecosystem won't function as well.

Street data that is accurate and detailed will be increasing useful but it needs people with the right skills and mindset to update it and keep it updated.

Managers and senior staff need to understand the benefit or posts will be deleted or held open when people leave.

ooped examples and ideas of how one can use data to make improvements and efficiency savings.

When I left I felt I wasn't in a position to use any of it at work as we are still supporting legacy systems. Whilst these are being decommissioned, in their place is partly other systems that are from the dark ages.

The problem faced is that some companies come in during procurement exercises and charge so little for their product that they win on price alone. Then when you get them in you find the software isn't great and if you need to do certain things, they charge you a lot of money to do it for you.

You may say but you never told us we couldn't do this ourselves. They then respond but you never asked.

A nice more honest and modern company then doesn't get a look in because they were coming out at a higher cost. Of course with their software these things the other company charged for, can be done by yourself.

We need GeoSpatial staff in place to support the future. They need access to modern tools.

Back in about 2001, a then ground breaking system, Intergrated Spatial Information System [ISIS] was designed and released. In time however it stopped being ground breaking. Then it out lived its welcome.

However the users who used it for planning and Building Control, amongst others, liked it. So trying to convince others in other departments for the need too change is not easy.

One needs to get buy in from senior management.

Q6: How should the commission be looking to develop the UK's capability in Earth observation data, both technologically and to support an effective market?

If we could be involved in Galileo but as we are leaving the EU it may not be possible.

Do we need to build and launch our own satellite?

Aerial photography data was made avilable to LGAs. However this data for Kingston the data is from 2013 and 2015, as well as possibly other years. So when a planning enforcement colleague had a query, the aerial photography couldn't be relied upon.

Q7. Which new technologies should the commission focus on to provide new opportunities to process and exploit geospatial data for economic growth?

Drones and the data they could provide would be useful.

I can see the benefit but at work I'm tied up doing with supporting ISIS and I don't know if the people who might look at technology, would understand how this might be useful solution. Similar applies to data skills and how working with big data could bring about change but people with the right skills might not exist in an organisation or they exist but are not involved.

Q8. How can geospatial data and applications be used to support enhanced roll-out of future technologies?

GeoSpatial data can be used to roll out high speed broadband. It could also be used to locate mobile blackspots. Currently there are areas where mobile companies claim their to be a good coverage outside but actually there is not. This is evident in Surbiton when connecting to O2 mobile phone data.

The other week I attended a Data4good conference in London. Lots of hooped examples and ideas of how one can use data to make improvements and efficiency savings.

When I left I felt I wasn't in a position to use any of it at work as we are still supporting legacy systems. Whilst these are being decommissioned, in their place is partly other systems that are from the dark ages.

The problem faced is that some companies come in during procurement exercises and charge so little for their product that they win on price alone. Then when you get them in you find the software isn't great and if you need to do certain things, they charge you a lot of money to do it for you.

You may say but you never told us we couldn't do this ourselves. They then respond but you never asked.

A nice more honest and modern company then doesn't get a look in because they were coming out at a higher cost. Of course with their software these things the other company charged for, can be done by yourself.

We need GeoSpatial staff in place to support the future. They need access to modern tools.

Back in about 2001, a then ground breaking system, Integrated Spatial Information System [ISIS] was designed and released. In time however it stopped being ground breaking. Then it outlived its welcome.

However the users who used it for planning and Building Control, amongst others, liked it. So trying to convince others in other departments for the need to change is not easy.

One needs to get buy in from senior management

Q9: What are the options for how public sector organisations could continue to invest in maintaining and enhancing our geospatial data assets?

The use of drones and data mining could help public sector organisation's modernise what they do. However this requires modern software and skills.

Currently some councils are supporting legacy systems or getting in computer systems built in the dark ages. These may not be good but they are cheap.

This hinders innovation and isn't the best use of funds. However because they are cheap councils feel they have no choice but to award them as the contact. Sometimes exemption reports can then be written but this is only after months of issues.

We are currently undertaking address matching with the council Revenues and Benefits system and Electoral Register.

If we find properties in the Revenues and Benefits system that are on the wrong street, they have to amnauuky move across each case. This is time consuming and could lead to errors.

They recently looked into procuring a new system. However it was deemed the competition wasn't much better so they rewarded the contact to the same company.

So if something could be done to widen the private sector companies building software for the public sector, this will free up Officer time to do so much else.

To continue to enhance the Geospatial datasets we need people who understand their value and what can be done with them. We need to invest in staff who can then invest in the data if you don't invest in staff they will go to the private sector.

Q10: What areas of the underpinning geospatial infrastructure such as positioning technologies, including GPS and indoor positioning systems, and geodetic networks and frameworks to support them, should we be prioritising the development of, in order to support the emerging requirements for geospatial data?

We need to improve the mobile data connectivity. O2 for example claim good coverage outdoors on O2, yet in parts of the town it's non existent despite claims it is good.

So their needs to be more data monitoring of the data provided by large organisations about themselves and their service.

We need 5G to come on stream. Galileo satellite would be useful but the EU may prefer us to not be involved as we are leaving the EU. How much would it cost to

build our own?

Q11: What role should the private sector have in both the development and maintenance of the underpinning infrastructure and enhancing the UK's geospatial data assets?

The private sector could help fund innovation, for example through software innovation, if done fairly. However, having companies like iDox, who use very old system architectures and charge little for the product, don't help as they keep winning work, despite the software not being modern or as good as some rivals.

Q12. Do you face challenges when working with geospatial data from across the public sector? If so, what are they and how could value be better released? Are there any technical remedies or standards that could be adopted to improve the interoperability of geospatial data? Please provide supporting evidence of what these remedies could help to accomplish.

The challenges faced relate to organisational structures and remits. Better value could be released if we could work with the best outcomes.

For example SOCTIM provided funding for digital work via a private company. As a result work was found for them to do, to justify the money being given. However the company wasn't an expert in the area being worked upon. A better solution existed which may even have been cheaper but because this funding needed to be used for something it was kind of shoehorned in.

GeoSpatial data needs to be accessible across multiple systems. This isn't always possible. For example an ArcGIS platform can't read MapInfo TAB files. There are software packages that will do the translations but those cost.

Politics also plays a part. So someone may want to do something their way because it gives other people something to do. So they reinvent the wheel when it is not needed.

Q13. How can the Geospatial Commission act as a more effective customer for geospatial data on behalf of the public sector?

It needs to promote what the public sector can offer.

Could the public sector make money by offering their services to the private sector? Thinking commercially would be a different mind set.

It needs to promote the kind of jobs that the public sector could offer. This would be to applicants and senior council staff.

Q14. Are there any additional geospatial datasets, from the other partner bodies or other sources, that the public sector would derive significant benefit from having access to, that might have novel and valuable use cases? What would that access look like?

Royal Mail Postal Address File including Multiple Occupancy File and Not Yet Built File.

Please also see answer to question 4, as it is relevant here.

Q15: How can we best develop a single UK strategy, ensuring alignment between the individual strategies across the UK while still allwoing for regional variations?

We need a direction of travel plan setting out how we want the future to be. From this different industry bodies might be able to take strands and further develop those.

There would need to be oversight of this to ensure the standard was high and consistent.

I like the INSPIRE directive, it needs to be something understandable.

At work we now talk about plans of action rather than strategy. Could there be plans of action from the Geospatial Commission.

Could more agile methods of working be allowed to spatial data work.

Q16: How can we best ensure effective local authority coordination and sharing of best practise, using location data to better deliver public services?

We need a local government body tasked with ensuring effective of geospatial data. This however needs to encompass not just technical people but also a managers and directors, as well as councilors so that local buy in to this can be seen.

I have been to conferences, such as Data4good and can see uses for what was being showcased and discussed. However I don't have the time and nor am I in a position to make use of any of it. Technically it was a waste of time me going for work, although on a personal interest level it was good. There are other people for whom it might have been useful to attend and in future I shall encourage it.

We also need to find a way of stopping companies bidding cheap to win work when their systems are poorly designed or they charge of extras you need but aren't aware of. This doesn't help people make best use of location data.

It's not fair on those modernising and being honest in their bidding process tenor.

Q17: As a result of this analysis, we are prioritising the exploration of possible initiatives in the high-value categories identified:

- **property and land**
- **infrastructure and construction**
- **mobility**
- **natural resources**
- **sales and marketing**

What are the existing or potential geospatial applications which could be scaled-up or developed in order to capture economic value? (We would particularly welcome responses from industry and other bodies engaged in these sectors.)

Not certain.

Q18: Are there any other areas that we should look at as a priority?

The funding of all of this needs to be looked at. If it's not funded properly and more data is made available for free, the quality will drop.

Where I work they are funding two additional posts but these are only for 18 months. We may struggle to get people in as who wants an 18 month post when it isn't a contract but a permanent member of staff. I thought about applying for a senior role but the chances of being seconded are allowed as I have knowledge of obsolete systems we wish to try and get rid of but until they go need to be supported.

It needs to look at whether broadband and phone services should be considered essential infrastructure that can offer utility companies the ability to dig up roads under emergency powers.

Q19: What are the main potential private and public sector innovations that will rely on the use of geospatial data to rollout, and are there corresponding regulatory challenges?

High speed broadband; location of Internet connected street furniture; property; land and street data. The challenges in this are if the Data existing is of poor quality or simply of mix quality.

Until it is cleansed one may not have the correct answer.

In the past some Street Naming and Numbering hasn't always been up to the same guidelines we use now. In some cases there is a need to investigate whst was done in the past as the naming and numbering of properties and streets is a legal process. Doing research on this can be slow and time consuming. However if we want modern reliable address data, it needs to be completed.

Other challenges might be political. So someone might want to do something one way because that is what they know and have skills in. If they could be reskilled to where it's needed it may help. However it costs.

Q20: How best can we make the UK’s presence in the international geospatial world more visible?

We need to make the data available of internally recognisable platforms. We need to attend conferences and markets aimed at GeoSpatial Data.

We need to sell our skills. The Ordnance Survey provide consultation support to other countries and have in the past even mapped some of these countries. We need to build upon this without organisations.

Q21: Where should the UK be looking for points of comparison overseas? Who are the other international exemplars? What best practice is being modelled overseas that we can learn from?

I don't know much about the foreign market but it might be interesting to see what the French and Swizz are doing as certainly they do produce good national series of maps

Thank you for your time in completing your response to our call for evidence.

Any questions, please get in touch with the Geospatial Commission via geospatialcommission@cabinetoffice.gov.uk

Geospatial Commission: Call For Evidence Response Questionnaire

Please submit your completed questionnaire to:

geospatialcommission@cabinetoffice.gov.uk.

Clearly title your email *'Call for evidence response'*.

About you and your organisation

Micro business (up to 9)	

Other - please state	

Call for evidence - three key themes

We have identified three high-level themes that could help our approach to setting a strategy which are as follows:

1. **Supporting innovation in the geospatial sector**, exploring how to secure cutting edge skills, the right access to data, and opportunities from emerging technologies for the geospatial sector itself
2. **Enhancing the UK's geospatial assets,** looking at how best to align interests, avoid duplication, and instill best practice across the whole public sector
3. **Driving investment and productivity in geospatial applications**, asking in which wider sectors the most value lies from better exploitation and use of geospatial data, in the UK and internationally

Our questions

Q1. Is our view of the geospatial data types accurate? If not, what should be included or excluded from this?

The Geospatial data types listed cover a broad spectrum, but the descriptions are very weighted towards traditional GIS and don't cover, by that definition, the type of large scale, detailed surveying (Land, Utility and Hydrographic data capture) that form the corner stones and foundations of any quality data set. Use of the word 'place' instead of 'position' reinforces this GIS language.

Q2. In addition to current government policy, what are the areas of geospatial skills where the commission could best focus, to help ensure the necessary capability within the UK for the future?

Focus has been shifted away from traditional land surveying techniques to data capture utilising black box technology. As this technology further develops, surveyors of the future will be data managers but with little in the way of theoretical knowledge to quality assure the valuable data collected. The commission should ensure land and hydrographic surveying is supported and promoted as a professional service offering and it is critical that government agencies interface with SMEs, many of whom are represented by TSA, to develop mutual understanding and support and to recognise and trust the quality of SME data collection and presentation.

Q3. What are the geospatial skills needs and gaps in your organisations, how can these be most effectively addressed, and how can careers in the sector be best promoted?

There is a significant skills shortage at Geospatial sciences grass roots level and whilst the recently approved Geospatial Sciences and Mapping Apprenticeship will go some way to plugging the gap, it needs considerable focus from the commission to support this and promote at secondary school level land/utility/hydrographic surveying as a career choice. This should be through incorporating the work of a 'Class of Your Own' and their Design Engineer Construct curriculum into schools creating the link to those teaching the level 3/6 apprenticeships and higher education. The course currently run at TSA's Survey School provides an opportunity for formal training and qualifications in land survey where experienced technical surveyors can enhance their theoretical and practical knowledge. This is a skills gap often overlooked and one that greatly enhances the quality of data capture and delivery across a wide range of industry sectors.

Q4. Are there any publicly or privately-held geospatial datasets that are currently challenging to access or use or of insufficient quality, but which you or your organisation would find valuable if these issues could be resolved? Please explain why this would be of value, and how access/quality could be improved?

Data collected, licensed by TSA members, is of a significant value and TSA would welcome further discussion with the Geospatial Commission on how we can work in partnership to unlock the potential of these datasets for the benefit of all. This has particular merit in the utility mapping sector, where utility providers' geospatial datasets are often historic and originate from sources of varying quality. Access to foundation datasets, such as LiDAR, DEM and aerial photography, is still constrained.

Q5: Do you anticipate that any changes will be needed to the both address data and the wider address ecosystem, to support emerging technologies? Please provide evidence of value to support any proposed changes.

NA

Q6: How should the commission be looking to develop the UK's capability in Earth observation data, both technologically and to support an effective market?

The commission should look to work with TSA and in discussion with their membership to ensure developments in this area benefit both public and private sectors. By harvesting the combined knowledge of TSA membership, the impact of these developing and emerging technologies to market can be optimised.

Q7. Which new technologies should the commission focus on to provide new opportunities to process and exploit geospatial data for economic growth?

The land, utility and hydrographic survey industries rely on evolving and new technologies to stay at the forefront of efficient data collection and processing, ultimately adding value to stakeholders and clients. What the commission does need to look at is how these new technologies are regulated within industry, managed and operated by suitably qualified professionals. Currently there are too many early adopter 'hobbyists' who have little or no geospatial sciences qualifications utilising these new technologies (such as drones) to compete against reputable survey companies.

One key bottleneck is the telecoms / internet data transfer speed available for users transmitting increasingly large geospatial datasets.

Q8. How can geospatial data and applications be used to support enhanced roll-out of future technologies?

The commission should look to work with TSA and, in discussion with their membership, to ensure the vast experience the membership can bring in this area will benefit both public and private sectors. Land, Utility and Hydrographic professionals are early adopters of technology and develop workflows at the front end of the technology lifecycle to ensure efficiencies are captured through developing 'lean' geospatial data capture and processing applications.

Q9: What are the options for how public sector organisations could continue to invest in maintaining and enhancing our geospatial data assets?

Public Sector organisations should look to work with professional Land, Utility and Hydrographic Survey companies to ensure the quality and integrity of their geospatial datasets are maintained. Often public-sector organisations procure survey data as a commodity service rather than a professional one, using the 'cheap is best' mantra. Many of these organisations do not have embedded survey professionals on the procurement team so tenders are evaluated based on minimal technical input. Or they are evaluated using standard procurement matrices which value cost over technical compliance. This puts the integrity of the commissioned datasets at risk.

Q10: What areas of the underpinning geospatial infrastructure such as positioning technologies, including GPS and indoor positioning systems, and geodetic networks and frameworks to support them, should we be prioritising the development of, in order to support the emerging requirements for geospatial data?

The importance of OSNet is now critical to most geospatial data collection, and devices that provide OSTN15 / OSGM15 coordinates are in universal use in the professional surveying and construction environment. Maintenance and enhancement of this network, with support for partner network correction service providers, is essential for the future. The use of this universally accessible coordinate system is vital to BIM applications on many construction projects.

See also answer to question 8.

Q11: What role should the private sector have in both the development and maintenance of the underpinning infrastructure and enhancing the UK's geospatial data assets?

This is an extension to the answer given in question 9. The commission should look to collaborate with TSA and in discussion with their membership to ensure development and maintenance in this area benefits both public and private sectors. By harvesting the combined knowledge of TSA membership, the vast collective experience in this area can be exploited. The private sector has a uniquely varied experience of geospatial data collection and this experience is an underused resource at high level in the Public sector.

Q12. Do you face challenges when working with geospatial data from across the public sector? If so, what are they and how could value be better released? Are there any technical remedies or standards that could be adopted to improve the interoperability of geospatial data? Please provide supporting evidence of what these remedies could help to accomplish.

Again, this is an extension to question 9 and the commission should work with TSA to look at how procurement of geospatial data can be managed to add real value to the public sector. The mantra of 'survey once; use many times' is often quoted but seldom adopted in the public sector, costing tax payer's money and is unregulated. TSA are constantly looking to drive up standards and the Geospatial commission can support by looking at how the public sector procures geospatial data and the selection criteria used for evaluating tenders.

An example of this is the support (both commercial and technical) to the development of PAS128 Specification for underground utility detection, verification and location. Currently TSA are working on a pilot with Lloyds Register to create an accreditation to PAS128, which survey companies can use as evidence of competency in this area of Geospatial data capture, processing and management. Without support of both public and private sector clients to recognise this as a standard of competence in this area, this becomes just another badge and companies will 'buy cheap', undermining what PAS128 as a British Standard was developed for**.**

Q13. How can the Geospatial Commission act as a more effective customer for geospatial data on behalf of the public sector?

Previous answers in Questions 9-12 cover this.

Q14. Are there any additional geospatial datasets, from the other partner bodies or other sources, that the public sector would derive significant benefit from having access to, that might have novel and valuable use cases? What would that access look like?

TSA membership work for many public-sector clients and the commission should look to work with TSA and in discussion with their membership to ensure the vast experience the membership can bring in this area will benefit the public sector. TSA look to ensure the geospatial datasets captured for public sector clients adopt the mantra of 'survey once; use many times', but at a local level, surveys are commissioned of the same geographical area, often to similar specifications by different departments within the same public-sector organisation. This not only costs the tax payer money but creates quality conflict through uneducated specification commission and devalues the dataset for future use. We believe that this collaboration would have value in regard to utility mapping data, where our data can have a significant positive impact on health and safety during excavation.

Q15: How can we best ensure effective local authority coordination and sharing of best practise, using location data to better deliver public services?

Treat procurement of geospatial datasets as a professional service offering and not a commodity service, where qualified professional surveyors manage the procurement process and sit on tender evaluation teams. Build a cross local authority Geospatial Management team of these individuals to share through a community of practice, lessons learned, and this will enhance the quality of future datasets for a variety of uses to improve public sector services. Local authority funding and budgets need to allow data sharing. Their hands are often tied as money is awarded for a specific project which delivers to a bespoke in-house system. A more generic/releasable dataset is usually more expensive as, for example, it requires effort to determine IPR release or more resource to deliver data in a format that suits both the LA's dataset and more open source ones. This is then outside of the funding remit so not undertaken.

Q16: As a result of this analysis, we are prioritising the exploration of possible initiatives in the high-value categories identified:

- **property and land**
- **infrastructure and construction**
- **mobility**
- **natural resources**
- **sales and marketing**

What are the existing or potential geospatial applications which could be scaled-up or developed in order to capture economic value? (We would particularly welcome responses from industry and other bodies engaged in these sectors.)

Applications that offer considerable value but are often not linked to long term economic value include flood mapping for hydraulic modelling, Utilities Survey to PAS128, Survey4BIM, terrestrial laser scanning and mobile mapping, deformation monitoring, measured building surveys, high precision GNSS control, topographical mapping and implementation of Virtual Reality and Augmented Reality.

Q17: Are there any other areas that we should look at as a priority?

- Delivery of PAS128 surveys by accredited organisations/companies
- Support Survey4BIM's BIG5 Geospatial Challenges
- UK Cadastral System

Q18: What are the main potential private and public sector innovations that will rely on the use of geospatial data to rollout, and are there corresponding regulatory challenges?

N/A

Q19: How best can we make the UK's presence in the international geospatial world more visible?

Promotion and support by the Geospatial Commission at industry conferences such as the annual GeoBusiness conference and TSA conferences, will raise the profile of the private sector survey profession and therefore offer a networking gateway to the global reach of the companies that operate within it.

Work with Industry bodies who already have these relations to offer support and utilise relevant adjacencies to build on existing relationships. For example, TSA recently hosted a Chinese delegation (lead by He'nan Administration of surveying.mapping and Geo-information) at the HQ of the RICS.

Q20: Where should the UK be looking for points of comparison overseas? Who are the other international exemplars? What best practice is being modelled overseas that we can learn from?

The approach to geospatial procurement and management of valuable datasets by the He'nan Administration of surveying.mapping and Geo-information should be explored further.

The commission should look to work with TSA and in discussion with their membership to ensure the vast experience in international expertise the membership can bring in this area is captured.

Thank you for your time in completing your response to our call for evidence.

Call for evidence - three key themes

We have identified three high-level themes that could help our approach to setting a strategy which are as follows:

1. **Supporting innovation in the geospatial sector**, exploring how to secure cutting edge skills, the right access to data, and opportunities from emerging technologies for the geospatial sector itself
2. **Enhancing the UK's geospatial assets,** looking at how best to align interests, avoid duplication, and instill best practice across the whole public sector
3. **Driving investment and productivity in geospatial applications**, asking in which wider sectors the most value lies from better exploitation and use of geospatial data, in the UK and internationally

Our questions

Q1. Is our view of the geospatial data types accurate? If not, what should be included or excluded from this?

The Wildlife Trusts welcome the opportunity to comment on the Geospatial Commission's Call for Evidence. The Wildlife Trusts are considerable collators, holders and uses of geospatial data. Much of our work is driven by a spatial understanding of the natural environment.

There is a Wildlife Trust caring for wildlife and wild places near you. We have a shared mission to create an environment rich in wildlife for everyone. We know that a healthy natural environment is the source of our prosperity and our wellbeing. We want to inspire people about the natural world so that they value it, understand their relationship with it and take action to protect and restore it. We are actively engaged in the planning system, promoting opportunities to improve the natural environment and reviewing more than 60,000 planning applications a year. We have more than 800,000 members including 150,000 members of our junior branch Wildlife Watch. Every year we work with thousands of schools and our nature reserves and visitor centres receive millions of visitors. Each Wildlife Trust is working within its local communities to inspire people about the future of their area: their own Living Landscapes and Living Seas.

The Call for Evidence consultation document states that *"The overarching objectives of the Commission are to increase economic growth and improve social and environmental outcomes"*. However, the document fails to recognise the importance of environmental spatial data to business and to the public sector, and ultimately, the economy. **The Wildlife Trusts believe that greater emphasis should be given to the importance of geospatial data for the environment**, not just for environmental decision making but for the sustainable development, economic and social benefits from having good geospatial data on the environment.

Nature Recovery Network
In the Government's 25 Year Environment Plan[1], they committed to "develop a **Nature Recovery Network** providing 500,000 hectares of additional wildlife habitat, more effectively linking existed protected sites and landscapes, as well as urban green and blue infrastructure" and that "we will develop maps and advice to show where actions to improve and restore habitats would be most effective".

A Nature Recovery Network is a **joined-up natural system of places important for wild plants and animals, on land and at sea**. This network of interconnected wildlife-rich places allows ecological processes to function. It includes all the places where these processes contribute to flood-risk management, carbon storage, improved air quality, water purification, outdoor recreation, community cohesion, cultural inspiration, education, health and wellbeing. It brings value to people.

This **spatial plan for the environment** would ensure public spending and investments result in well informed decision making that is better targeted, more effective and delivers multiple benefits. It would also enable better and faster decision making on housing and commercial development and infrastructure, by providing robust and easily available information on risks, opportunities and synergies to help plan land use and allocate development sites. It would **enable more efficient targeting of public, private and charitable funding in the urban and rural environment to contribute to nature's recovery**. The existence of such maps would bring benefits in the improved targeting of advice and other effort related to a number of central government strategies (such as the National Pollinator Strategy). It could contribute to cost reduction in various public-sector areas, for example by aligning green infrastructure provision with those areas suffering from health inequalities, and by informing rural and farming subsidies to secure the most effective delivery of public goods. By combining environmental and social data this mapping will benefit businesses, the public sector and the environment sector, helping to plan and locate activities and projects in a way that will deliver better outcomes and give the highest return on investment, whilst having a net positive impact on the environment.

The process of **targeting and distributing agricultural payments** to generate publicly beneficial environmental goods and services would be enhanced considerably if it was contributing to a coherent spatial plan for nature's recovery.

The role of Nature Recovery Maps in providing specific spatial focus would enable more **effective and efficient investment of "environmental net gain" funding from developers**. In addition, the National Infrastructure Commission is tasked with identifying strategic infrastructure needs that would enable significant opportunities for economic development. As illustrated by the current proposals for the Oxford to Cambridge Expressway and associated development, their work does not include a strategic consideration of the environment, so it inevitably prioritises hard infrastructure and other built development over protection of the natural environment at an early stage in the process, and overlooks opportunities for strategic development planning to contribute actively to nature's recovery (when this would bring significant social and economic benefits).

[1] HM Government (2018) *A Green Future: our 25 Year Plan to Improve the Environment*.

It would also **enable investment into natural capital** intended to enhance the provision of ecosystem services to generate cost savings, commercial income and/or investment returns. The Natural Capital Committee has demonstrated that the social and economic value of a healthy, ecologically functioning network or places that are rich in wildlife would be extremely high. Many businesses rely on natural capital and, despite the emergence of natural capital accounting, the value of these resources to a business are not currently truly recognised or appreciated. For example, the manufacturing and food sectors rely on having a regular and plentiful supply of clean water (e.g. breweries, car manufacturers). In March 2018, both Jaguar Land Rover in Solihull and the Cadbury's Factory at Bourneville had to cease production when their water supply was interrupted (due to burst water mains following the cold weather).

Developing Nature Recovery Maps is key to supporting both the recovery of wildlife and the **improvement of public health**, by increasing regular access to nature for all. Currently, those living in the most deprived areas are ten times less likely to live in the greenest areas. Lack of access to nature is a significant factor in health inequality, leading to increased mental and physical health risks. Natural England has estimated that if every household in England were provided with good access to quality green space (enabled in future by creation of a Nature Recovery Network), it could save an estimated £2.1 billion in healthcare costs[2].

The Wildlife Trusts believe that local authorities should be required, with full support and funding from central government, to develop **Local Nature Recovery Maps** to achieve these objectives, and to embed them in local plans. These maps and plans would then guide decisions on housing and development to ensure they make a positive contribution to nature's recovery. They would also inform strategic decisions on the targeting of public funding for farming and land management, to maximise the positive impact on wildlife. And they would guide other forms of regulation and investment to maximise their effective contribution to nature's recovery.

The Conservative Party Manifesto 2017 committed to creating a geospatial data body within government but it also committed to ensure this new body "set the standards to digitise the planning process and help create the most comprehensive digital map of Britain to date"[3]. Any national map **must** include environmental geospatial data.

Environment Bill

The Wildlife Trusts are also part of the Greener UK Coalition. We are calling for an ambitious Environment Bill intended to ensure the recovery of nature for the benefit of wildlife and our own health, wellbeing and prosperity. We believe a Westminster Environment Bill must:

1. Set ambitious and measurable goals for nature's recovery and a healthy environment including new legally binding targets
2. Deliver improved access to nature and map a network that makes space for wildlife

[2] Natural England (2009). Technical Information Note 055 – 'An estimate of the economic and health value and cost effectiveness of the expanded WHI scheme 2009'

[3] The Conservative and Unionist Party Manifesto (2017) *Forward, Together. Our plan for a Stronger Britain and Prosperous Future.*

3. Enshrine strong environmental principles and create an effective independent watchdog.

Having access to up-to-date, comprehensive geospatial data is **essential** for all three of those components.

Greener UK has also identified a set of thematic and time-bound objectives that should address at least the following:

- **A healthy environment**
  - *a. Air quality is safe for human health and the environment;*
  - *b. Our freshwaters and seas achieve good ecological status and good environmental status respectively, able to support a wide diversity of wildlife;*
  - *c. Soils have been returned to a healthy status and any uses are sustainable;*
  - *d. The extent, quality and connectivity of habitats is increased and natural processes restored, so that ecosystems on land and at sea are resilient; and natural beauty and heritage enhanced in our landscapes;*
  - *e. The richness of species is maintained and their abundance maintained at, or restored to, at least favourable conservation status on land, in freshwater and at sea, with human-caused extinctions prevented;*

- **People engaged and empowered**
  - *f. Everyone has access to high quality natural greenspace where they live, to contribute to their wellbeing, mental and physical health;*
  - *g. Environmental justice is delivered for all, including the poorest in society and future generations;*
  - h. *Everyone receives an inspiring environmental education and environmental matters are properly communicated to and understood by the public;*

- **Our impacts managed**
  - *i. Climate change drivers are addressed and the environment is managed to deliver our long-term climate change adaptation and mitigation goals, for example habitat connectivity and carbon storage in soils, deep peat and forests;*
  - *j. New invasive species, pests and diseases are not being introduced to or becoming established in the UK, and those already here are at least under effective control with their harmful impacts addressed;*
  - *k. Where natural or manufactured resources are used, this is done sustainably and equitably, and our waste has no negative impact on the environment;*
  - *l. The UK economy is operating within its fair share of global environmental limits, with the UK's overall impact on the global environment being net positive; and*
  - *m. Chemicals are manufactured, transported, stored, used and disposed of safely to protect people's health and the environment.*

Again, measuring progress towards these objectives will all require geospatial datasets some of which may currently exist but others may need to be developed.

Q3. What are the geospatial skills needs and gaps in your organisations, how can these be most effectively addressed, and how can careers in the sector be best promoted?

In recent years, the use of GIS has become integral to the ability of many Wildlife Trusts to deliver a wide range of core work. It is a powerful mapping tool but also a way to analyse complex data to aid planning, analysis, reporting and inform decision-making. As a result, there is a need for everyone to have a basic understanding of what GIS can do and how to interrogate the information. We believe that understanding spatial information should be a basic skill available to everyone in ecology and environmental activities, just as using word processing or spreadsheets.

There is also a need for more proficient GIS users and at least one highly proficient user in each Wildlife Trust. However, based on TWT experience, we are likely to benefit more from ecologists with GIS skills rather than GIS graduates with no ecological knowledge.

Many Wildlife Trusts are in the fortunate position to have an individual member(s) of staff responsible for GIS across, and therefore have internal support. Generally, The Wildlife Trusts find that often new graduates have GIS skills but it is staff members and decision-makers over the age of 35 that have had limited exposure to GIS – either training or in practice. The work of the Geospatial Commission could play a positive role in ensuing a culture change around the use of geospatial data in decision making.

The cost of software can actually be the barrier to individual Wildlife Trusts. The GIS software used by the various Wildlife Trusts differs across the country. Some have chosen to invest considerable resources into licenses for ArcView software. They have chosen ArcView over free GIS software (such as QGIS) or cheaper programmes (such as MapInfo) because of the increased functionality it provides in terms of being able to run GIS queries. ESRI still offers value for money but only for a limited number of users because of licensing costs and the expertise required.

Q4. Are there any publicly or privately-held geospatial datasets that are currently challenging to access or use or of insufficient quality, but which you or your organisation would find valuable if these issues could be resolved? Please explain why this would be of value, and how access/quality could be improved?

There is now a considerable number of geospatial datasets that are open access. However, the creation of a single, easier to use, Open Data Portal making it easier to find the available data and identify the most current versions would be extremely beneficial. For example, there are approximately 1,500 Environment Agency datasets on the data.gov.uk website so promotion or that and/or knowing how to find datasets would be useful.

There is also a considerable amount of data on the data.gov.uk website that is described but not actually released meaning we know the data exists but we do not have access to them. For example, **abstraction data**. There is a record on data.gov.uk for Abstracted

Surface Water Abstractions and for Abstracted Groundwater Water Abstractions, but neither datasets are released.

There is a real need for a nationally agreed standard habitat and land-use map. Without a good evidence base, we will always be vulnerable to making poor and incorrect decisions (see answer to question 12). In addition, greater consideration needs to be given to standard approaches to datasets collected and represented by county and local authorities so that these can be combined, used and interpreted across administrative boundaries.

There are also a number of areas where The Wildlife Trusts believe the Geospatial Commission should prioritise to target. These include:

- **Environmental data.** Providing easy access to spatial data that shows where our best areas for wildlife are could help speed-up the planning process. This needs to include information on legal obligations. Currently, there are big gaps in terms of quality and quantity of data available at local and national scales with the most detailed and accurate data held at a local level (for example, the NRN Atlas has many species records but it is low resolution national data on protected species compared to the high resolution, more geospatially accurate data held by Local Environmental Records Centres). Access to these more detailed and useful datasets could be improved by making funding available to support the organisations involved in collecting the data (in the same way that the Ordnance Survey requires security of funding for it to carry out its detailed mapping work).
- **Geological data.** Having access to good quality, open source geological data would be useful as an input into Nature Recovery Network, habitat creation and restoration opportunity, ecosystem services and natural capital mapping.
- **Public Rights of Way data**. This is held by local authorities and not always freely shared. However, to analyse the accessibility and recreational value of green spaces, this data is essential.
- **Aerial Mapping.** The Wildlife Trusts would welcome greater access to up-to-date aerial mapping as it is expensive and, quite often, long out of date. It is possible to use the aerial photo feature on Google, which are often better and a good source of information, but these cannot be interrogated in the same way in GIS.
- **OS MasterMap.** The Wildlife Trusts would really welcome full access to OS MasterMap as a desired end point. It would make much of our work, especially that with landowners and in the wider countryside, more efficient and accurate. At the moment, public sector organisations benefit from a Public Sector Mapping Agreements (PSMA) to access and share Ordnance Survey digital mapping. However, this PSMA does not extend to charities. Vector OS data is developing well but it would be useful if further features could be fully mapped.
- In terms of **artificial intelligence** data, the ability to map the movement of water (e.g. through channels in a reedbed) would be very helpful.
- Ensure that **shared European Union data** remains available in the UK after Brexit (e.g. the European Soil Database from the European Commission's Joint Research Centre).
- **Pollution Incident** data would be useful in targeting restoration projects and advice. There is some information on data.gov.uk but it is mostly older and limited in the amount of detail it contains. We appreciate that this might be due to

privacy issues relating to personal information but even knowing the type of incident (e.g. agricultural, domestic, industrial) would be beneficial.

If Government were to increase and improve access to the above Geospatial Data, the Wildlife Trusts would prefer to see this to develop as **Local Nature Recovery Maps** and to embed them in local plans. These accessible maps and plans would then guide decisions on housing and development to ensure they make a positive contribution to nature's recovery. They would also inform strategic decisions on the targeting of public funding for farming and land management, to maximise the positive impact on wildlife. And they would guide other forms of regulation and investment to maximise their effective contribution to nature's recovery.

In addition, this would also enable the current Government to achieve their commitment to ensure this new body "set the standards to digitise the planning process and help create the most comprehensive digital map of Britain to date"[1].

Q6: How should the commission be looking to develop the UK's capability in Earth observation data, both technologically and to support an effective market?

The Joint Nature Conservation Committee (JNCC) has been working on some Intermediate Product Satellite Data which takes the complexity out of satellite image processing, allowing a wider audience to access and use derived information. Intermediate Products derived from the European Space Agency Copernicus data sets (optical, radar and atmospheric-sounding satellite systems) will allow a robust long-term series of Intermediate Products to be created. However, this work now appears to have been paused or delayed.

[1] The Conservative and Unionist Party Manifesto (2017) *Forward, Together. Our plan for a Stronger Britain and Prosperous Future.*

Q9: What are the options for how public sector organisations could continue to invest in maintaining and enhancing our geospatial data assets?

A **spatial plan for the environment** would ensure public spending and investments result in well informed decision making that is better targeted, more effective and delivers multiple benefits. It would also enable better and faster decision making on housing and commercial development and infrastructure, by providing robust and easily available information on risks, opportunities and synergies to help plan land use and allocate development sites. It would **enable more efficient targeting of public, private and charitable funding in the urban and rural environment to contribute to nature's recovery**.

The Wildlife Trusts believe that local authorities should be required, with full support and funding from central government, to develop **Local Nature Recovery Maps** to achieve these objectives, and to embed them in local plans. Taking this innovative approach, these maps and plans would then guide decisions on housing and development to ensure they make a positive contribution to nature's recovery. They would also inform strategic decisions on the targeting of public funding for farming and land management, to maximise the positive impact on wildlife. And they would guide other forms of regulation and investment to maximise their effective contribution to nature's recovery. This approach would require the best available data and is dependent on mapping licenses and data from a variety of sources:

- identify and highlight the precise location and extent of our "core natural assets" (Sites of Special Scientific Interest, National Nature Reserves, Local Nature Reserves, Local Wildlife Sites, non-statutory nature reserves, etc. Marine Protected Areas, at sea);
- plot the known location and extent of priority wildlife habitats (including semi-natural ancient woodland);
- calculate the ecological connectivity between the existing components of the "core natural asset" network, and between networks of known priority habitat;
- combine this essentially wildlife/biodiversity information with other available social and environmental data that can be presented spatially (soil type, geology, hydrology/flood-risk, air quality, health statistics, etc);
- identify the location and extent of "restoration sites" where pro-active interventions to repair damaged and degraded habitats would enhance the ecological value, function and connectivity of the "core natural assets", and where this would be technically possible and politically desirable;
- plot out the boundaries of a wider "recovery zone" within which there is the greatest opportunity and need for poor quality existing habitats to be restored, for the existing "core natural assets" to be extended, buffered and linked, and for new wildlife-rich green and blue spaces to contribute to the wellbeing and prosperity of people;
- calculate and demonstrate the social and economic value of measures to protect, enhance, restore and create habitats in different parts of the Network.

However, as a consequence of public sector cuts, The Wildlife Trusts are aware of the impact these have had on local authorities as they have lost both ecologists and individuals with the skills and expertise to use and interpret both ecological and GIS data. Given how

much they depend on geospatial data, this is a considerable concern and should be addressed.

The public sector need access to up-to-date, locally informed data on which to base decision making. They should have a role in supporting this through either direct funding and/or through two-way data sharing agreements. There needs to be an increase in investment from public sector organisations to secure and maintain up-to-date local data and to support the integration of local datasets into national datasets. Many Wildlife Trusts have a good record in providing ecological geospatial data to local authorities, often through partnerships to share the costs of maintaining ecological data.

Q11: What role should the private sector have in both the development and maintenance of the underpinning infrastructure and enhancing the UK's geospatial data assets?

The private sector has a crucial role in both the development and maintenance of enhancing the UK's geospatial data assets.

The private sector does need to pay for geospatial data that has a commercial benefit and that has been collected using taxpayers' money or charitable resources. For example, Local Environmental Records Centre (LERCs) hold vast datasets on species and habitats across the country. Currently, most of them do not charge for data but instead charge for the time it takes to collate the data and format reports. Ultimately, it costs LERCs to collect, manage and provide data. The costs need to be borne by partners or recovered (either commercially, through public sector funding etc). Currently, commercial enquiries provide good income for most LERCs. This helps fund staff time to collate and update data for protected species through liaison with recorders, field world and data extraction.

In addition, any geospatial data gathered by private companies should be shared a certain time after its commercial use. Businesses and developers should also contribute to high quality datasets so that more information is available ahead of the planning application process. This would reduce the need for surveys and potentially speed up the decision-making process. For example, Natural England is currently developing a District Strategic Licensing approach for Great Crested Newts (GCN). This approach would assess the degree of risk posted by development to GCN populations. This baseline risk, in light of current GCN distribution modelling, would be mapped and developers would pay a tariff that would vary depending on whether the proposed development was in a very high, high, medium or low risk area. Developers and businesses should be helping to resource the high quality datasets required.

We also believe that data collected by statutory agencies should be shared with non-profit companies and charities, preferably through Local Environmental Records Centres. Again, this doesn't happen routinely and it can be a challenge to access data from Natural England.

Q12. Do you face challenges when working with geospatial data from across the public sector? If so, what are they and how could value be better released? Are there any technical remedies or standards that could be adopted to improve the interoperability of geospatial data? Please provide supporting evidence of what these remedies could help to accomplish.

The Wildlife Trusts do face issues trying to use Ordnance Survey data and licenses. OS say that data digitised to one of their base maps can only be given to those with the same base map licence. It they could change the rule so that the organisation producing the layer needed to pay for the licence and those just displaying it didn't, that would make data considerably more shareable. At the moment, public sector organisations benefit from a Public Sector Mapping Agreements (PSMA) to access and share Ordnance Survey digital mapping. However, this PSMA does not extend to charities. The Wildlife Trusts would really welcome full access to OS MasterMap as a desired end point.

The Wildlife Trusts are able to access some public-sector data (e.g. layers from Highways England about routes of new roads). In addition, some Wildlife Trusts have entered into data sharing agreements with Local Environmental Records Centres to get habitat mapping, species records etc. But, this approach is not uniform across the country and the quality and availability of data, especially habitat mapping, varies greatly. For example, some parts of the country do not have Phase 1 habitat mapping. Just providing that to the same standard nationally would be extremely beneficial.

As part of their Habitat Network Mapping Project, Natural England has produced a series of maps. They are still under development, but we are aware that some are beginning to be used. However, we have concerns about the maps and the underlying datasets being used. Natural England has, so far, just used their national Priority Habitat Inventory (PHI) datasets. However, for some habitats and locations, this data is wrong. For example, the Hertfordshire and Middlesex Wildlife Trust has compared the NE Priority Habitat Inventory (PHI) to the Hertfordshire Environmental Records Centre (HERC) data. For Lowland Heathland, the NE PHI identifies a considerably larger area of lowland heathland than HERC habitat mapping for a number of reasons including:

- At Croxley Moor Common SSSI, the NE Priority Habitat has the area incorrectly attributed to heathland when it is acid grassland. Even the NE SSSI condition report (Jun 2014) records the site to be acid grassland but the Priority Habitat Inventory has not been corrected.
- At Rail Copse, most of entire site is included on the ancient woodland inventory (and aerial photography shows it does not contain clearings) yet it is included on the NE Priority Habitat as lowland heathland.

Natural England has acknowledged that local data needs to be included to make them more relevant to a local area. But, the public sector has to provide resources if it wants data ground-truthing and monitored. NGOs cannot and should not be expected to do this for Government for no cost.

Some local authorities do not have access to Local Wildlife Site data or information on protected sites data. However, this is required to perform their statutory duty under the Natural Environmental and Rural Communities Act (2006). However, the biodiversity duty has been described by a House of Lords Select Committee as "ineffective as it stands, as a result of limited awareness and understanding among public bodies, weak working

and the lack of clear reporting requirements and enforcement measures"[4]. As a result, Local Authorities (and public bodies) consider the lack of this data as low risk and choose not to fund its provision.

These challenges need to be addressed and resolved if Government is to meet its commitment in the 25 Year Environment Plan[5], to "develop a Nature Recovery Network providing 500,000 hectares of additional wildlife habitat, more effectively linking existed protected sites and landscapes, as well as urban green and blue infrastructure.". A Nature Recovery Network is a **joined-up natural system of places important for wild plants and animals, on land and at sea**. This network of interconnected wildlife-rich places allows ecological processes to function. It includes all the places where these processes contribute to flood-risk management, carbon storage, improved air quality, water purification, outdoor recreation, community cohesion, cultural inspiration, education, health and wellbeing. It brings value to people.

This **spatial plan for the environment** would ensure public spending and investments result in well informed decision making that is better targeted, more effective and delivers multiple benefits. It would also enable better and faster decision making on housing and commercial development and infrastructure, by providing robust and easily available information on risks, opportunities and synergies to help plan land use and allocate development sites. It would **enable more efficient targeting of public, private and charitable funding in the urban and rural environment to contribute to nature's recovery.** But, it relies on having access to up-to-date, comprehensive environmental geospatial datasets.

Q13. How can the Geospatial Commission act as a more effective customer for geospatial data on behalf of the public sector?

The creation of a single, easier to use, Open Data Portal making it easier to find the available data and identify the most current versions would be beneficial. For example, there are approximately 1,500 Environment Agency datasets on the data.gov.uk website.

There is also a considerable amount of data on the data.gov.uk website that is described but not actually released meaning we know they exist but do not have access to them. For example, abstraction data. There is a record on data.gov.uk for Abstracted Surface Water Abstractions and for Abstracted Groundwater Water Abstractions, but neither datasets are released.

Q14. Are there any additional geospatial datasets, from the other partner bodies or other sources, that the public sector would derive significant benefit from having access to, that might have novel and valuable use cases? What would that access look like?

[4] House of Lords (2018) *The Countryside at a crossroads: Is the Natural Environment and Rural Communities Act 2006 still fit for purpose?*
[5] HM Government (2018) *A Green Future: our 25 Year Plan to Improve the Environment*.

The Wildlife Trusts believe that local authorities should be required, with full support and funding from central government, to develop **Local Nature Recovery Maps** to achieve these objectives, and to embed them in local plans. Taking this innovative approach, these maps and plans would then guide decisions on housing and development to ensure they make a positive contribution to nature's recovery. They would also inform strategic decisions on the targeting of public funding for farming and land management, to maximise the positive impact on wildlife. And they would guide other forms of regulation and investment to maximise their effective contribution to nature's recovery. It would also **enable investment into natural capital** intended to enhance the provision of ecosystem services to generate cost savings, commercial income and/or investment returns.

To support this, public bodies would also benefit from there being a Nature Recovery Network map as, amongst other things, it would highlight where lack of access to nature is exacerbating health deprivation, where environmental features are delivering ecosystem services, where resources targeted to deliver parts of the NRN would deliver many public benefits.

This approach would require the best available data and is dependent on mapping licenses and data from a variety of sources:

- identify and highlight the precise location and extent of our "core natural assets" (Sites of Special Scientific Interest, National Nature Reserves, Local Nature Reserves, Local Wildlife Sites, non-statutory nature reserves, etc. Marine Protected Areas, at sea);
- plot the known location and extent of priority wildlife habitats (including semi-natural ancient woodland);
- calculate the ecological connectivity between the existing components of the "core natural asset" network, and between networks of known priority habitat;
- combine this essentially wildlife/biodiversity information with other available social and environmental data that can be presented spatially (soil type, geology, hydrology/flood-risk, air quality, health statistics, etc);
- identify the location and extent of "restoration sites" where pro-active interventions to repair damaged and degraded habitats would enhance the ecological value, function and connectivity of the "core natural assets", and where this would be technically possible and politically desirable;
- plot out the boundaries of a wider "recovery zone" within which there is the greatest opportunity and need for poor quality existing habitats to be restored, for the existing "core natural assets" to be extended, buffered and linked, and for new wildlife-rich green and blue spaces to contribute to the wellbeing and prosperity of people;
- calculate and demonstrate the social and economic value of measures to protect, enhance, restore and create habitats in different parts of the Network.

This **spatial plan for the environment** would ensure public spending and investments result in well informed decision making that is better targeted, more effective and delivers multiple benefits. It would also enable better and faster decision making on housing and commercial development and infrastructure, by providing robust and easily available information on risks, opportunities and synergies to help plan land use and allocate

development sites. It would **enable more efficient targeting of public, private and charitable funding in the urban and rural environment to contribute to nature's recovery.** But, it relies on having access to up-to-date, comprehensive environmental geospatial datasets.

Q16: How can we best ensure effective local authority coordination and sharing of best practise, using location data to better deliver public services?

In the Government's 25 Year Environment Plan[6], they committed to "develop a Nature Recovery Network providing 500,000 hectares of additional wildlife habitat, more effectively linking existed protected sites and landscapes, as well as urban green and blue infrastructure" and that "we will develop maps and advice to show where actions to improve and restore habitats would be most effective".

A Nature Recovery Network is a joined-up natural system of places important for wild plants and animals, on land and at sea. This network of interconnected wildlife-rich places allows ecological processes to function. It includes all the places where these processes contribute to flood-risk management, carbon storage, improved air quality, water purification, outdoor recreation, community cohesion, cultural inspiration, education, health and wellbeing. It brings value to people.

The *Making Space for Nature* report[7] (2010) made a very strong case for a different approach to nature conservation in England. The Report concluded that England's wildlife sites that currently make up our protected area network are too small, too fragmented, too few in number and not managed well enough.

Work done by the Natural Capital Committee, chaired by Professor Dieter Helm, demonstrated that the social and economic value of a healthy, ecologically functioning network of places that are rich in wildlife would be extremely high. For example, there is a large and growing body of evidence that improvements in the natural green and blue space in and around our most disadvantaged neighbourhoods would bring the greatest social benefit from a health and wellbeing perspective.

A geospatial approach is essential to realising this vision. It matters where new habitats are created and how they related to existing wildlife sites. It matters how plants and animals move around the landscape and how networks of natural greenspace join our towns, cities and urban neighbourhoods to each other and to the wider countryside. All those with a stake in nature's recovery need to share a common understanding of what

[6] HM Government (2018) *A Green Future: our 25 Year Plan to Improve the Environment*.
[7] Lawton J. *et al* (2010) *Making Space for Nature: a review of England's wildlife sites and ecological network*.

needs to be done in real places. We believe that nature's recovery will only work if there is a statutory requirement to map nature's recovery and all parts of Government are required to contribute to the development, maintenance and implementation of spatial maps.

These maps and a clear spatial plan can then be used to ensure the necessary investments and public spending (e.g. public health spending, agri-environment payments) are targeted in the right places to maximise the environmental, social and economic benefits. Through collaboration, this will help realise multiple benefits in real places. For example, it enable better and faster decision making on housing and commercial development and infrastructure, by providing robust and easily available information on risks, opportunities and synergies to help plan land use and allocate development sites. The maps could also be used to support the improvement in public health by increasing regular access to nature for all. Natural England has estimated that if every household in England were provided with good access to quality green space (enabled in future by creation of a Nature Recovery Network), it could save an estimated £2.1 billion in healthcare costs[8].

We believe **Nature Recovery Maps** (to support the Nature Recovery Network) need to be "owned" by long-standing, stable public bodies with a wide range of existing duties and responsibilities. They would need to be owned by local stakeholders and based on high quality data mapped to a high degree of precision, and to benefit from significant support and input from a wide range of public bodies and other organisations. To us, **Local Authorities are the obvious bodies to take on the task of producing and 'hosting' the maps, bring together all the other significant stakeholders.**

The Natural Environmental and Rural Communities Act (2006) placed a duty on public bodies to have regard to biodiversity. However, many have down-played and under-valued this duty and it has demonstrably failed to prevent the continued loss of biodiversity related to the business of most public bodies. Local authorities do not have joined-up mapping systems that are regularly updated and used by all staff and are not currently required to map planning application footprints and then the actual land areas developed. If this information was captured and then shared, cumulative impacts could be better taken into account.

Nature's recovery will only happen when public bodies are required to use effective tools (including spatial mapping) to support their activity. **We believe the duty on public bodies should be strengthened to include contributing effectively to the development, maintenance and delivery of Nature Recovery Maps and plans**.

Q17: As a result of this analysis, we are prioritising the exploration of possible initiatives in the high-value categories identified:

- **property and land**
- **infrastructure and construction**

[8] Natural England (2009). Technical Information Note 055 – 'An estimate of the economic and health value and cost effectiveness of the expanded WHI scheme 2009'

- **mobility**
- **natural resources**
- **sales and marketing**

What are the existing or potential geospatial applications which could be scaled-up or developed in order to capture economic value? (We would particularly welcome responses from industry and other bodies engaged in these sectors.)

A **spatial plan for the environment** would ensure public spending and investments result in well informed decision making that is better targeted, more effective and delivers multiple benefits. It would also enable better and faster decision making on housing and commercial development and infrastructure, by providing robust and easily available information on risks, opportunities and synergies to help plan land use and allocate development sites. It would enable more efficient targeting of public, private and charitable funding in the urban and rural environment to contribute to nature's recovery. The existence of such maps would bring benefits in the improved targeting of advice and other effort related to a number of central government strategies (such as the National Pollinator Strategy). It could contribute to cost reduction in various public-sector areas, for example by aligning green infrastructure provision with those areas suffering from health inequalities, and by informing rural and farming subsidies to secure the most effective delivery of public goods. By combining environmental and social data this mapping will benefit businesses, the public sector and the environment sector, helping to plan and locate activities and projects in a way that will deliver better outcomes and give the highest return on investment, whilst having a net positive impact on the environment. **This approach would benefit all high-value categories** identified in the Call for Evidence document but especially property and land, infrastructure and construction, mobility and natural resources.

The role of Nature Recovery Maps in providing specific spatial focus would enable more **effective and efficient investment of "environmental net gain" funding from developers**. In addition, the National Infrastructure Commission is tasked with identifying strategic infrastructure needs that would enable significant opportunities for economic development. As part of work on a Nature Recovery Network and a framework for a national ecological network map, The Wildlife Trusts are in the process of piloting this mapping approach for the proposed Oxford to Cambridge Expressway and associated development. The map could then be used to target infrastructure and investment and ensure that the associated housing, commercial development and infrastructure development contributes positively to nature's recovery. The approach and spatial data sources required is set out in more detail in Question 14. The proposed mapping approach can be easily scaled up or down or 'cut' for different geographic areas.

If the Government is to deliver the agenda set out in the Housing White Paper, the 25 Year Plan for the Environment and to meet its ambition to be "*the first generation to leave the environment in a better state that it found it*" it will need to ensure that housing and related infrastructure is delivered in a way that delivers a net gain to the natural environment and enhances natural capital. Development should retain and enhance nature's ability to deliver a host of services, such as flood water storage, water resource

management, and pollution reduction, and provide homes with access to nature to promote health and wellbeing. This can only be achieved by taking a spatial approach, using the best available geospatial datasets, to planning and implementing Major Infrastructure Projects. These maps would allow nature's recovery to sit alongside economic development as a legitimate purpose for the planning and development system.

Call for evidence - three key themes

We have identified three high-level themes that could help our approach to setting a strategy which are as follows:

1. **Supporting innovation in the geospatial sector**, exploring how to secure cutting edge skills, the right access to data, and opportunities from emerging technologies for the geospatial sector itself
2. **Enhancing the UK's geospatial assets,** looking at how best to align interests, avoid duplication, and instill best practice across the whole public sector
3. **Driving investment and productivity in geospatial applications**, asking in which wider sectors the most value lies from better exploitation and use of geospatial data, in the UK and internationally

Our questions

Q1. Is our view of the geospatial data types accurate? If not, what should be included or excluded from this?

The definitions as shown are slightly confusing.

Geospatial data – "place" brings connotations of a place, literally. Suggest you change place to location

Positional data for me is literally the coordinates that define a precise location e.g. GPS coordinates, map coordinates and so on. Falls under geodesy/geodetic data.

Geospatial identifiers – identifies a unique object by means of a reference ID that can be associated to a geospatial data feature, thereby linking non spatial data to geospatial data

Geospatial services – these are not data types per se. Geospatial services to me refers to the various protocols for publishing and sharing geospatial data as web services.

In summary, for me, you have the underlying coordinate referencing system that allows you to precisely define position. Positional data refers to the coordinate data that identifies the precise location of the geospatial data – those real world features and objects where location is a key feature of its source and/or use. Using geospatial identifiers for these features and objects allows you to then link non-spatial data to these geospatial features and across different business

systems.
Collections of geospatial features can be published as web services e.g. individual datasets or data layers.

Defining “Linked Data” would be worth adding.
And you may want to consider the distinction between datasets and data layers.

I also think providing some examples against each definition would be helpful to illustrate the point.

Q2. In addition to current government policy, what are the areas of geospatial skills where the commission could best focus, to help ensure the necessary capability within the UK for the future?

Digital skills need to start from school onwards – geospatial skills are slowly becoming better established in primary/secondary schools but there’s a lack of current knowledge and insight from teachers. We need to provide better resources to support teachers and be better at integrating digital skills into the curriculum and within that, ensuring that geospatial skills are incorporated. This could be an opportunity for greater industry/education collaboration – identifying best practice and applying that in a more consistent manner across the board.

I am also aware that at graduate and postgraduate level teaching today, much of the material and focus is out of date – the pace of change is rapid and universities often don’t have the time to keep abreast. Also, we tend to proliferate teaching on one specific GIS software suite (ESRI) and this should be complemented with better access to and support of the excellent range of open source geospatial technologies, cloud computing resources etc. that are available.

There is a greater than ever convergence taking place between mainstream IT and GIS so topics like software engineering, coding, cloud computing, data science, data analytics, sensors/IoT etc. need to be much more to the fore. We’re also witnessing the emergence of AI and ML – these will have ever greater resonance within the geospatial world and we need to start laying the skills down in these areas.

Initiatives like Codebase, Codeclan, CENSIS and DataLab in Scotland all provide avenues where geospatial skills could and should be incorporated – such that geospatial becomes much more mainstream in the DNA of our digital economy.

It’s all about the data – we tend to overlook the importance of good data governance and the fundamentals of data management – these skills are more important than ever. We can have the best technology in the world, but need to ensure the data is fit for purpose – I still see a lot of poor quality data collection and maintenance and we need to educate both those responsible for data collection, creation and maintenance in good practice and importantly, educate middle, senior and executive levels on the importance of data as an asset that

needs to be managed like any other asset.

Q3. What are the geospatial skills needs and gaps in your organisations, how can these be most effectively addressed, and how can careers in the sector be best promoted?

Within thinkWhere we've transformed from a "traditional" GIS consultancy to a GIS software and technology business. We've introduced agile Scrum methodology, DevOps processes and procedures for software development and enterprise architecture skills for platform design and cloud computing. These were all new and very different from the "traditional" skills our GIS developers used to have. These are skills that will continue to grow in importance as we look to the future.

At present it's very rare to find individuals who have these software engineering and coding skills as well as the core GIS skills. As mentioned in Q2, more could be done in the university curriculum and more could be done via technology incubation services and innovation centres, via digital skills and coding academies, via college digital and creative skills courses etc. to raise the awareness and understanding of geospatial.

Big data, data science and data visualisation are also key skills that are going to grow in demand and we need to see much stronger cross-fertilisation between geospatial and these related fields to develop the combined skills needed for geospatialists of the future.

We need to look at better ways of preparing the next generation with the digital and geospatial skills required in a future where geospatial data will be omnipresent. To date, we've been too introspective, there needs to be greater industry/education/academia collaboration, stronger collaborations with related industries and professional bodies in these sectors etc. If we look at the prominence that BIM has achieved over the last 3-5 years, we should be able to do this and more for geospatial!

I also think we could be doing a lot more to raise awareness and understanding of geospatial as part of economic development strategies – we need to elevate recognition within local and central government and with economic development agencies as to how essential geospatial is to the future of society, the economy and the environment. At present, geospatial is either assumed to be about maps or isn't understood at all. Creating better awareness and aligning the contribution geospatial can make to social, environmental and economic outputs and outcomes will stimulate more demand.

Q4. Are there any publicly or privately-held geospatial datasets that are currently challenging to access or use or of insufficient quality, but which you or your organisation would find valuable if these issues could be resolved? Please explain why this would be of value, and how access/quality could be improved?

Depends how radical we want to be. Arguably, all geospatial data collected by government departments and agencies at the taxpayer's expense should be made openly available – this would create a massive stimulus to use and reuse of the data, unlocking economic value in new and unimagined ways. This would require such significant structural change and long term timescales that it is more a pipe dream!

The role and status of the Big 6 should be clarified as to the work they do as part of the "national good" versus that which is commercial – using OS as an example, as a government owned company they are now effectively competing with their partners in the market. The more we prime OS with additional government funding to either do things they should have done already (i.e. open data publication for INSPIRE) or funding to start providing new/additional services that compete with their partners, the more confusing the situation becomes. Partial opening up of datasets such as OSMM exacerbate the situation – hooking customers to a service that they then need to pay for, creating revenues for OS and potentially making it more difficult for partners to provide competitive services. We need real clarity to have confidence that it is a level playing field and not an anti-competitive situation, benefitting from State Aid.

Licencing is still a major headache for end users of data – there are many different licences in use, licences can be complex, difficult to understand or apply, providing a real barrier to the uptake and use of geospatial data. This area needs simplification and standardisation. OS licencing is particularly onerous – although it has been "simplified" over the last few years, most of our clients do not understand it and it proves to be a real barrier to uptake and use of their data.

We also need to make sure we take a wide look at the geospatial data landscape – it's not just about the Big 6. There are many more public sector producers of geospatial data – at local, regional and national levels and it's important that the Commission looks to this wider landscape of geospatial data to identify and support initiatives for improvement in use, access etc.

In terms of specific datasets that are difficult to access – some of the key ones would be flooding data (SEPA), land titles (RoS and HMLR), LiDAR (Scotland), nationally consistent planning data and importantly **all** utility datasets – these are traditionally very difficult to source yet essential to all development projects across the country. Ideally, these datasets should all be made available via APIs as online web services, with the option for data download.

Although there has been a big push on local and central government to open up

their data, and a lot of the focus has been on geospatial data, it's still difficult to find the data and, more importantly, to find out when it was last updated or changed. We have a plethora of geoportals or data portals at local, regional and national levels and we need to simplify/make it more transparent for end users where and how to find geospatial data of interest and how to find out if and when it's been updated. Most of our commercial clients employ full-time resources to undertake this task – a very inefficient use of resources, many times over.

Q5: Do you anticipate that any changes will be needed to the both address data and the wider address ecosystem, to support emerging technologies? Please provide evidence of value to support any proposed changes.

Standardised, structured addresses – made openly available – with shared unique identifiers would be a game changer across the public sector and private sector alike. However, I've seen the ongoing "battles" between OS, Royal Mail and local government played out over the last 20 years and we still don't seem much closer to a resolution for open addresses. I think real structural change would be required to make a difference.

Whilst addresses are fundamentally important to service operation and service delivery across a wide range of public and private sector functions, we also need to look at how we consistently and intuitively reference non addressable buildings, features and locations. For example, as we deploy IoT sensors, they will very often be in non-addressable locations – the same can be said of wind farm turbines, solar arrays and so on. We need to have a simple, easily understood method for non-addressable referencing – people still get confused by grid coordinates. What3Words is one attempt at removing the complexity and may be worth further consideration.

We also need to think about the third dimension in addressing and how we uniquely locate features and objects in 3D space – this is going to become increasingly important.

Q6: How should the commission be looking to develop the UK's capability in Earth observation data, both technologically and to support an effective market?

Earth observation data will play a very significant role across many different industry sectors. At this stage, there is an awareness gap in the UK on what data is available and what you can do with it. Developing the UK's capability therefore needs to include education and awareness – with demonstrator/pilot projects to show what can be achieved.

Through a combination of application ready EO data and AI techniques, there is

strong potential to save costs, to improve decision-making and to potentially export the skills, knowledge and expertise to a wider global market.

We also need to be training and equipping graduates and others in the workforce with the requisite skills to manage and use EO data and practically translate its application to tangible business benefits.

For public services, in the same way that framework agreements have been established for OS data, it would be advantageous to establish something similar for EO data, thereby avoiding overlapping and duplication of costs/effort, introducing economies of scale and creating a stronger, collaborative community of interest.

Q7. Which new technologies should the commission focus on to provide new opportunities to process and exploit geospatial data for economic growth?

There is a wide spectrum of maturity in the use of current technologies for geospatial data and services. The use of cloud computing, harnessing/driving the improved use of cloud native technologies, API's and web services is still, for many in the market, very new. We need to continue to push the benefits and opportunities of service-orientation, interoperable API's and data standards to maximise the potential for streamlined and efficient use of geospatial data and services.

We need to encourage government data publishers to make their geospatial data available via open, documented APIs and improve the mechanisms to catalogue and search for these services.

We need to strongly advocate and encourage open standards throughout and work with the GIS industry to ensure the adoption of these standards is established.

We need to more proactively promote the benefits and opportunities of open source geospatial technologies – these are now mature solutions that provide flexibility and a growing community of interest for knowledge sharing and innovation in solutions.

Increasingly, integration is going to be one of the big keys – geospatial does not sit in isolation but as part of an organisations wider information environment. Easy and straightforward ability to plug in geospatial data, web maps etc. to other business systems and applications is essential.

Q8. How can geospatial data and applications be used to support enhanced roll-out of future technologies?

The planning, design and appraisal of technical and business options for investments such as 5G, IoT networks, electric charging point networks, renewable energy etc. all require a significant degree of spatial planning – developing models that integrate a wide range of geospatial and non spatial data to determine optimal locations and/or routes for these core future technologies.

Agri-tech, smart cities and new technologies in logistics are all directly enabled by the application of geospatial data.

As we look to a future world of autonomous vehicles, these will be highly dependent on precise, detailed location-based data to provide the digital twin/real world representation that they need to operate. Many car manufacturers are now investing heavily in digital mapping technologies to collect and maintain the underlying data – and generally to a higher specification than that of the equivalent public datasets.

The UK's economic growth will be underpinned by geospatial data and services and it's essential that we elevate the profile of the value and contribution.

We should be looking to Innovate UK and the various catapults as a driver for where/how geospatial could/should fit into future technologies and wider market sectors. Innovate UK and the UK Innovation Centres would also provide a great platform to publish and manage geospatial competitions and opportunities – making best use of the prime funding for the Commission.

Q9: What are the options for how public sector organisations could continue to invest in maintaining and enhancing our geospatial data assets?

On the one hand, the geospatial data collected by the public sector is collected for an existing purpose – maintaining and enhancing this data should really just be done as part of an inline process. On the other hand, recognition of the importance of data management and data as a key business asset is highly variable, often leading to substandard data quality. Further, the specification of geospatial data collected to meet an in house process may not ideally suit the wider market and internal funds to extend or improve it for purposes beyond that which it is being collected for is a hard argument – especially with public services under a constant budget squeeze.

Public bodies should be committed to maintaining and developing the core geospatial data they need to fulfil their business processes – formalising what should be happening already. Where there are needs that go beyond this, consideration could be given to funding these enhancements in the same way that OS and other large national departments/agencies receive government funding to improve and develop its products.

The model used by the PSMA in Australia could be worth considering – datasets that have wider commercial value are licenced commercially with a revenue return to the contributing organisations. However, establishing such an arrangement across the hundreds of local government organisations would be a long term challenge – it's already taken years just to get to the point where addresses and streets are becoming available under such a model.

This approach also raises the conflict between open data, data that is free at the point of use 'v' commercially licenced datasets.

Businesses will pay for value-added, consistent, complete data that can be relied upon.

Q10: What areas of the underpinning geospatial infrastructure such as positioning technologies, including GPS and indoor positioning systems, and geodetic networks and frameworks to support them, should we be prioritising the development of, in order to support the emerging requirements for geospatial data?

On a broader scale, we still suffer from broadband hotspots across the country, making it difficult if not impossible to access web mapping and GIS on the go. A lot of our clients go to lengths to find workarounds for offline geospatial data and digital mapping. Ideally we need 100% network coverage of super/ultra fast broadband to support frictionless use of geospatial data and services.

One of the next big things will be IoT networks – the Scottish Government has very recently approved £6m towards a LoRa network. As we move towards smart cities and a sensor driven world, using location to view, analyse and model sensor data in real/near real-time will be an increasing priority.

Q11: What role should the private sector have in both the development and maintenance of the underpinning infrastructure and enhancing the UK's geospatial data assets?

We need to first determine what are the "core reference geographies" – those geospatial datasets that form the foundations of the UKs spatial data infrastructure and should be developed and maintained by the public purse. We should also map and define the geospatial data collected as a result of legislation, regulation or other statutory requirements (e.g. list of roads/highways), again data that should be developed and maintained by the public purse.

There is a key role for the private sector to then use these core datasets to create added value products and services – this is where the market will drive innovation and competition, creating and unlocking new economic value. We need to make

sure that the public bodies, including the Big 6 have a clear delineation between these public purposes for developing and maintaining core geospatial data and the prospective commercial operations of the same organisations.

With the rise in autonomous vehicles we are going to find increasingly detailed street networks and street asset datasets that go well beyond the content specifications of the OS. In an ideal world you would like to see the real/near real time change intelligence being collected by the car manufacturers feeding its way back to the relevant public authorities – local government, highways authorities and OS etc. to complement the core reference data rather than repeat the same/similar data collection under public auspices.

Public/private collaborations or joint ventures could be bigger in the future – the public bodies bringing their extensive geospatial data knowledge and experience together with commercial partners to extend the scope and content of new or value added geospatial data and sharing in the resulting revenues.

We should also look at the alternative business models adopted by the likes of Uber, Mapbox etc. and see what we can learn and apply to do things differently in the geospatial industry in the UK.

Q12. Do you face challenges when working with geospatial data from across the public sector? If so, what are they and how could value be better released? Are there any technical remedies or standards that could be adopted to improve the interoperability of geospatial data? Please provide supporting evidence of what these remedies could help to accomplish.

Yes – the key challenges include :

Sourcing data – especially in local government. Data can be published on public websites, geoportals or not at all and can rely on knowing who to contact and what to ask for.

Quality and consistency – again, especially in local government where, beyond addresses and streets data, there is little in the way of common standards agreed for the many geospatial datasets created by Councils.

Aggregated datasets – a lot of our clients require regional or national level datasets from local government – there are very few nationally aggregated datasets currently available.

Change management – it is very difficult to determine if/when a published geospatial dataset has changed – the minority of public sector publishers make this information available, sometimes providing a helpful RSS feed. However, in most cases this information is not provided and we/our clients spend a lot of time

and effort checking multiple different websites to compare with the current data. This is highly counterproductive.

Improved, but minimal, metadata would help along with adoption of consistent practices for publishing data and use of catalogue services.

Q13. How can the Geospatial Commission act as a more effective customer for geospatial data on behalf of the public sector?

The Geospatial Commission needs to be completely independent of the Big 6 and objectively determine the problems, needs and challenges faced by the wide range of public sector consumers of geospatial data – clearly understanding the outputs and outcomes that the data is needed to support. This perspective should draw out the core geospatial data requirements, mapping these against the current offerings to provide an informed and meaningful analysis on where/how these geospatial data needs are best serviced, where the key gaps are and where interventions may be required.

We need to avoid, as far as practical, falling into the trap of just doing more of the same or similar, playing at the edges and not being bold enough to consider new and different ways of creating and delivering the geospatial data that meets the current and future needs of the public sector. This may mean a much greater degree of data, system, process or organisational integration between the core data suppliers (which are not just the Big 6 listed as Scottish and Welsh devolved departments and agencies are just as vital a part of the mix).

We also need to look at private sector capabilities and offerings – it may be more cost effective to pay for new/enhanced geospatial data rather than invest in the public sector bodies to do what the private sector may be able to do quicker and cheaper.

With the public sector being a very broad landscape, consideration should be given by the Commission as to the best way of representing these wide and varying use cases.

Q14. Are there any additional geospatial datasets, from the other partner bodies or other sources, that the public sector would derive significant benefit from having access to, that might have novel and valuable use cases? What would that access look like?

Not sure what is meant by this question and why the focus is solely on the public sector?

A lot of the untapped social, economic and environmental benefits will arise from the private sector – there are great innovations, applications and uses of geospatial data in retail, insurance, logistics etc. and we should be looking outwardly to these sectors for inspiration and opportunity.

For example, Glenigans and Barbour both compile national planning datasets from the many public sector sources – this national dataset would be immensely valuable and useful to the public sector itself. Should we be considering creation of the same/similar dataset within the public sector or collaborating with a private sector partner to achieve this?

Q15: How can we best develop a single UK strategy, ensuring alignment between the individual strategies across the UK while still allowing for regional variations?

We need to have a clear objective on the scope and purpose of a single UK strategy. Why do we need a strategy, what elements of the strategy are truly UK wide e.g. core reference geographies, versus what elements are not e.g. where different legislation or regulation applies etc.

We need to understand what geospatial strategies are already in place at the national, devolved and regional administration levels. Looking for good/best practice, stage of maturity in strategy delivery etc.

We also need to look wider afield to best practice approaches for geospatial strategies across the world e.g. the United Nations Committee of Experts on Global Geospatial Information Management to ensure that the strategy considers all the dimensions that collectively make up an effective strategy – people, process, data and technology – with a clear focus on objectives and outcomes.

We need to ensure we look beyond the traditional users and uses of geospatial data – previous strategies have tended to look inwardly too much and focus on the public sector and public sector data. We should be looking at the private sector a lot more where there are innovations in the application and use of geospatial data and services.

We also need to align the geospatial strategies much better with other, related strategies and initiatives e.g. UK Industrial Strategy, Govt Construction Strategy, Scotland's Programme for Government and Digital Strategy etc. to broaden the appeal and recognition of the importance of geospatial to delivery of these.

Careful consideration will be needed on the governance arrangements during

strategy development – ensuring the devolved and regional administrations are adequately represented and have a meaningful voice at the table.

Overall, the regional and devolved spatial strategies should be key building blocks of the UK wide strategy – ideally integrating these with one vision and with aligned delivery objectives and priorities.

Q16: How can we best ensure effective local authority coordination and sharing of best practise, using location data to better deliver public services?

Over the last 5-10 years we have seen a significant development and improvement in the use of GIS and location data by local authorities – as part of Channel Shift, Citizen First etc. web mapping and online spatial searches etc. are now used by most Councils as part of their self-service offering to the public. SOCITM has been a key driver in advancing this.

However, local authorities are still not unlocking the full potential of their geospatial data and there are numerous opportunities to improve public engagement and service delivery with innovations like 3D and augmented reality for planning applications etc.

There's still a sense that, at a strategic level, the importance of geospatial is still not fully recognised – local government leaders e.g. SOLACE, Digital Leaders groups/forums all need to be better exposed to the benefits and opportunities of using location data for public service delivery and excited by the art of the possible with the most recent technologies – going beyond the basics of "where's my nearest" or "how do I get to" and into "what if" and a more interactive form of public engagement powered by geospatial.

There are already numerous communities of interest within and across local government – GeoPlace, the Improvement Service, COSLA, Local Govt Association, various forums, Knowledge Hub etc. that provide a degree of coordination and sharing of best practice.

Consideration to funding a suite of new, innovative demonstrator projects as touched on above could be a very useful tool to entice awareness and interest on the new possibilities. Equally, initiatives like CivTech, GovTech and local government open data challenges (ODI) would help to develop new ideas, share good practice and stimulate opportunity.

Q17: As a result of this analysis, we are prioritising the exploration of possible initiatives in the high-value categories identified:

- **property and land**

- **infrastructure and construction**
- **mobility**
- **natural resources**
- **sales and marketing**

What are the existing or potential geospatial applications which could be scaled-up or developed in order to capture economic value? (We would particularly welcome responses from industry and other bodies engaged in these sectors.)

Not entirely sure what is meant by this question.

Digital engineering and the integration of GIS and BIM for infrastructure and construction
Compilation, publication and access to national registers of vacant, derelict and brownfield land
eConveyancing

Q18: Are there any other areas that we should look at as a priority?

Renewable Energy
Healthcare
Agri-tech
Insurance
Retail
Disaster Management and Emergency Response

Q19: What are the main potential private and public sector innovations that will rely on the use of geospatial data to rollout, and are there corresponding regulatory challenges?

Autonomous vehicles will have a huge reliance on geospatial data with a richer content specification and higher degrees of accuracy.
Smart cities and the expansion of IoT sensors into all walks of life – generating huge volumes of data about people, place, movements and events.

Q20: How best can we make the UK's presence in the international geospatial world more visible?

We need to showcase existing good/best practice and make it easy to discover and access these resources online – ideally through a single gateway rather than having to search multiple sites to find the resources.

We need to proactively promote our activities and increase our profile at international events.

We need to establish/build on connections with groups such as the Group on Earth Observations.

We need to look for opportunities for knowledge and experience sharing with international partners and colleagues using existing networks.

We need to look for collaborative project opportunities whereby we can involve ourselves in global projects and initiatives.

We should look at the opportunities to work with our development agencies international arms (e.g. SDI in Scotland) to explore opportunities for international promotion, trade visits etc.

Q21: Where should the UK be looking for points of comparison overseas? Who are the other international exemplars? What best practice is being modelled overseas that we can learn from?

The USA for their NSDI and landmark geospatial policies
PSMA Australia
e-Estonia – most advanced digital society
UNGGIM
Oman National Spatial Strategy
The Humanitarian Data Exchange – humanitarian sector generally for good examples of cross project collaboration
British Columbia
Take advice from the OGC

Thank you for your time in completing your response to our call for evidence.

Any questions, please get in touch with the Geospatial Commission via geospatialcommission@cabinetoffice.gov.uk

Geospatial Commission: Call For Evidence Response Questionnaire

Please submit your completed questionnaire to:

geospatialcommission@cabinetoffice.gov.uk.

Clearly title your email *'Call for evidence response'*.

About you and your organisation

Name	[Text redacted]
Organisation	Transport Scotland
Job title	[Text redacted]
Address	[Text redacted]
E-mail	[Text redacted]
Telephone	[Text redacted]

Please select which of the following best describes you as a respondent:

Respondent	**Please mark with a X**
Academic	
Business representative / trade body	
Central government	**X**
Charity or social enterprise	
Individual	
Legal representative	
Local government	
Large business (over 250 staff)	
Medium business (50 to 250)	
Small business (10 to 49)	
Micro business (up to 9)	

Other - please state	

Call for evidence - three key themes

We have identified three high-level themes that could help our approach to setting a strategy which are as follows:

1. **Supporting innovation in the geospatial sector**, exploring how to secure cutting edge skills, the right access to data, and opportunities from emerging technologies for the geospatial sector itself
2. **Enhancing the UK's geospatial assets,** looking at how best to align interests, avoid duplication, and instill best practice across the whole public sector
3. **Driving investment and productivity in geospatial applications**, asking in which wider sectors the most value lies from better exploitation and use of geospatial data, in the UK and internationally

Our questions

Q1. Is our view of the geospatial data types accurate? If not, what should be included or excluded from this?

The four types that have been identified are correct; although I would argue that your type "Geospatial Data" and "Positional Data" are an artificial partitioning of Data that has an element within it that identifies where the data is located in 2, 3 and even possibly 4D.

Q2. In addition to current government policy, what are the areas of geospatial skills where the commission could best focus, to help ensure the necessary capability within the UK for the future?

In further education, the understanding of the ability to join data sets together is taught well, but the emphasis of these joins is where the data has an attribute (column) in common. For those education courses where these digital skills are taught, the concept of using a common attribute which is not as column within either of the tables (the location of the observation) can be used to join the two datasets. This limit is artificial due to the way that the courses are designed and taught. Some of the obstacles to this are being eroded with the spatial versions of Commercial databases.

Q3. What are the geospatial skills needs and gaps in your organisations, how can these be most effectively addressed, and how can careers in the sector be best promoted?

In my organisation, the biggest single point of failure is resourcing the Data Management area of the business, specifically the understanding of the creation of Metadata.

This is an area that people are generally bad at, look at the "metadata" associated with this document. In this area of big data etc, being able to find the data will become more and more critical. Metadata creation for spatial will only become mainstream when the creation of Metadata for non spatial documents becomes second nature.

Q4. Are there any publicly or privately-held geospatial datasets that are currently challenging to access or use or of insufficient quality, but which you or your organisation would find valuable if these issues could be resolved? Please explain why this would be of value, and how access/quality could be improved?

Ordnance Survey have a dataset called "Points of Interest" which is specifically excluded as part of the "One Scotland Mapping Requirement". To obtain this dataset, Transport Scotland need to go through a formal procurement process to find the Most Economically Advantageous Tender (MEAT), although this can be for a multi-year contract, the costs of this can require the formal (time consuming) processes to be adopted. The dataset is currently used sparingly (as and when required by large projects) rather than as a core dataset to allow us to build different reports from it. In addition there are licence considerations about the data and potential derived data issues.

Another dataset that would be useful to have would be a complete underground apparatus inventory. This would be helpful during the process of designing new infrastructure and would enable the designers to obtain the definitive information

from one source. At present there are multiple different sources for individual elements of the apparatus, for example telephone lines, water pipes etc.

Q5: Do you anticipate that any changes will be needed to the both address data and the wider address ecosystem, to support emerging technologies? Please provide evidence of value to support any proposed changes.

In summary, the current set of addressing data can be summarised as:

- Local Authority Corporate Address Gazetteers (in Scotland built to the Scottish Conventions (based on BS 7666) and England and Wales based on GeoPlace Conventions
- Royal mail have their own separate addresses
- Valuation offices have some additional data

From these data sources, the AddressBase product set of Ordnance Survey is built.

It is important, in our view that, the base information source for the Addressing products continues to be the Local Authorities as this is closest to the actual address, in addition they need to collect the information already for many other purposes not least Local Taxation.

Considered in the widest sense, the infrastructure that is used for Addressing is currently based on local copies of the Ordnance Survey dataset, which does add value to the Corporate Address Gazetteers. Technology is changing where non-GIS applications need to use AddressBase and provision of a mechanism to access the information as a service from the Web (API access). The details of the use cases that could be covered will need to be further investigated.

Q6: How should the commission be looking to develop the UK's capability in Earth observation data, both technologically and to support an effective market?

The main effort to support the Earth Observation (satellite) capacity building should be in the area of "Analysis Ready Data", where the multiple passes of the satellites are merged into one or more datasets under an Open Government Licence to allow the use and re-use of the data in innovative ways.

Q7. Which new technologies should the commission focus on to provide new opportunities to process and exploit geospatial data for economic growth?

The Open Geospatial Consortium is working on a number of new or updated Geospatial standards. A number of these standards will make it easier to access and use the information that users may wish to consume. The standards are based around a number of newish technologies. The technologies have been in place for a while, but they are now being incorporated into the geospatial standards.

- Modern Open Application Programming Interfaces
- Use of Restful services rather than SOAP or related services
- JSON and GeoJSON

Q8. How can geospatial data and applications be used to support enhanced roll-out of future technologies?

As the various modelling technologies that are being developed start to create more and more detailed models of the real world, geospatial data will become more and more critical to the success of the applications. Extract Transform and Load tools that support spatial and help movement of data between specific formats will become an important too in the armoury of the data architect and the Data Management realm.

Q9: What are the options for how public sector organisations could continue to invest in maintaining and enhancing our geospatial data assets?

Investment in the maintenance and further creation of geospatial data and services is a critical task of the public sector going forward. In the generality, the public sector should be creating data and providing services on the data. The private sector should be creating applications based on the services etc. The funding of the public sector data creation and maintenance where the large organisations need to be self-funding does create artificial limitations to the licencing of data both within the public sector and outside it.

In Denmark, the production of the equivalent of the OS MasterMap Topo dataset is funded by Central Government (Department of Finance) and the use of this

data set is mandated by statute. There is evidence from Denmark of the Private sector producing additional information on top of the Centrally funded data and taxation income to the exchequer coming about.

Q10: What areas of the underpinning geospatial infrastructure such as positioning technologies, including GPS and indoor positioning systems, and geodetic networks and frameworks to support them, should we be prioritising the development of, in order to support the emerging requirements for geospatial data?

The UK Government have made substantial contribution to both the Space programmes of the European Union and losing access to the premium services for Galileo would be unfortunate.

In addition the UK need to up their game on the use of Registers and Registries, it is not clear at this point how new code and codelists are added to existing Registers that are identified in the various geospatial standards that are used. (Gemini 2.3)

Q11: What role should the private sector have in both the development and maintenance of the underpinning infrastructure and enhancing the UK's geospatial data assets?

The role of the private sector should be a supporting and complementary role to the role of the Public Sector. The private sector may be involved in the creation of the Public Sector data (where the Public Sector do not have the facilities to collect it (by tendering for the work)) but the data created would be in the ownership of the Public Sector.

Q12. Do you face challenges when working with geospatial data from across the public sector? If so, what are they and how could value be better released? Are there any technical remedies or standards that could be adopted to improve the interoperability of geospatial data? Please provide supporting evidence of what these remedies could help to accomplish.

The main areas of difficulties are as follows:

- Multiple different licencing regimes (OGL, OSMA/PSMA, CEH licencing, ….) – where a smaller set of more focused licencing conditions were available, re-use of data to create information will be eased.
- Finding the data that is needed. Although the UK has a Metadata catalog (Data.gov.uk), it is extremely difficult to use for finding spatial data. I would argue it is not easy to find non-spatial data either. Transforming the repository from its existing technologies into a more standards based repository (DCAT) will make finding the data easier (and will potentially allow finding of the data direct from well know search engines)

Q13. How can the Geospatial Commission act as a more effective customer for geospatial data on behalf of the public sector?

The main thing that the commission can do is to listen to the Public Sector community. However it is equally important that the commission remember that the GI policy and data as a whole are devolved issues and the commission should work closely with the appropriate leads in the devolved administration to ensure that an England centric view does not emerge, given the relative sizes of England against the other devolved administrations.

Q14. Are there any additional geospatial datasets, from the other partner bodies or other sources, that the public sector would derive significant benefit from having access to, that might have novel and valuable use cases? What would that access look like?

As identified in Q4 – access to underground apparatus may well be a useful data set.

In addition aces to the premium services of both Copernicus and Galileo would potentially be beneficial.

Q15: How can we best develop a single UK strategy, ensuring alignment between the individual strategies across the UK while still allowing for regional variations?

Rather than building a UK strategy to fulfil this purpose, building a UK Strategy Framework in which the 4 devolved ad Gibraltar can insert their more detailed (and relevant to their geographic area) strategies to produce the strategic direction for the UK. In generating the overarching framework the commission needs to work extremely closely with the devolved administrations (as well as Gibraltar) to ensure the framework will fit their needs as well as the Strategic needs of the UK.

Q16: How can we best ensure effective local authority coordination and sharing of best practise, using location data to better deliver public services?

Continuing the current practice of sharing information widely using a specific communication channel seems to be the best idea. Where Local Authorities join together into bodies, like the Improvement Service in Scotland, having frequent briefing and communication with those bodies is key to getting the messages out to the wider community.

Q17: As a result of this analysis, we are prioritising the exploration of possible initiatives in the high-value categories identified:

- **property and land**
- **infrastructure and construction**
- **mobility**
- **natural resources**
- **sales and marketing**

What are the existing or potential geospatial applications which could be scaled-up or developed in order to capture economic value? (We would particularly welcome responses from industry and other bodies engaged in these sectors.)

infrastructure and construction

It is impossible to discuss this area without consideration of BIM and the development from the 2D, to 3D of this environment. Further development of this area to 4D (time) and beyond is happening. Currently the various software suppliers have developed their own software to provide BIM models. Work is

ongoing with the OGC to build a common standard for the exchange of this type of information. The commission's support of bringing the BIM environment into a Geospatial standard will reduce the costs of transfer from one software supper to another. The determining factor will be what software is best for your application rather than which BIM model is best, as all BIM models will be based on the same standard.

Q18: Are there any other areas that we should look at as a priority?

Working with standards organisation to adopt new standards and to strongly encourage the adoption of the standards across the UK public sector which should drive the private sector in the same direction.

Although not specifically spatial, the better adoption of metadata generally is important. In the spatial domain, Gemini is a standard that is adopted in the UK, however the absence of a non-spatial metadata standard is holding back the public understanding of how to find data. In terms of a standard, we would suggest using the DCAT standard.

Q19: What are the main potential private and public sector innovations that will rely on the use of geospatial data to rollout, and are there corresponding regulatory challenges?

Q20: How best can we make the UK's presence in the international geospatial world more visible?

At present the UK is represented by a small group of organisations at the strategic and standard setting levels. These are primarily from the Geo6. As an example at the most recent Inspire Conference, there were only 7 representatives from the UK, two of which attended as they have contracts with the EU to attend the conference. The UK needs to take a more active role in these bodies and we need to have a more diverse set of organisations representing the UK. This will help upskill the profession as well.

Q21: Where should the UK be looking for points of comparison overseas? Who are the other international exemplars? What best practice is being modelled overseas that we can learn from?

As identified earlier in this submission, Denmark has made significant investment in the geospatial industry and it is believed that the financial benefits of this are starting to be seen.

Germany operates in similar space to the UK, where the Central Government do not have direct control over the generation of data and the “regions” have significant responsibility in the domain. The coordination the regions to create a pan-Germany picture seems, at least from the outside, to be effective.

Thank you for your time in completing your response to our call for evidence.

Any questions, please get in touch with the Geospatial Commission via geospatialcommission@cabinetoffice.gov.uk

Geospatial Commission: Call For Evidence Response Questionnaire

Please submit your completed questionnaire to:

geospatialcommission@cabinetoffice.gov.uk.

Clearly title your email *'Call for evidence response'*.

About you and your organisation

Medium business (50 to 250)	
Small business (10 to 49)	
Micro business (up to 9)	

Other - please state	

Call for evidence - three key themes

We have identified three high-level themes that could help our approach to setting a strategy which are as follows:

1. **Supporting innovation in the geospatial sector**, exploring how to secure cutting edge skills, the right access to data, and opportunities from emerging technologies for the geospatial sector itself
2. **Enhancing the UK's geospatial assets,** looking at how best to align interests, avoid duplication, and instill best practice across the whole public sector
3. **Driving investment and productivity in geospatial applications**, asking in which wider sectors the most value lies from better exploitation and use of geospatial data, in the UK and internationally

Our questions

Q1. Is our view of the geospatial data types accurate? If not, what should be included or excluded from this?

The definition of data types seems accurate, however TSP Projects appreciates there is a very thin line between the first two. Further industry specific examples would make its understanding easier. Consider removing the words "Groups of individual" and "grounded in a particular place" from positional data definition to make the sentence clearer.

Q2. In addition to current government policy, what are the areas of geospatial skills where the commission could best focus, to help ensure the necessary capability within the UK for the future?

TSP Projects identified a lack of skills in the following areas: Geospatial Data Management, Basic Cartography, Critical spatial thinking, Data exchange formats and processes.
Universities and Colleges should be funded to provide a stronger geospatial background and software agnostic fundamentals of the processes. Content not covered by academia should be picked up and developed by professional institutions.
Private sector businesses could benefit from tax breaks to provide geospatial training to staff.

Q3. What are the geospatial skills needs and gaps in your organisations, how can these be most effectively addressed, and how can careers in the sector be best promoted?

Some of the skill gaps identified by TSP Projects are: GIS for engineering, Geomodelling, Geostatistics, Interpretation, Digitalisation and use of new geospatial technologies.
The most effective way to address them would be training (starting with Senior Management) and better communications between teams.

Q4. Are there any publicly or privately-held geospatial datasets that are currently challenging to access or use or of insufficient quality, but which you or your organisation would find valuable if these issues could be resolved? Please explain why this would be of value, and how access/quality could be improved?

TSP Projects has found the following list of difficult to access datasets:

- Biological datasets are not fully available (regional areas)
- BGS maps are not available (1:1000)
- Buried services are only available in PDF formats
- Access to Geo-RINM (Network Rail) database not available.

As a solution, there should be a single GOV site to access all information, making it easier to find. The price to access the information should be standardised across the different datasets.

Q5: Do you anticipate that any changes will be needed to the both address data and the wider address ecosystem, to support emerging technologies? Please provide evidence of value to support any proposed changes.

Address data from different GOV bodies seem to be inconsistent. Adopting a standardised country wide (and across all industries) address system would enhance exploitation of geospatial information, facilitating exchange and interoperability.

Q6: How should the commission be looking to develop the UK's capability in Earth observation data, both technologically and to support an effective market?

Many businesses do not have the confidence, skills or budget to try out new EO techniques. In the short term, it is more efficient and less risky for projects to send surveyors out. To support an effective market, the government could provide grant money or benefits to businesses willing to try out innovative EO techniques, or deploy EO techniques and share the data for free in tested areas such as city centres where many different organisations and individuals will feel the benefit. This would help to promote change and make some small companies thrive.

Q7. Which new technologies should the commission focus on to provide new opportunities to process and exploit geospatial data for economic growth?

TSP Projects believes it is key to develop interoperability between current technologies to allow efficient collaboration.

As for new technologies:

- Multispectral high resolution mapping satellites for ground measurements.
- GIS as a tool to analyse information and obtain specific answers - combination with Big Data technologies for real time assessments supported by high speed internet.

Q8. How can geospatial data and applications be used to support enhanced roll-out of future technologies?

Standardisation of file formats and workflows would allow better interoperability paving the way for future technologies. Empower open source developers to make technology accessible. Developing a solid base 3D dataset to support new geospatial technologies.

Q9: What are the options for how public sector organisations could continue to invest in maintaining and enhancing our geospatial data assets?

Publicly funded companies should standardise their geospatial datasets and make them accessible to everyone. They should undertake a combined approach to information management to make the right information available at the right time.
Public funding for investment and enhancement could be provided through a freemium business model where casual or individual users have access for free but regular users pay.

Q10: What areas of the underpinning geospatial infrastructure such as positioning technologies, including GPS and indoor positioning systems, and geodetic networks and frameworks to support them, should we be prioritising the development of, in order to support the emerging requirements for geospatial data?

Local grid with complicated transformations often reflect in time consuming side tasks. GOV could make tools available to overcome this exercise and make it more efficient (cloud based grid transformation services). Alternatively review and assess whether the local grids are needed or could be absorbed by other networks.

Q11: What role should the private sector have in both the development and maintenance of the underpinning infrastructure and enhancing the UK's geospatial data assets?

The private sector should have an indirect role in populating the UK geospatial data. All geospatial information produced as a deliverable to a public organisation should be integrated into the UK system.
A GIS may be a requirement to obtain a building licence, however due to data protection the system should remain confidential and for the sole use of the local authority. Should an external party require it, then consent should be provided by the public organisation.

Q12. Do you face challenges when working with geospatial data from across the public sector? If so, what are they and how could value be better released? Are there any technical remedies or standards that could be adopted to improve the interoperability of geospatial data? Please provide supporting evidence of what these remedies could help to accomplish.

TSP Projects has identified the following challenges:

- Data available in different CAD/GIS/BIM standards, making it hard to merge without spending a long time harmonising.
- Data available in different geospatial formats requiring works to transform from one to another.
- Some environmental data is not in the British National Grid coordinate system requiring lengthy work arounds.

Q13. How can the Geospatial Commission act as a more effective customer for geospatial data on behalf of the public sector?

TSP Projects believes this could be achieved with better use of survey data, often paid for by the public sector then isolated on a project basis. Legacy survey data should be made available from one project to another. Considerations shall be made about risks, liabilities, etc.

Q14. Are there any additional geospatial datasets, from the other partner bodies or other sources, that the public sector would derive significant benefit from having access to, that might have novel and valuable use cases? What would that access look like?

TSP Projects has identified the following datasets:

- OS data
- Public Rights of Way across England
- Conservation area data in shapefile format,
- Tree preservation order across all councils in England
- Flood risk data in Scotland
- 3D Buried services mapping
- Borehole Data, Building Information
- Acess to Geo-RINM (Network Rails GIS)

Q15: How can we best develop a single UK strategy, ensuring alignment between the individual strategies across the UK while still allowing for regional variations?

TSP advises to not be prescriptive, allow room for innovation but demand that information should be shared into nationally held databases and submitted by contractors working in the public interest.
Perhaps even a pay for access model for non public projects.
This should be a private/public joint venture with a data company

Q16: How can we best ensure effective local authority coordination and sharing of best practise, using location data to better deliver public services?

Standardise geospatial systems across local authorities and within them. TSP Projects Environment team experience a large regional variance in terms of local authority environmental and planning data.
Establish forums for sharing good examples of geospatial data use.

Q17: As a result of this analysis, we are prioritising the exploration of possible initiatives in the high-value categories identified:

- **property and land**
- **infrastructure and construction**
- **mobility**
- **natural resources**
- **sales and marketing**

What are the existing or potential geospatial applications which could be scaled-up or developed in order to capture economic value? (We would

particularly welcome responses from industry and other bodies engaged in these sectors.)

A good example developed by Jacobs is ProjectMapper, explanatory video in the following link https://vimeo.com/223200166 . Support the BGS in creating a national geotechnical database and make it mandatory for construction projects to submit data. Currently we have a lot of public sector GIS and GI information out there but it should be collated into one place/resource Data.Gov.Uk was a good starting point.

Q18: Are there any other areas that we should look at as a priority?

TSP Projects would advise to use GIS and Big Data to plan real time events defence (position of security teams, barriers, etc) and public health (epidemics, access to hospitals, etc).

Q19: What are the main potential private and public sector innovations that will rely on the use of geospatial data to rollout, and are there corresponding regulatory challenges?

TSP Projects can foresee the following:

- Autonomous drones for delivery/assessments and Autonomous vehicles for transport of goods and people. There are strong regulatory challenges ahead for both
- Geotechnical and Geological 3D modelling within BIM construction practices (GeoBIM) and its impact in construction
- BIM Level 3 and its impact in the built environment

Q20: How best can we make the UK's presence in the international geospatial world more visible?

TSP Projects would advise to host international conferences at UK major cities and to promote our engineering and geospatial capabilities in events abroad such as the prestigious INTERGEO in Germany.

Q21: Where should the UK be looking for points of comparison overseas? Who are the other international exemplars? What best practice is being modelled overseas that we can learn from?

TSP Projects has identified:

- Japan for 3D geospatial visualisation
- Netherlands for 3D geological risk mapping
- Australia for underground services
- Dubai for technology innovation
- USA for geospatial control networks
- Spain for drones applied to engineering

Thank you for your time in completing your response to our call for evidence.

Call for evidence - three key themes

We have identified three high-level themes that could help our approach to setting a strategy which are as follows:

1. **Supporting innovation in the geospatial sector**, exploring how to secure cutting edge skills, the right access to data, and opportunities from emerging technologies for the geospatial sector itself
2. **Enhancing the UK's geospatial assets,** looking at how best to align interests, avoid duplication, and instill best practice across the whole public sector
3. **Driving investment and productivity in geospatial applications**, asking in which wider sectors the most value lies from better exploitation and use of geospatial data, in the UK and internationally

Our questions

Q1. Is our view of the geospatial data types accurate? If not, what should be included or excluded from this?

yes

Q2. In addition to current government policy, what are the areas of geospatial skills where the commission could best focus, to help ensure the necessary capability within the UK for the future?

Education needs to give more of an emphasis on geospatial data

Do we need improved satellite GPS coverage

Q3. What are the geospatial skills needs and gaps in your organisations, how can these be most effectively addressed, and how can careers in the sector be best promoted?

Training on GIS systems within schools, colleges and universities,. Promote these opportunities via job centre, access to free courses for organisations/schools. CPD recognised courses

Q4. Are there any publicly or privately-held geospatial datasets that are currently challenging to access or use or of insufficient quality, but which you or your organisation would find valuable if these issues could be resolved? Please explain why this would be of value, and how access/quality could be improved?

British Oxygen Cylinders BOC provide us with information on oxygen sent to people's houses but they do not use a UPRN or have up to date information.
Housing associations/hospitals providing information on times they have called an emergency service.
Shared resource for location of emergency vehicles
A national data set for roadworks

Q5: Do you anticipate that any changes will be needed to the both address data and the wider address ecosystem, to support emerging technologies? Please provide evidence of value to support any proposed changes.

Quicker way for local authority custodians to update address base information especially business names

Q6: How should the commission be looking to develop the UK's capability in Earth observation data, both technologically and to support an effective market?

Flooding seems to be a bigger issue within the fire service and it would be useful to have better information on flooding and surface water flooding

Q7. Which new technologies should the commission focus on to provide new opportunities to process and exploit geospatial data for economic growth?

Q8. How can geospatial data and applications be used to support enhanced roll-out of future technologies?

Q9: What are the options for how public sector organisations could continue to invest in maintaining and enhancing our geospatial data assets?

The role of custodian in local authorities seems to be getting less important and a lot of the custodians we speak to have this as part time roles. It would be good to have more clear guidance to how to correctly apply UPRNs as we have flats which have no Parent UPRN. We also have issues with unit location in large shopping centres e.g the intu premise in tyne and wear. Custodians seem to be more focused on revenue collection e.g. council tax than having correctly documented address information

Q10: What areas of the underpinning geospatial infrastructure such as positioning technologies, including GPS and indoor positioning systems, and geodetic networks and frameworks to support them, should we be prioritising the development of, in order to support the emerging requirements for geospatial data?

Q11: What role should the private sector have in both the development and maintenance of the underpinning infrastructure and enhancing the UK's geospatial data assets?

Sharing their data more openly.

Q12. Do you face challenges when working with geospatial data from across the public sector? If so, what are they and how could value be better released? Are there any technical remedies or standards that could be adopted to improve the interoperability of geospatial data? Please provide supporting evidence of what these remedies could help to accomplish.

Encourage the use of UPRNs

Make a part of Addressbase freely available

Q13. How can the Geospatial Commission act as a more effective customer for geospatial data on behalf of the public sector?

Free training courses, increase awareness with governing bodies e.g. CFOA/NFCC

Q14. Are there any additional geospatial datasets, from the other partner bodies or other sources, that the public sector would derive significant benefit from having access to, that might have novel and valuable use cases? What would that access look like?

Q15: How can we best develop a single UK strategy, ensuring alignment between the individual strategies across the UK while still allowing for regional variations?

Q16: How can we best ensure effective local authority coordination and sharing of best practise, using location data to better deliver public services?

Encourage local networking events

Q17: As a result of this analysis, we are prioritising the exploration of possible initiatives in the high-value categories identified:

- **property and land**
- **infrastructure and construction**
- **mobility**
- **natural resources**
- **sales and marketing**

What are the existing or potential geospatial applications which could be scaled-up or developed in order to capture economic value? (We would

particularly welcome responses from industry and other bodies engaged in these sectors.)

Q18: Are there any other areas that we should look at as a priority?

Q19: What are the main potential private and public sector innovations that will rely on the use of geospatial data to rollout, and are there corresponding regulatory challenges?

Q20: How best can we make the UK's presence in the international geospatial world more visible?

Q21: Where should the UK be looking for points of comparison overseas? Who are the other international exemplars? What best practice is being modelled overseas that we can learn from?

Thank you for your time in completing your response to our call for evidence.

Any questions, please get in touch with the Geospatial Commission via geospatialcommission@cabinetoffice.gov.uk

Geospatial Commission: Call For Evidence Response Questionnaire

Call for evidence - three key themes

We have identified three high-level themes that could help our approach to setting a strategy which are as follows:

1. **Supporting innovation in the geospatial sector**, exploring how to secure cutting edge skills, the right access to data, and opportunities from emerging technologies for the geospatial sector itself
2. **Enhancing the UK's geospatial assets,** looking at how best to align interests, avoid duplication, and instill best practice across the whole public sector
3. **Driving investment and productivity in geospatial applications**, asking in which wider sectors the most value lies from better exploitation and use of geospatial data, in the UK and internationally

Our questions

Q1. Is our view of the geospatial data types accurate? If not, what should be included or excluded from this?

Yes

Q2. In addition to current government policy, what are the areas of geospatial skills where the commission could best focus, to help ensure the necessary capability within the UK for the future?

- Improve capability to blend digital geospatial data from different platforms/data sources
- Standardise geospatial marking (e.g. AGS development)

Q3. What are the geospatial skills needs and gaps in your organisations, how can these be most effectively addressed, and how can careers in the sector be best promoted?

Gaps:

- Developed skills in blending 3D data from various sources.
- Constraints in AutoCAD capability, ease of use, speed of use.
- Computer processing and viewing power – and handling of large volumes of 3D data.

Opportunities to address gaps and promote careers:

- BIM promoted to include below ground factual and design data.
- Property sales portfolios to include 3D ground model links including all subsurface assets.
- Improved business links between Ground Investigation Companies and BIM consultants.
- Improved cross discipline communications. (investigator/designer/builder).

Q4. Are there any publicly or privately-held geospatial datasets that are currently challenging to access or use or of insufficient quality, but which you or your organisation would find valuable if these issues could be resolved? Please explain why this would be of value, and how access/quality could be improved?

Desirable improved datasets:

- Underground services – accurate and standardised location data (for historic and newly installed assets) would save time, improve certainty and reduce repetitive expensive investigative work to locate (often repeated by different parties over time). Reduction in strike implications could also be a major H&S benefit.
- Borehole data – open and simplified referencing and feature ID access. Easier access to the wealth of existing and available data held by the BGS on local geology via simplified and standardised referencing and modeling tools would improve conceptual understanding of sites, confidence in site specific studies, a further

means for quality checking, and greater confidence for regulators and stakeholders. It could also potentially minimise site investigation work/ expense/time and avoid layers of repeat investigation over time – providing there was a standard means by which information is fed back in.

Options to improve:

- Options to feedback discovery data into a central database.
- Improved personal geo-locating tools.
- Improved open access tools.
- Development of apps to facilitate above/view what may be available for a site with ease.

Q5: Do you anticipate that any changes will be needed to the both address data and the wider address ecosystem, to support emerging technologies? Please provide evidence of value to support any proposed changes.

Yes!

- Standardise as much as possible, seeking opportunities to adopt a single geo-referencing code/format (AGS?).
- AGS is good for our industry, but could this be enhanced to include land area mapping/boundary definition standardised coding/digitising….

Q6: How should the commission be looking to develop the UK's capability in Earth observation data, both technologically and to support an effective market?

- Enable easier access to accurate location data from cheaper handheld devices.
- Develop technology for more affordable geo-referencing equipment to support georeferencing in aerial drone surveys – without the need for another trade attending site to orient the survey.

Q7. Which new technologies should the commission focus on to provide new opportunities to process and exploit geospatial data for economic growth?

- Drones
- 3D digital (large data) ground modelling processing hardware and software
- BIM software
- Big data processing hardware

Q8. How can geospatial data and applications be used to support enhanced roll-out of future technologies?

Drones – improved ease of use and accuracy of data captured – leading to speedy, intelligent capture of data for a vast platform of business applications.

Underground services – use of common georeferencing would focus developments in how this information is best maximised… currently, non-standard recording of information makes future application design intangible.

Q9: What are the options for how public sector organisations could continue to invest in maintaining and enhancing our geospatial data assets?

Accessibility to point, line, 3D and spatial terrain historic and UK wide data in a common form which works commercially and in the context of site design and BIM.

Cleaning up historical data and standardising the recording of future data – all in a common format.

Creating and then managing/hosting the cloud based data storage infrastructure for future digital aspects. This would ensure security, access standardisation and control over the data usage.

Q10: What areas of the underpinning geospatial infrastructure such as positioning technologies, including GPS and indoor positioning systems, and geodetic networks and frameworks to support them, should we be prioritising

the development of, in order to support the emerging requirements for geospatial data?

1) GPS – handheld and personal devices for use by investigation, design and construction teams – including improvements in accuracy.
2) Satellite receiving and data processing technology
3) GPS surveying geo-locating equipment – reduce expense.

Q11: What role should the private sector have in both the development and maintenance of the underpinning infrastructure and enhancing the UK's geospatial data assets?

- Review of strategic options (and what the priorities would mean for business)
- Pilot trials/tests of emerging developments - from a 'user' perspective.
- Grants/subsidies to roll out new data streams – to kickstart the –uptake of new data formats and useability.

Q12. Do you face challenges when working with geospatial data from across the public sector? If so, what are they and how could value be better released? Are there any technical remedies or standards that could be adopted to improve the interoperability of geospatial data? Please provide supporting evidence of what these remedies could help to accomplish.

Access to data – Single government managed data storage area.
Knowing what's available. (Ditto above)
Format of data – great variation. Standardisation required.

Q13. How can the Geospatial Commission act as a more effective customer for geospatial data on behalf of the public sector?

Partner with business (large and small) to trial improvements to geospatial data commonality, accuracy and ease of access improvements.

Q14. Are there any additional geospatial datasets, from the other partner bodies or other sources, that the public sector would derive significant benefit from having access to, that might have novel and valuable use cases? What would that access look like?

Baseline BGS data.
Baseline UK topographic/land survey data.

Q15: How can we best develop a single UK strategy, ensuring alignment between the individual strategies across the UK while still allowing for regional variations?

Keep the questions and aims simple.

Q16: How can we best ensure effective local authority coordination and sharing of best practise, using location data to better deliver public services?

Get business involvement to drive the links.

Q17: As a result of this analysis, we are prioritising the exploration of possible initiatives in the high-value categories identified:

- **property and land**
- **infrastructure and construction**
- **mobility**
- **natural resources**
- **sales and marketing**

What are the existing or potential geospatial applications which could be scaled-up or developed in order to capture economic value? (We would particularly welcome responses from industry and other bodies engaged in these sectors.)

As per answers above.

Q18: Are there any other areas that we should look at as a priority?

Low/zero carbon energy infrastructure

Q19: What are the main potential private and public sector innovations that will rely on the use of geospatial data to rollout, and are there corresponding regulatory challenges?

Aerial surveying. 3D ground modelling.

Q20: How best can we make the UK's presence in the international geospatial world more visible?

Include 3D and below ground asset information in property portfolios as standard.

Q21: Where should the UK be looking for points of comparison overseas? Who are the other international exemplars? What best practice is being modelled overseas that we can learn from?

The Dutch – national sharing of geo-spatial geological information and improving data coding systems… by law – great!

Thank you for your time in completing your response to our call for evidence.

Geospatial Commission: Call For Evidence Response Questionnaire

Please submit your completed questionnaire to:

geospatialcommission@cabinetoffice.gov.uk.

Medium business (50 to 250)	

Small business (10 to 49)	
Micro business (up to 9)	
Other - please state	

Call for evidence - three key themes

We have identified three high-level themes that could help our approach to setting a strategy which are as follows:

1. **Supporting innovation in the geospatial sector**, exploring how to secure cutting edge skills, the right access to data, and opportunities from emerging technologies for the geospatial sector itself
2. **Enhancing the UK's geospatial assets,** looking at how best to align interests, avoid duplication, and instill best practice across the whole public sector
3. **Driving investment and productivity in geospatial applications**, asking in which wider sectors the most value lies from better exploitation and use of geospatial data, in the UK and internationally

Our questions

Q1. Is our view of the geospatial data types accurate? If not, what should be included or excluded from this?

I would perhaps simplify this list – you have direct geospatial data (any data that has an x/y or other coordinate information) and indirect geospatial data (any data that, by linking with other data, can be geo-referenced).

(Both of these can include raw data but also analytical outputs, and the outputs themselves don't have to be geo-referenced – i.e. they are indirectly referenced (i.e. they can just be a number or some text but based on geospatial calculations and / or data)).

(The coordinate systems can be local (e.g. BIM), national (e.g. BNG) or global (GPS))

Q2. In addition to current government policy, what are the areas of geospatial skills where the commission could best focus, to help ensure the necessary capability within the UK for the future?

Three levels –

1. Raise awareness of geospatial as a career in schools- not only in geography but also in computer science and other areas, and also via careers advice mechanisms.
2. The geospatial apprenticeship - to provide technical skills (how to drive the software, how to capture and edit data using the various tools available
3. MSc programmes – exploring what is under the hood and providing critical thinking/analysis skills at a greater depth – so where a geospatial apprentice might be able to make a high quality map from given data, an MSc graduate should be able to assess whether the data is fit for purpose and 'push back' the request or outline the limitations if this is not the case, comment on data quality, be able to integrate and interoperate data and systems and so forth (a similar level of skill should be present in any Chartered Professional)

Q3. What are the geospatial skills needs and gaps in your organisations, how can these be most effectively addressed, and how can careers in the sector be best promoted?

- (No skills gaps as such as we are a research/teaching organisation)

- Great need for greater awareness of all things geospatial across wider academia – could be achieved by participating in careers fairs at various levels but also organising dedicated events for prospective geospatial students and courses for non-geospatial specialists (e.g. engineers, civil engineers, architects, historians, anthropologists etc)

- Also important to promote geospatial as a career route in schools – there is a lack of awareness about this area – i.e. about careers as a 'geospatial engineer' or 'geospatial scientist' or 'geospatial data scientist'

Q4. Are there any publicly or privately-held geospatial datasets that are currently challenging to access or use or of insufficient quality, but which you or your organisation would find valuable if these issues could be resolved? Please explain why this would be of value, and how access/quality could be improved?

- BIM data is very difficult to get hold of (for use in GeoBIM integration) – both due to being held within private industry and also due to quality / interoperability challenges

Q5: Do you anticipate that any changes will be needed to the both address data and the wider address ecosystem, to support emerging technologies? Please provide evidence of value to support any proposed changes.

The current address ecosystem does not take into account future deliveries or the third dimension – e.g. for use by emergency services (which floor is Flat 329 on) and future drone-type delivery services (information from BIM or other 3D models required to denote specific access points for automated delivery).

Q6: How should the commission be looking to develop the UK's capability in Earth observation data, both technologically and to support an effective market?

Some key challenges with this type of data:

1. Extracting information (as objects)
2. Managing change / time series data
3. Lack of algorithms to process the data in 3D – e.g. vertical interpolation

Along with ongoing research to develop the above there is a need for low-cost (or FOSS) software that can be used by non-experts to exploit this type of data, incorporating clear communication of the limitations of any algorithms. (Desktop GIS is too complex for non expert users)

Q7. Which new technologies should the commission focus on to provide new opportunities to process and exploit geospatial data for economic growth?

- 5G – a strong emerging use case for 3D and 4D data, coupled with BIM, in order to model placement of 5G antennae
- Integrated indoor/outdoor routing and navigation (requires low-cost generation of indoor models and also indoor navigation technology) – safety applications e.g. how a 'bank' staff nurse or doctor navigates their way around an unfamiliar hospital to locate patients and equipement
- Digital twin technology – to enable integrated noise, air quality, energy use and other sensor-based analysis
- 3D/4D modelling to generate integrated indoor/outdoor, above and below ground models (at multiple scales and levels of detail)

Q8. How can geospatial data and applications be used to support enhanced roll-out of future technologies?

Q9: What are the options for how public sector organisations could continue to invest in maintaining and enhancing our geospatial data assets?

- Research into the consequences of poor quality / unavailable geospatial data – how much do mistakes or poor decisions cost the UK every year, how many people are injured, lose their lives – and hence by improving the data quality reduce this cost.

Q10: What areas of the underpinning geospatial infrastructure such as positioning technologies, including GPS and indoor positioning systems, and geodetic networks and frameworks to support them, should we be prioritising the development of, in order to support the emerging requirements for geospatial data?

Integrated indoor/outdoor positioning
Low cost measurement devices to create 3D indoor and outdoor data
Research into data provenance, quality and data usability (and consequences of error/mis-use)
Ability to locate sensors and other IoT devices in 3D space

Q11: What role should the private sector have in both the development and maintenance of the underpinning infrastructure and enhancing the UK's geospatial data assets?

Q12. Do you face challenges when working with geospatial data from across the public sector? If so, what are they and how could value be better released?

Are there any technical remedies or standards that could be adopted to improve the interoperability of geospatial data? Please provide supporting evidence of what these remedies could help to accomplish.

Main challenge is the lack of a single source of data for all organisations. A searchable list and map of what is currently available where would be an excellent starting point. Data.gov.uk works in this regard, but has a high barrier to entry as the metadata standards are relatively complex (e.g. INSPIRE) and not all data is available on this portal..

Also inconsistent data across different public sector organisations (e.g. the London Borough of Camden publishes a map of all the street lights, many others do no).

Perhaps have a low barrier to entry – a minimal standard – so you can publish data with title, keywords and source organisation (captured automatically) – and then raise the data up a 'complete information available scale' as more provenance information is added

Q13. How can the Geospatial Commission act as a more effective customer for geospatial data on behalf of the public sector?

It would be good to promote a change to a 'culture of open by default' – i.e. all data should be open unless there are clear reasons why this should not be done.

Q14. Are there any additional geospatial datasets, from the other partner bodies or other sources, that the public sector would derive significant benefit from having access to, that might have novel and valuable use cases? What would that access look like?

- Access to data produced by construction companies (e.g..geo-referenced BIM) would provide downstream benefits in terms of asset management within the public sector and beyond.

Q15: How can we best develop a single UK strategy, ensuring alignment between the individual strategies across the UK while still allwoing for regional variations?

- Simplified licensing model is required
- Federated data search – one portal linking to others
- Minimum standard of information about the data that should be provided – and that can be generated and updated automatically when the data is uploaded / modified

Q16: How can we best ensure effective local authority coordination and sharing of best practise, using location data to better deliver public services?

Professional organisations such as the AGI could be helpful when coordinating this type of activity. Also a touring road show of 'best practice' going into the various local authorities – with the scope of both demonstrating best practice found in other authorities and also identifying best practice as the road show progresses.

Q17: As a result of this analysis, we are prioritising the exploration of possible initiatives in the high-value categories identified:

- **property and land**
- **infrastructure and construction**
- **mobility**
- **natural resources**
- **sales and marketing**

What are the existing or potential geospatial applications which could be scaled-up or developed in order to capture economic value? (We would particularly welcome responses from industry and other bodies engaged in these sectors.)

Property and land: E-planning – moving away from PDF and 2D towards 3D, and hence the potential to automate checks on planning constraints – e.g. does the building exceed maximum height for this area, does the proposed extension exceed 20% in volume of the overall building, what shadow will be cast by this building

Property and land, infrastructure and construction: Asset management – 'where is asset A', 'what health/safety equipment will I need based on its location' (building on the ongoing activities in BIM)

Q18: Are there any other areas that we should look at as a priority?

Positioning and navigation

Q19: What are the main potential private and public sector innovations that will rely on the use of geospatial data to rollout, and are there corresponding regulatory challenges?

BIM
VR and AR
Transportation (CAV, Uber)
5G
Robotics/autonomous robots
Delivery drones

Q20: How best can we make the UK's presence in the international geospatial world more visible?

- Incoming and outgoing exchanges at high level – e.g. geospatial expert participating in high level trade missions
- Presence at various international fairs, conferences and events
- Online presence – geospatial.uk – highlighting the range of activities with case studies and contacts
- Open invitiation to overseas visitors

Q21: Where should the UK be looking for points of comparison overseas? Who are the other international exemplars? What best practice is being modelled overseas that we can learn from?

- The Netherlands has an extensive number of cases that demonstrate the benefit of a 'open by default' policy with geospatial data (e.g. Geonovum)

- In the UK BIM focus is on large projects/infrastructure – in the Netherlands, Norway, Sweden there is focus on BIM for planning/property development.

Thank you for your time in completing your response to our call for evidence.

Any questions, please get in touch with the Geospatial Commission via geospatialcommission@cabinetoffice.gov.uk

	consultancy for BEIS applying geospatial analysis to energy related data

Call for evidence - three key themes

We have identified three high-level themes that could help our approach to setting a strategy which are as follows:

1. **Supporting innovation in the geospatial sector**, exploring how to secure cutting edge skills, the right access to data, and opportunities from emerging technologies for the geospatial sector itself
2. **Enhancing the UK's geospatial assets,** looking at how best to align interests, avoid duplication, and instill best practice across the whole public sector
3. **Driving investment and productivity in geospatial applications**, asking in which wider sectors the most value lies from better exploitation and use of geospatial data, in the UK and internationally

Our questions

Q1. Is our view of the geospatial data types accurate? If not, what should be included or excluded from this?

These 3 themes seem good. From our perspective/experience some of the lowest hanging fruit can be found in 2.

Q2. In addition to current government policy, what are the areas of geospatial skills where the commission could best focus, to help ensure the necessary capability within the UK for the future?

Encouraging/improving spatial literacy within some of the government departments could provide some early improvements. This could happen on many levels but from our experience of contract work for BEIS, handling energy based datasets (ESOS, RHI, Salix) – these are the products of government policy and contain highly useful spatial information (the locations where the applicants have implemented the energy saving scheme) in the form of an address. **Yet** despite BS7666 having been in place for over a decade these datasets rarely conform to the standard and often diverge wildly. Cleaning these addresses to match back to UPRNs enables detailed analysis of the success or failure of the policy by be able to spatially cross-reference the data with other sources – yet this is a hugely time consuming and tricky process. Simply encouraging or even enforcing government departments to adhere to the use of BS7666 / OSAB / assigning a UPRN whenever an address is used would, in our opinion spatially enable massive amounts of data that at present is difficult to analyse. We have been beating the drum about this for many years at DECC and subsequently BEIS.

I attended William Priest's presentation at RICS on Tues 16th Oct and was disappointed to see that the address based data did not feature in his talk, although I appreciate that the talk was to provide a general overview.

We have also previously talked to the Cabinet Office (GDS) in 2016 when they contacted us about the issue of addresses and energy meters (after an OFGEM response we had made). We presented our work to Rob Maslin and Lawrence Hopper (2nd June 2016) having been put in touch with Paul Downey by Jon Franklin (VOA). At the time they were exploring the possibilities of an open Address Register, and we shared our experience of address matching a range of datasets for our geospatial models here at the UCL Energy Institute.

We would be happy to continue this dialogue / bring the Geospatial Commission up to date with our work since 2016 if this could be of use, particularly with reference to helping geospatial contribute to the Clean Growth Strategy.

Q3. What are the geospatial skills needs and gaps in your organisations, how can these be most effectively addressed, and how can careers in the sector be best promoted?

Spatial literacy and encouraging staff who handle data without realising the geospatial potential that it holds could be improved within our organisation. We have recently launched an MSc in **Energy Systems and Data Analytics** which is the first programme of its kind in the UK, combining the study of Energy Systems with Data Science and part of the course is a geospatial analysis component. But there is still more that we could do.

Q4. Are there any publicly or privately-held geospatial datasets that are currently challenging to access or use or of insufficient quality, but which you or your organisation would find valuable if these issues could be resolved? Please explain why this would be of value, and how access/quality could be improved?

We would argue that the VOA Rating dataset, which recently became available online, but according to the terms and conditions can only used to look at Business Rates whilst we would like to use it for energy based analysis of hereditaments. If government wants these types of data to be used for the benefit of the UK economy it has to release the data without these constraints of use. Our discussions with colleagues at BEIS have suggested that despite being a central government department, they might also be facing similar restrictions for future versions of ND-NEED and other data models that use VOA data as an input.

We are big users of several recent releases of useful data: Environment Agency LiDAR data, HMLR Inspire data, HMLR Price Paid data, BEIS releases of public access gas and electricity consumption data (at aggregate level) and MHCLG release of Energy Performance Certificates and Display Energy Certificates. Any improvements to these datasets would be of great benefit to us, as would the release of further data about the building stock.

Q5: Do you anticipate that any changes will be needed to the both address data and the wider address ecosystem, to support emerging technologies? Please provide evidence of value to support any proposed changes.

We are big users of address based data in many shapes and forms, and I refer to my answer to Q2 in part for my response here.

Regarding the datasets we use I would say that by releasing the NLPG/OSAB as an open government license could be a large step in ‘freeing’ up the spatial element of address based data.

But we recognise that this would be far from simple to achieve (as per our previous discussions with [Text redacted] and [Text redacted] in June 2016.

Q6: How should the commission be looking to develop the UK’s capability in Earth observation data, both technologically and to support an effective market?

Aside from LiDAR and some aerial photography usage we are not experts in this field, although we would encourage any developments that could be used in energy analysis and reducing / balancing energy demand / achieveing the ‘Clean Growth Strategy’.

Q7. Which new technologies should the commission focus on to provide new opportunities to process and exploit geospatial data for economic growth?

This is hard to say and is probably best left to the market, but from a ‘geospatial energy data’ perspective, AI and Machine Learning are probably where some big developments are going to come from in attempts to address the Clean Growth Strategy.

Q8. How can geospatial data and applications be used to support enhanced roll-out of future technologies?

Encouraging more OpenData will encourage new/future technologies.

Q9: What are the options for how public sector organisations could continue to invest in maintaining and enhancing our geospatial data assets?

Investment and maintenance itself could be encouraged by allowing some of these different datasets and organisations to bring different datasets together and exploit the synergy. For example HMLR Inspire data and Ordnance Survey Mastermap data and VOA Ratings data (although via OSAB VOA data can to a certain extent be related to Mastermap though there are limitations).

It should be simple to relate the three datasets to one another, yet it is currently a real headache. Relating them would not only provide insights but could also trigger each organisation to check for changes. For example, a change to MasterMap building polygons could trigger the VOA to revisit a premises to see how floorspace might have changed (resulting in new Business rates). The opposite might equally be the case (a significant change to floorspace data behind the rates might trigger Ordnance Survey to check their building outlines).

Q10: What areas of the underpinning geospatial infrastructure such as positioning technologies, including GPS and indoor positioning systems, and geodetic networks and frameworks to support them, should we be prioritising the development of, in order to support the emerging requirements for geospatial data?

GPS is not an area of expertise for us although we are users of this data at times. Regarding indoor positioning, the roll out of BIM would be of interest to us. To that extent, a method for handling complex 3D data for urban areas would be of great interest (for example how should property ownership be represented in 3D when it is inside muliple occupant buildings).

Q11: What role should the private sector have in both the development and maintenance of the underpinning infrastructure and enhancing the UK's geospatial data assets?

No strong opinion although the underpinning infrastructure should not be left to the private sector.

Q12. Do you face challenges when working with geospatial data from across the public sector? If so, what are they and how could value be better released? Are there any technical remedies or standards that could be adopted to improve the interoperability of geospatial data? Please provide supporting evidence of what these remedies could help to accomplish.

I am repeating my response to Q2 and Q5 to some extent – but the key issue we come across is handling address based data from the public sector (environment agency, BEIS, MHCLG, GLA…) which is often poorly formatted and inconsistent. This data is often not thought of as geospatial, yet if it can be matched to a geospatial version of addresses (NLPG/OSAB) it can become far more valuable/useful.

Other geospatial data from the public sector we can handle because we have staff who can handle most data formats within our organisation. Clearly this would not be the case for many other organisations, who would struggle here although things have improved dramatically over the past decade.

Q13. How can the Geospatial Commission act as a more effective customer for geospatial data on behalf of the public sector?

By encouraging / forcing different public sector organisations to produce datasets that can be cross-related. This might be by light touch regulation on all public sector datasets that have some kind of geospatial component. Enforcing the use of British Standards too (e.g. BS7666) across all government departments!

Q14. Are there any additional geospatial datasets, from the other partner bodies or other sources, that the public sector would derive significant benefit from having access to, that might have novel and valuable use cases? What would that access look like?

The Clean Growth Strategy is going to struggle to make big improvements without easier access to energy data and an ability to make sense of this in the spatial context. This is tricky since a great deal of energy related data is sensitive (either to the customer, provider or from an infrastructure basis). Providing access to government and other accredited organisations whilst maintaining the sensitivity of this data is going to be an increasing issue. A good example is the access to Smart Meter data – an issue that is currently being tackled by colleagues here in the Energy Institute (SMRP).

Q15: How can we best develop a single UK strategy, ensuring alignment between the individual strategies across the UK while still allwoing for regional variations?

Q16: How can we best ensure effective local authority coordination and sharing of best practise, using location data to better deliver public services?

By providing good examples *from* central government and enforcing minimum requirements on any outputs that might feed up to central government or other datasets (as is currently done for LLPG → NLPG)

Q17: As a result of this analysis, we are prioritising the exploration of possible initiatives in the high-value categories identified:

- **property and land**
- **infrastructure and construction**
- **mobility**
- **natural resources**
- **sales and marketing**

What are the existing or potential geospatial applications which could be scaled-up or developed in order to capture economic value? (We would particularly welcome responses from industry and other bodies engaged in these sectors.)

With all of these with the exception of maybe sales and marketing, achieving Clean Growth Strategy targets would return economic value. Our approach is to create geospatial models of the energy demand in all these areas. With better data it is possible to build more realistic simulations, and with these it is possible to both simulate policy and test the effectiveness of policy. From our perspective, applications which push the envelope in this area are to be encouraged. 3D geospatial can be of particular importance here in dense urban areas.

Q18: Are there any other areas that we should look at as a priority?

Q19: What are the main potential private and public sector innovations that will rely on the use of geospatial data to rollout, and are there corresponding regulatory challenges?

Driverless vehicles

Q20: How best can we make the UK's presence in the international geospatial world more visible?

By leading the way instead of looking for others to follow!

Q21: Where should the UK be looking for points of comparison overseas? Who are the other international exemplars? What best practice is being modelled overseas that we can learn from?

In terms of 3D models of the building stock Singapore and New York city have traditionally led the way.

Thank you for your time in completing your response to our call for evidence.

Call for evidence - three key themes

We have identified three high-level themes that could help our approach to setting a strategy which are as follows:

1. **Supporting innovation in the geospatial sector**, exploring how to secure cutting edge skills, the right access to data, and opportunities from emerging technologies for the geospatial sector itself
2. **Enhancing the UK's geospatial assets,** looking at how best to align interests, avoid duplication, and instil best practice across the whole public sector
3. **Driving investment and productivity in geospatial applications**, asking in which wider sectors the most value lies from better exploitation and use of geospatial data, in the UK and internationally

Our questions

Q1. Is our view of the geospatial data types accurate? If not, what should be included or excluded from this?

The four data types identified by the Commission appear to adhere to the vector representation of the world, which is important, but sees entities as discrete objects. The four also relate to precise functions the data may be used for. These types do not adequately cover phenomena that are continuous, such as topography, and that are traditionally represented by a raster data model. The current types also do not really represent Earth Observation data, which comes in an image form, and can largely be described as raster. An additional type that describes data which is represented in an image format would therefore provide a more comprehensive coverage of Geospatial data types.

Q2. In addition to current government policy, what are the areas of geospatial skills where the commission could best focus, to help ensure the necessary capability within the UK for the future?

From the perspective of RSPSoc members, the following areas of focus would be appropriate:

1. Education and training in order to ensure an adequate supply of appropriately trained and qualified staff. The number of taught university courses that focus on, or have a significant component of remote sensing content has been in decline for a number of years. Without these educational opportunities at all levels, in particular FHEQ Levels 6 and 7, it is likely that there will be limitations in skilled labour that will impact on growth in Geospatial industries. In the wake of the 1987 *Chorely Report* (*Handling Geographic Information*) there was a boost in the number of HE courses in GIS, and a similar encouragement is needed now.
2. Recognition of expertise in GIS and Remote Sensing is required. The status of schemes such as the RGS Chartered Geographer needs to be enhanced within industry sectors. Such schemes would have the benefit of encouraging re-skilling of employees within organisations through the requirements of CPD.
3. Policies that ensure the continued supply of certain data sets are required. If industry is to develop products around specific data sets or data products there needs to be long term guarantees of the availability of those data sets or products. The mapping of the UK by the Commissions six partners represent a longevity which needs to be replicated in other field. In the EO sector there is potentially a lack of longitudinal planning in terms of the availability of data sets. The current ESA-EC Copernicus mission represents the potential for such a longitudinal supply of compatible data. Policy/decision around the UK's involvement in Copernicus is required quickly following the UK's exist from the EU.

Q3. What are the geospatial skills needs and gaps in your organisations, how can these be most effectively addressed, and how can careers in the sector be best promoted?

As a learned society RSPSoc has an overview of the potential areas that skills are required in with regards to Earth Observation.

Within the exploitation of EO there is clearly a requirement for those who develop and operator the various sensors and those that exploit the products coming from the sensors. Appropriate training and educational opportunities are clearly essential to support these areas. The current apprenticeships in Geospatial (the L6 *Geospatial Mapping and Science* and the L3 *Geospatial Survey Technician*) are very much built around survey and some GIS skills, and ignore Earth Observation. The development of apprenticeships for Earth Observation, and more broadly for remote sensing, would have an impact on generating both a skilled workforce and enhancing the visibility of career paths in Geospatial, and in particular in Earth Observation. Some consultation would be required about what

level the apprenticeships might be at, but an offering or two (if development of EO and its exploitation are split up) at Level 7 (Masters Level) would perhaps be the best place to start.

In terms of promoting careers in the Geospatial this is something that perhaps needs to be done at both School and University levels. The recent changes in the A level Geography curriculum has put a focus on Geospatial like never before, and this needs to be exploited. There are various initiatives going on, with organisations such as the Royal Geographical Society, the Geography Association and commercial partners, but these need to be supported and more linked up. At university/post-graduation level there are initiatives such as the AGI early careers (ECN) network, and the Space Placements in Industry (SPIN) which are promoting careers relative to Geospatial. These schemes could be broadened.

Q4. Are there any publicly or privately-held geospatial datasets that are currently challenging to access or use or of insufficient quality, but which you or your organisation would find valuable if these issues could be resolved? Please explain why this would be of value, and how access/quality could be improved?

As RSPSoc does not directly use data we are not in a position to answer this question fully, however members of the Society have indicated that greater access to up-to-date imagery would be advantageous. Anecdotally members have made use of the EA's LIDAR data sets, and something similar in terms of imagery would be very useful. The issue with data sets is ensuring a consistent coverage both spatially and temporally.

Q5: Do you anticipate that any changes will be needed to the both address data and the wider address ecosystem, to support emerging technologies? Please provide evidence of value to support any proposed changes.

This is really outside the core areas that RSPSoc represents.

Q6: How should the commission be looking to develop the UK's capability in Earth observation data, both technologically and to support an effective market?

Clearly a significant element in developing and enhancing the UK's capacity is continued engagement in Copernicus. Copernicus provides a very appropriate model of a sensor to product infrastructure for EO. An underpinning to continue supporting this initiative would be appropriate. However, the development of some capability to tailor the data products created through Copernicus would possibly lead to greater usage.

A potential issue with most EO products is the frequency at which they are produced. A step change in capacity would be to have more regular updates of products, such as UK Land cover/land use maps. For commercial organisation to base products on EO data sets those data sets need to be up to date.

A consistency in standards and processing of EO data would also be appropriate. Various standards, such as those through INSPIRE or the Open Geospatial Consortium, exist and these should be consistently applied to produce reliable products.

A gap in the Open Data available in the UK relates to airborne imagery. The OS now has its MasterMap Imagery layer and consideration should be given to how this might be exploited more effectively, and made available to certain user groups as open data or at low cost. Again the issue of updating this would need to be addressed.

As noted in previous responses there is also a need to build capacity in terms of suitably qualified individuals to take on the developments in EO. As noted in Question 3, the development of suitable apprenticeships at FHEQ L7 would be one element of this, but more specific allocations of research funding to dedicated doctoral schools through UKRC for FHEQ Level 8 provision is also needed in order to enhance cutting edge developments.

As part of capacity building the development of professional recognition of EO professionals would be essential, as already alluded to in a previous answer relating to careers (Question 3).

Q7. Which new technologies should the commission focus on to provide new opportunities to process and exploit geospatial data for economic growth?

Technologies that provide real time data are potentially significant. From an EO perspective this might be achieved through the fusion of a range of sensors or by exploiting constellations/swarms of small satellites. As a learned society RSPSoc cannot endorse any specific commercial organisation, but an example of the approach given above might be Planet.com, who combine their satellite sensors to provide daily coverage. The other major examples would be something like the Disaster Monitoring Constellation and of course Copernicus.

Q8. How can geospatial data and applications be used to support enhanced roll-out of future technologies?

The development of future technologies will partly be dependent on what geospatial data is available to "fuel" them. However there is also the development of future technologies that can lead to the creation of new geospatial data and applications. As noted above, the development of "cheap" constellations/swarms of small satellites should lead to the creation of more bespoke data. Further developments in the sensor suites carried by UAV, and other types of drones, will also further enhance data collection, which should in term drive new applications.

Q9: What are the options for how public sector organisations could continue to invest in maintaining and enhancing our geospatial data assets?

Potentially the role for the public sector is to maintain the key data sets that can then be exploited by other downstream users. The missing element in the current partners of the Commission, which are responsible for key data sets, is a body/representative to be responsible for EO. Whether a role for other government executive agencies, such as the UK Space Agency and the Met Office, who are large users of EO should be found should be considered.

Q10: What areas of the underpinning geospatial infrastructure such as positioning technologies, including GPS and indoor positioning systems, and geodetic networks and frameworks to support them, should we be prioritising the development of, in order to support the emerging requirements for geospatial data?

From an EO perspective the areas that should be focused on are positioning and calibration. The maintenance of a national network of GNSS receivers is essential for ensuring the accuracy of Geospatial data sets. Access to GNSS satellites is also essential, ideally from more than one constellation (i.e. not just GPS, but also potentially Galileo or other alternatives).

In addition, the development of calibration sites for satellite EO would enhance the UK's ability to produce pre-processed products, and potentially enhance the use of EO. A network of calibration sites, as explored by the NCAVEO (NERC Calibration and Validation of Earth Observation data) project, would greatly enhance the capacity in the UK to produce products that are ready to use. Further background on the development of such a network can be found at the CEOS supported project QA4EO (Quality assurance framework for earth observation).

Q11: What role should the private sector have in both the development and maintenance of the underpinning infrastructure and enhancing the UK's geospatial data assets?

The public sector should be providing a basic infrastructure in relation to positioning and calibration (certainly in terms of EO), but this network could be enhanced by private sector organisations. The potential for public-private initiatives is great in this area. The role for the Commission should be to ensure that any infrastructure is in the national interest, and that both geographical areas and thematic sectors that are not deemed to be commercially attractive are also covered.

Q12. Do you face challenges when working with geospatial data from across the public sector? If so, what are they and how could value be better released? Are there any technical remedies or standards that could be adopted to improve the interoperability of geospatial data? Please provide supporting evidence of what these remedies could help to accomplish.

This is a question that is not really applicable to RSPSoc as we have such a varied membership who will experience a range of issues in relation to accessing Geospatial data and services.

Q13. How can the Geospatial Commission act as a more effective customer for geospatial data on behalf of the public sector?

The Commission's role should be to ensure that core infrastructure and data are available. There is also a role for the Commission to ensure the longevity and sustainability of core products and service. The nature of the private sector suppliers of Geospatial data is such that commercial consideration need to take priority, and ensuring the longevity of a particular data set is not necessarily a priority. The Commission's role should therefore be to identify core requirements and ensure that these can be sustained. In collaboration with agencies and organisations such as the Catapults and Innovate UK addition capacity can be created.

Q14. Are there any additional geospatial datasets, from the other partner bodies or other sources, that the public sector would derive significant benefit from having access to, that might have novel and valuable use cases? What would that access look like?

From the EO perspective having the equivalent of national mapping made up of aerial photography would be a major step forward. There is a potential for such a layer of Geospatial data to be developed by a public-private initiative. Such a layer would have a cost to it, and a model of access which differentiates between total open access for some users and a charge for others would seem to be the most appropriate.

Q15: How can we best develop a single UK strategy, ensuring alignment between the individual strategies across the UK while still allowing for regional variations?

There clearly needs to be an overarching strategy for the UK as a whole as geographical features and phenomena do not stop at the borders between the Devolved Administrations. The Commission should identify a series of core requirements in relation to the exploitation of Geospatial data, high amongst these should be interoperability in terms of both data and services. Core standards, along the lines of something like INSPIRE, should be identified for the collection, storage and exploitation of data. There should be an agreement on the way that core data sets are collected, updated and made available. The strategy should also be seen as a way of sharing good practice, and as the basis of the development of a core set of information for all DAs. The issues we are likely to experience in the future will be as a geographical region irrespective of the political configuration that exists at that time. Recent natural disasters have shown that nature does not respect political boundaries.

Q16: How can we best ensure effective local authority coordination and sharing of best practise, using location data to better deliver public services?

This is not really a question that RSPSoc can comment on.

Q17: As a result of this analysis, we are prioritising the exploration of possible initiatives in the high-value categories identified:

- **property and land**
- **infrastructure and construction**
- **mobility**
- **natural resources**
- **sales and marketing**

What are the existing or potential geospatial applications which could be scaled-up or developed in order to capture economic value? (We would particularly welcome responses from industry and other bodies engaged in these sectors.)

This is not really a question that RSPSoc can comment on.

Q18: Are there any other areas that we should look at as a priority?

While perhaps not of immediate commercial value there is a need to consider how we monitor and manage the built and natural environment. The increasing frequency of extreme weather events has highlighted issues that need to be addressed around how we plan and develop the landscape. So while not necessarily commercial in terms of generating income, the potential to save lives and to save money is clear to see. There are also wider climate change problems that we should be looking to monitor and manage using Geospatial. Again the direct commercial value may not be visible, but the benefits over time will impact on society as a whole.

Q19: What are the main potential private and public sector innovations that will rely on the use of geospatial data to rollout, and are there corresponding regulatory challenges?

Regulatory challenges exist around the balance between the good of society and the need to preserve an individual's privacy. How GDPR will work with Geospatial information is still not clear. There is also likely to be challenges around the use of Geospatial data and ensuring there is equality in access to information.

Q20: How best can we make the UK's presence in the international geospatial world more visible?

From an EO perspective there is already a great deal of respect and recognition for the work going on in the UK. The Commission's role should therefore be to ensure that the UK EO community/industry can continue to collaborate and engage with partners on the world stage. Some of the issues relating to technology transfer that have arisen out of the UK's forthcoming exit from the EU need to be addressed to ensure that the excellence in the UK EO community can continue to collaborate on an equal footing with other countries.

Geospatial Commission: Call For Evidence Response Questionnaire

Please submit your completed questionnaire to:

geospatialcommission@cabinetoffice.gov.uk.

Clearly title your email *'Call for evidence response'*.

About you and your organisation

Name	[Text redacted]
Organisation	UKHO
Job title	[Text redacted]
Address	[Text redacted]
E-mail	[Text redacted]
Telephone	[Text redacted]

Please select which of the following best describes you as a respondent:

Respondent	**Please mark with a X**
Academic	
Business representative / trade body	
Central government	**X**
Charity or social enterprise	
Individual	
Legal representative	
Local government	
Large business (over 250 staff)	
Medium business (50 to 250)	
Small business (10 to 49)	
Micro business (up to 9)	

Other – please state	

Call for evidence – three key themes

We have identified three high-level themes that could help our approach to setting a strategy which are as follows:

1. **Supporting innovation in the geospatial sector**, exploring how to secure cutting edge skills, the right access to data, and opportunities from emerging technologies for the geospatial sector itself
2. **Enhancing the UK's geospatial assets,** looking at how best to align interests, avoid duplication, and instill best practice across the whole public sector
3. **Driving investment and productivity in geospatial applications**, asking in which wider sectors the most value lies from better exploitation and use of geospatial data, in the UK and internationally

Our questions

Q1. Is our view of the geospatial data types accurate? If not, what should be included or excluded from this?

No:
- 1 should say "where place is a key feature of its subject" rather than "its source". The definition as written is somewhat ambiguous.
- 4 should talk about "insights, products and services", not just "insights and products".
- 4 should also be wider, e.g., "… involving the fusion and analysis of layers" not just "involving layers".

Q2. In addition to current government policy, what are the areas of geospatial skills where the commission could best focus, to help ensure the necessary capability within the UK for the future?

- Data Science (AI, ML and data analysis)
- Data Engineering
- Data Management
- Earth Observation
- Geospatial and GIS skills
- DDAT skills, especially Software Engineering

Individuals that combine these skills, e.g. data science with earth observation, or GIS with software engineering, are especially valuable. This multi-faceted aspect should be reflected in educational programmes.

Q3. What are the geospatial skills needs and gaps in your organisations, how can these be most effectively addressed, and how can careers in the sector be best promoted?

- In our organisation we struggle to address skill gaps in data science, data engineering and software engineering, especially where those skills are combined with geospatial experience. This is largely due to a lack of such skills in the wider economy but something that could be addressed through greater collaboration with academia.

- Foresight Future of the Sea outlines that 'Autonomy and robotics' will challenge the UK's skills base and recommended the support of mechanisms to 'join up' diverse sectors of marine including around skills (Page 10 of Foresight: Future of the Seas). It also stated that analytical skills and greater coordination between marine sectors was key to enabling big data and driving innovation (Pg 14). In addition DfT Maritime 2050 strategy is looking at the challenges associated with getting the UK 'Marine Autonomous Navigation ready'.

- The creation of specific geospatial clusters in areas of comparative advantage (in our case a marine orientated one in the SW) would help to solve this problems by creating a self-reinforcing eco-system of Geospatial Partner Bodies, other agencies, local government, industry and regional educational institutions such as schools, colleges and university alongside private businesses. This type of effect and its benefits are seen most clearly in the UK in Cambridge.

- Leveraging on existing regional work, for example 'Digital Skills Devon' is already looking at issues associated with digital careers and the South Coast Marine Cluster (industry, Government, Local Enterprise Partnerships) is already promoting marine especially around autonomy and data. A Marine Geospatial Cluster and innovation centre in the South West would join up and enhance these existing initiatives and hence addressing issues outlined in the Foresight report.

Q4. Are there any publicly or privately-held geospatial datasets that are currently challenging to access or use or of insufficient quality, but which you or your organisation would find valuable if these issues could be resolved? Please explain why this would be of value, and how access/quality could be improved?

- UK (both Gov and Private) marine geospatial data holdings are complex and held by many organisations. Often this data is collected for a single use and not published more widely. Simply requiring government agencies and private sector organisations, e.g. as a condition of planning permissions, to put copies of their data into nominated, marine data asset would ease this problem significantly. As an example, there are over 20 Government agencies, along with port authorities, local authorities and private companies collecting bathymetric (the marine equivalent of topographic) data in the UK and, whilst the UK Hydrographic Office is the authority for such data, it has no power to ensure that data is deposited and made available for other uses.
- Profiling and championing of the UKHO as the custodian of the UK Governments marine geospatial data asset is intrinsically linked to the effectiveness and value of that data asset i.e. it won't deliver on what we want it to if no one knows it is there or how to access it.
- Adopting common standards for naming, georeferencing and other metadata would greatly aid the meaningful collation, analysis and application of aggregated marine data such as bathymetry.
- The lack of a high resolution national bathymetric data set may become a barrier to the development and adoption of autonomous shipping in UK waters, which may in turn restrict the competitiveness of UK ports.
- Potential changes in regulation may be needed to ensure that data captured by private companies under license to HMG is automatically made available for wider use.

Q5: Do you anticipate that any changes will be needed to the both address data and the wider address ecosystem, to support emerging technologies? Please provide evidence of value to support any proposed changes.

- More thought needs to be given to the interface of marine and land data, especially in areas, such as ports, where effective economic activity requires the analysis of data from these two different domains.

Q6: How should the commission be looking to develop the UK's capability in Earth observation data, both technologically and to support an effective market?

- The UK's Earth Observation (EO) data capability could be enhanced by expanding the availability of low cost/free high resolution multispectral EO data. Currently the land centric approach to data collection means that its availability is restricted in coastal and offshore data for example the UKHO had to pay commercial rates for EO data of the UK Overseas Territories as part of the UK OT Seabed Mapping Programme.

Q7. Which new technologies should the commission focus on to provide new opportunities to process and exploit geospatial data for economic growth?

- Improved EO sensor technology.
- Improved surveying technology, including autonomous platforms.
- The use of AI and machine learning to improve and extract insight from EO and survey data.
- The addition of geospatial functionality to key open source big data technologies.
- An area of focus should include the interface between the data owner/aggregator and the user. This often requires data to transfer between technologies and sectors; therefore, agreed API and appropriate metadata standards would be a key enabler.
- The use of distributed ledger technology (DLT), to ensure provenance and traceability, and smart contracts, to ensure frictionless use, could also be key enablers for the effective use of geospatial and other Government data.

Q8. How can geospatial data and applications be used to support enhanced roll-out of future technologies?

- Autonomous shipping will throw up many challenges, this will include areas such as reliance on accurate bathymetric, weather and tidal models, routing information and more explicit depiction of restriction and constraint information (i.e. it will need to be captured and presented in a machine, rather than human, understandable way).

- DLT, machine interpretable or smart licenses will be needed to support an automated ecosystem of geospatial data suppliers, value-added analysts and end users.

- The UK still has a comparative advantage in the marine/maritime space. This status is reflected in the size and scope of 'Maritime London' as a sector, the only UN building in the UK is maritime focused (IMO), and NATO's Maritime Commander is also UK based. The UKHO's data asset is truly global covering a primary charting portfolio of 71 coastal states and it runs data collection programmes in over 30 of those.

- As such the availability and quality of UK marine geospatial data supports the development of UK businesses and technology both in the UK and overseas. For example, Foresight Future of Sea not only suggests that data collection activities need to be expanded globally (recommendation 20) that they should stimulate innovation (recommendation 19) but that autonomy and sea bed mapping are 'Key sectors to create a long-term platform for UK business to capitalise on growing global opportunities (recommendation 1).

- UK Government aspirations (DfT Maritime 2050 / FCO International Oceans Strategy – currently in late draft stage) to support a global mapping programme could be a significant stimulant to the development of surveying and data technology, including autonomous platforms. E.g. international develop policy and activity (and subsequent data collection contracts as seen by UKHOs part in the Commonwealth Marine Economies Programme) could stimulate the development of autonomous data collection methods.

- Foresight strongly outlines as part of its four structural issues (page 9) that of the trends and recommendations (economic, environmental, international engagement and marine science) are 'overwhelmingly global'. As such future considerations for how the Geospatial Commission approaches issues such as Governance and data platforms need to be cognisant of the broader, expansive and global approach that the UKHO's current activities need to have. These activities are predominantly UK and outwardly looking (and this is positive when it comes to UK businesses operating globally) rather than UK landward/inward.

Q9: What are the options for how public sector organisations could continue to invest in maintaining and enhancing our geospatial data assets?

- Even with the increasing availability and utility of EO data and the advent, albeit at an early stage, of low-cost autonomous surveying platforms, the collection of marine geospatial data is extremely expensive.

- A more coordinated approach to the collection and dissemination of marine geospatial data would minimise duplication and maximise the value of every £ invested in collecting marine geospatial data.

- The UKHO believes that being able to generate value from its data is vital to the overall health of surveying activity. Additionally, it would be reasonable for the UK Hydrographic Office to run the UK Civil Hydrographic Programme (currently managed by Maritime Coastguard Agency) in order to better coordinate broader UK marine geospatial data requirements and deliver best value for money and data into the marine geospatial data asset.

- Foresight specifically recommends encouraging 'mechanism to address insufficient join up' (recommendation 4) and coordination between sectors to 'enable big data to be a driver of innovation' (recommendation 19). These fit well with Boston Consulting Groups unlocks (from the Digital Land review) which highlighted the 'Fix not regrets' issue of better coordinating existing activities including sea surveying (Unlock #6).

Q10: What areas of the underpinning geospatial infrastructure such as positioning technologies, including GPS and indoor positioning systems, and geodetic networks and frameworks to support them, should we be prioritising the development of, in order to support the emerging requirements for geospatial data?

- DGPS and its equivalents are essential to the economy as they drive a huge number of location aware services and data collection activities. There is currently a reliance on US, EU and Russia based systems and the UK should consider a UK based alternative.
- The UK should develop and enforce a full spatial data infrastructure (see ODI definition).
- Autonomous data collection systems.

Q11: What role should the private sector have in both the development and maintenance of the underpinning infrastructure and enhancing the UK's geospatial data assets?

- In the case of marine geospatial data; the UK private sector provides the majority of the data collection capability with services contracted in to support annual data collection programmes. Government should retain maintain responsibility where regulation, sovereignty (especially in defence sector and critical national infrastructure) and standards require this.

- The key thing with any private sector involvement is that it is not allowed to evolve into lock-in a proprietary solutions.

- In the context of enhancing, business is likely to be more effective at identifying the need to improve and then driving solutions and it is the role of Government to enable these activities rather than to try and predict.

Q12. Do you face challenges when working with geospatial data from across the public sector? If so, what are they and how could value be better released? Are there any technical remedies or standards that could be adopted to improve the interoperability of geospatial data? Please provide supporting evidence of what these remedies could help to accomplish.

- Foresight specifically recommends encouraging ‘mechanism to address insufficient join up’ (recommendation 4) and coordination between sectors to ‘enable big data to be a driver of innovation’ (recommendation 19). These fit well with Boston Consulting Groups unlocks (from the Digital Land review) which highlighted the ‘Fix not regrets’ issue of better coordinating existing activities including sea surveying (unlock #6).

- UK Governments marine geospatial data holdings are complex and held by multiple arms-length bodies. Often this data is collected for a single use and not published more widely. Simply requiring government agencies and private sector organisations, e.g. as a condition of planning permissions or managing shellfish health, to put copies of their data into nominated, marine data asset would ease this problem significantly. As an example, there are over 20 Government agencies, along with port authorities, local authorities and private companies collecting bathymetric (the marine equivalent of topographic) data in the UK and, whilst the UK Hydrographic Office is the authority for such data, it has no power to ensure that data is deposited and made available for other uses.

- The creation of specific geospatial clusters in areas of comparative advantage (in our case a marine orientated innovation centre in the SW) would help to solve this problem by creating a self-reinforcing eco-system of Partner Bodies, other agencies, local government, industry and regional educational institutions such as schools, colleges and university alongside private businesses. This type of effect and its benefits are seen most clearly in the UK in Cambridge.

- There is a lack of standards, lack of metadata, inability to determine what represents the authoritive master data set, the scattered nature of data and the difficulty in knowing what is actually available.

- There are also problems with restrictive licensing terms and have to pay royaltiies for data that has often been collected under license to HMG.

- The role and requirements of the Devolved Administrations need to be considered separately from ALBs and Central Government Departments.

Q13. How can the Geospatial Commission act as a more effective customer for geospatial data on behalf of the public sector?

- The Geospatial Commission should encourage more efficient planning of cross government marine geospatial data collection, aggregation and dissemination to avoid duplication of effort across the public sector to realise efficiencies and ensure that the UK has a comprehensive view of its marine geospatial holdings which can be used to best effect to support private sector enterprise.

- The GC should consider inclusion of marine products and services within its concept for the future Public Sector Mapping Agreement. For example, Crown Estates are currently purchasing UKHO products from the private sector in contrast to OS products which they get through the current PSMA framework.

- Where the GC gets involved in projects it should encourage the use of open geospatial standards and use of open source tools/code.

Q14. Are there any additional geospatial datasets, from the other partner bodies or other sources, that the public sector would derive significant benefit from having access to, that might have novel and valuable use cases? What would that access look like?

- UK Government has significant agencies that collect and aggregate marine geospatial data for multiple uses. This list has been provided to the Geospatial Commission. Access to that data would be via one UK national marine geospatial data asset. Arms-length bodies should be encouraged to provide their marine geospatial datasets to the UKHO who can manage the authoritative marine geospatial data asset.

Q15: How can we best develop a single UK strategy, ensuring alignment between the individual strategies across the UK while still allowing for regional variations?

- Encourage stakeholder engagement and effective governance. Seek alignment or sort out the hierarchy of policy e.g. will the Geospatial Strategy sit beneath the Government Data Strategy etc; the policy landscape is confusing and needs to be rationalised.

- Regional variation will be subject to the topic covered; for example; discharging the UK's Safety of Life at Sea Convention requirements for the provision of maritime safety information and hydrographic services to support navigation are not devolved and are therefore uniform across the UK. An analysis of the implications of devolution will be required to ensure correct regional variation.

- Acknowledge that marine geospatial data is an enabler for understanding many other marine activities and challenges such as climate change, maritime security, plastics, disaster response, seabed mining, blue economy, tourism, defence, fisheries and aquaculture etc and as such needs to be reflective of their associated national and international strategies and policies (for example FCO International Oceans Strategy, DfT Maritime 2050 and UN Sustainable Development Goals).

Q16: How can we best ensure effective local authority coordination and sharing of best practise, using location data to better deliver public services?

- Engagement with Local Authorities will be required to raise awareness of the opportunities associated with harnessing geospatial data. Raising awareness in this sector will be key.

- Delivery of a marine geospatial cluster and innovation hub will require coordination with local councils and the Heart of the South West Local Enterprise Partnership.

Q17: As a result of this analysis, we are prioritising the exploration of possible initiatives in the high-value categories identified:

- **property and land**
- **infrastructure and construction**
- **mobility**
- **natural resources**
- **sales and marketing**

What are the existing or potential geospatial applications which could be scaled-up or developed in order to capture economic value? (We would particularly welcome responses from industry and other bodies engaged in these sectors.)

- Need to ensure that these are not all viewed from a ‘land’ perspective and that they are interpreted in the widest way e.g. mobility covers autonomous shipping and logistics in general, infrastructure covers offshore assets and natural resources includes fishing, wind farms, oil and gas etc.

- Consider the impact/signalling of not including any aspect of marine at all within GC priorities (disengagement from marine geospatial stakeholders beyond UKHO).

- Marine Geospatial, autonomy and Innovation Centre would support industry ambition outlined within the South Coast Marine Cluster (notably marine autonomy)

Q18: Are there any other areas that we should look at as a priority?

- AI
- Autonomous shipping (and innovation) is a priority for industry and the UK Government (DfT Maritime 2050); this area offers significant opportunity for Government, industry and academia to work together to ensure that the UK capitalises on the opportunities associated with this technological revolution.

Q19: What are the main potential private and public sector innovations that will rely on the use of geospatial data to rollout, and are there corresponding regulatory challenges?

- Regulatory changes will be required by the International Maritime Organisation (IMO) to make autonomous shipping a reality. UKHO is working with DfT to contribute to the ongoing work on autonomous shipping navigation regulations.

Q20: How best can we make the UK's presence in the international geospatial world more visible?

- Work with DIT to identify export opportunities for Government and Private sector services; e.g. the provision of Marine Spatial Data Infrastructure to other governments to help them manage their marine domains.
- Contribute to international geospatial for a e.g. the UNGGIM, raise awareness and note the contribution to international for a by the Government geospatial bodies, e.g. the UKHO's contribution to the International Hydrographic Organisation.
- Be at the forefront of geospatial innovation.
- AI

Q21: Where should the UK be looking for points of comparison overseas? Who are the other international exemplars? What best practice is being modelled overseas that we can learn from?

For an example of best practice consider the US Federal Geographic Data Committee (FGDC) https://fgdc.gov/ where the focus is on collaboration, partnerships, coordination, standards, metadata and interoperability.

Thank you for your time in completing your response to our call for evidence.

Any questions, please get in touch with the Geospatial Commission via geospatialcommission@cabinetoffice.gov.uk

Geospatial Commission: Call For Evidence Response Questionnaire

Please submit your completed questionnaire to:

geospatialcommission@cabinetoffice.gov.uk.

Clearly title your email *'Call for evidence response'*.

About you and your organisation

Name	[Text redacted]
Organisation	UKRI
Job title	[Text redacted]
Address	[Text redacted]
E-mail	[Text redacted]
Telephone	[Text redacted]

Please select which of the following best describes you as a respondent:

Micro business (up to 9)	

Other - please state	

Call for evidence - three key themes

We have identified three high-level themes that could help our approach to setting a strategy which are as follows:

1. **Supporting innovation in the geospatial sector**, exploring how to secure cutting edge skills, the right access to data, and opportunities from emerging technologies for the geospatial sector itself
2. **Enhancing the UK's geospatial assets,** looking at how best to align interests, avoid duplication, and instill best practice across the whole public sector
3. **Driving investment and productivity in geospatial applications**, asking in which wider sectors the most value lies from better exploitation and use of geospatial data, in the UK and internationally

Our questions

Q1. Is our view of the geospatial data types accurate? If not, what should be included or excluded from this?

Agree that these are an accurate view of geospatial data although an additional element may need to be considered for future use.

Geospatial data holds great potential for how we manage the environment and our natural assets (e.g. woodlands, tidal power) as well as our built and agricultural (crops, soil, water use) environment. Therefore an addition to definition of 'Positional data' which embraces that assets could be 'natural' as well as 'physical' is suggested as follows:

"Groups of individual datasets that usually have location as a secondary purpose, and which describes activity, physical **or natural** assets grounded in a particular place."

A relatively new aspect of geospatial data is the temporal element. Often the change in data, because of an update, has an additional value for research or commercial exploitation. In a historical context, this is clear but in modern digital and automated data collection, the temporal change element is the basis of exploitation of the data. This could be considered under the definition of geospatial services or even as a factor in its own right.

Q2. In addition to current government policy, what are the areas of geospatial skills where the commission could best focus, to help ensure the necessary capability within the UK for the future?

There is a need for people with skills in data management, data use, as well as in model development which make use of geospatial data. Specifically this should extend to the use of Artificial intelligence, especially for computer vision and data analysis.

These skills are needed in academia as well as business to help ensure a strong pipeline of geospatial data (through academic research) and to drive business innovation through the exchange of data/knowledge. In agriculture in particular, multidisciplinary teams are needed to interpret data into useful information for farmers (for example, geospatial data could inform a farmer that more nitrogen is needed in part of a field; a robot could then apply more fertiliser).

It is important that these people have enough subject specific expertise to understand how to apply geospatial data to novel applications (i.e. what can the data, or combinations of data reliably tell us).

Further development of skills in modern digital data collection techniques, including satellite-derived earth observation, are required to capture the emerging opportunities relating to the application of these technologies.

There is a wider generic skill set requirement in understanding the power and value of geospatial data. This is an impediment to adoption as potential users do not realise there may be a geospatial solution to a given problem. The Geospatial Commission will be uniquely positioned to deliver a powerful public awareness message to government, business and the public.

Q3. What are the geospatial skills needs and gaps in your organisations, how can these be most effectively addressed, and how can careers in the sector be best promoted?

Skills gaps
The Natural Environment Research Council (NERC), one of the research councils of UKRI, identified skills gaps within the environmental sciences research community (https://nerc.ukri.org/skills/postgrad/policy/skillsreview/2012/), in addition to this NERC has an open 'call' for evidence submissions for training needs (Ref: https://nerc.ukri.org/funding/available/postgrad/focused/cdt/evidence/). Many of these skills gaps are shared across UKRI and are relevant to geo-spatial data.

Skills Gaps:

- Data management

- Interrogating and interpreting large datasets and data mining
- Large scale data manipulation
- Understanding data integrity protocols and assurance
- Understanding and managing uncertainty (in data and products derived from data)
- Numerical and mathematical modelling
- Statistical methods for handling, analysing and interpreting large datasets
- Data licensing
- Data visualisation
- Data models to predict future outcomes or understand what is happening in real time
- Artificial Intelligence

Responses to the ESRC's 2017 Skills Review highlighted similar skills gaps around advanced quantitative methods and data science, which included geospatial data (https://esrc.ukri.org/news-events-and-publications/news/news-items/knowledge-and-skills-needs-call-for-evidence-summary-report-and-next-steps/).

Prior to this the UKRI's Research Careers Network (which includes the Heads of Careers and Training, or equivalents, from across UKRI), identified data driven research and its applications as being a skills gap that cuts across all UKRI communities, this included 'systems approaches, research software engineering, visualisation, statistical approaches, risk and uncertainty, modelling, prediction and machine learning. As well as the need to develop quantitative skills to ensure that 'big data' is fully utilised across disciplines'.

We anticipate that many of these skills gaps are shared by businesses who are using geospatial data to develop new products and services. Addressing these skills gaps is vital to ensure a pipeline of high quality geo-spatial data from the publically-funded research base and its application into business services and products.

How can skills gaps be addressed?

In order to nurture highly skilled people capable of generating innovation and growth, UKRI invests in a variety of training including PhD and postgraduate training, short courses, and placements between academica and non-academic sectors. By working with universities and employers we equip graduates with skills needed to evaluate and use evidence and data across business and government sectors. These existing mechanisms for training can be strategically targeted to address specific skills gaps identified by UKRI, our partners in policy and business and are an established route through which skill development in the geospatial area could be developed.

Specifically NERC has started to address data related skills gaps, in environmental sciences though Centres for Doctoral Training (CDTs) in Data, Risk and Environmental Analytical Methods (DREAM), which is co-funded with

ESRC and Quantitative and Modelling Skills in Ecology and Evolution (QMEE). In addition, in its second round of Doctoral Training Partnerships (DTP2) NERC made the provision of 'Access for all students to appropriate data skills training' a requirement.

ESRC has invested in advanced quantitative methods, including geospatial data collection and analysis, via Q-STEP (http://www.nuffieldfoundation.org/q-step), an interdisciplinary Centre for Doctoral Training (https://datacdt.org/) and through incentivising the development of training in advanced quantitative methods and data skills through our Doctoral Training Partnerships. In addition broader training provision is offered via the National Centre for Research Methods (https://www.ncrm.ac.uk/training/).

Innovate UK has provided a long-standing solution, in partnership with the rest of UKRI, for business-led skill needs in the form of Knowledge Transfer Partnerships (KTP). This programme provides an immediate bridge between the research base and industry to transfer new or innovative skills into industry. This is a flexible tool and applicable to any number of geospatial skill gaps.

The UKRI are also investing in CDTs that focus on areas relevant to Artificial Intelligence. A call for applications closed in July 2018 and announcements of successful applicants will be made in due course. See: https://epsrc.ukri.org/funding/calls/aicdts2018full/ for information.

The research and innovation network within the UK also draws upon their expertise and provides specialist skills training where relevant. For example: the University of Reading's Institute for Environmental Analytics creates and delivers targeted training courses to address market opportunities and the shortage of environmental analytics skills, giving companies, organisations and individuals the practical knowledge and confidence to make commercial use of the huge resource of open data. https://www.the-iea.org/services/training-development/; and the European Institute of Innovation and Technology (EIT) Climate Knowledge and Innovation Community (Climate KIC) has developed a range of online learning, professional development and graduate school programmes to build awareness and knowledge around acting on climate change https://www.climate-kic.org/programmes/education/

Q4. Are there any publicly or privately-held geospatial datasets that are currently challenging to access or use or of insufficient quality, but which you or your organisation would find valuable if these issues could be resolved? Please explain why this would be of value, and how access/quality could be improved?

Data discoverability: One of the main barriers to being able to reuse data from research is knowing what is available, gaining access to the data and

understanding whether it can be repurposed or developed into other commercial or non-commercial applications of value to businesses and society (see: https://blog.wellcome.ac.uk/2014/08/20/the-discoverability-challenge-how-can-we-make-research-data-easier-to-find-and-use/).

UKRI is committed to opening up research data for scrutiny and re-use and support the principles in the Concordat on Open Research data that recognises that research data should be made open where possible.

NERC funds a series of Environmental Data Centres to ensure long term curation and reuse of valuable data sets. The challenge is making this vast volume of data available in useable formats (NERC data holdings equate to 10-12 petabytes, this is however doubling every 2.5 years). In the past the data centres have primarily served the academic community but NERC has recognised the value of the data and has an ambition, through a data Innovation programme, to link the environmental data holdings (and expertise) to other non-NERC, non-environmental data sets, to enable more effective response to the demands of a range of users. The programme will address other issues around data, such as barriers to accessibility due to the lack of analytical tools for non experts and secure space to analyse and integrate, often large datasets from disparate sources.

In addition to those mentioned above there are non-data-related barriers to accessing and using data such as Intellectual Property Rights or licencing-related issues, including both legal and cost barriers

Facilities for using secure data: UKRI (NERC) is aware of a number of recent examples of academics not being able to access private sector geo-spatial data (e.g. infrastructure location and condition, insurance loss data), however there is an understanding that, on the most part, there are sound regulatory, security or commercial reasons. A role for the geospatial commission could be to invest in secure platforms which would enable secure data storage that would enable access for appropriate research purposes, providing facilities to combine data sets (from non-secure sources) and with access to appropriate computing power. For example, the ESRC funded Consumer Data Research Centre: https://www.cdrc.ac.uk/, Data & Analytics Facility for Infrastructure: https://www.itrc.org.uk/dafni-data-and-analytics-facility-for-national-infrastructure/

UKRI also provides access to a wide array of Satellite derived imagery through the STFC JASMIN facility for research use and the Innovate UK Satellite applications Catapult CEMS and data visualisation facilities for commercial users.

Implementation of quality assured standards
The Geospatial Commission should consider the adoption of quality assurance standards and certification schemes to support the widespread and mainstream transfer of scientific data sets for commercial applications. Much work has been done in terrestrial environmental services to understand the traceability and uncertainty indication of environmental measurements (such as the MCERTS

certification scheme (https://www.gov.uk/government/collections/monitoring-emissions-to-air-land-and-water-mcerts), supported by ISO17025 with additional requirements for operator training) to support pollution monitoring, Kyoto/inventory reporting, water/soil/land monitoring and emissions from large combustion plants. This is to a point where the data service is legally defensible and can guarantee its quality. It would be very good to see Earth Observation (EO) and geospatial data reach this level of maturity as it is much more likely that existing service providers could integrate EO and geospatial data into existing services and provide an opportunity for growth and increase market share. This does not assume that EO/geospatial data is of poor quality, but that an accepted standard/certification scheme to simply indicate the level of quality of the data product should help enable its widespread adoption in governmental and commercial services. The barriers to this are that a top down approach is required to intervene in the industry, and there is a perception that certification brings additional expense (but actually results in improved customer value, customer relationship and revenue), however the Geospatial Commission could be well placed to lead on such an activity.

The proposed Industrial Strategy Challenge Fund (ISCF) for Satellite Data Revolution is explicitly designed to adopt, develop and promote standards for satellite derived earth observation data. The Geospatial Commission is already engaged in this process, and the ISCF will simplify both the technical and commercial environment for integration of satellite derived geospatial data.

Q5: Do you anticipate that any changes will be needed to the both address data and the wider address ecosystem, to support emerging technologies? Please provide evidence of value to support any proposed changes.

Yes, UK mapping data has been at the forefront of digital integration but less so in the integration of the wider national mapping system. This is most visible in the prolific use of postcodes for navigation purposes, which can be ineffective. A variety of bespoke commercial solutions has been developed, predominantly in the satellite navigation device domain and associated smart phone apps. Other publically searchable databases are also using the postcode as a convenient identifier.

To properly support emerging technologies, an interface will be needed. Whilst a digital technical solution makes sense novel new solutions such as what3words have made significant progress in addressing the challenge in a straighforward way.

Q6: How should the commission be looking to develop the UK's capability in Earth observation data, both technologically and to support an effective market?

UKRI would welcome working in partnership with the Geospatial Commission to continue to develop UK capability in Earth Observation (EO) data.

There is already vast capability and expertise within the UK scientific community. NERC's National Centre for Earth Observation (NCEO) provides world class capability and core expertise in Earth Observation Science, data sets, merging data and model evaluation. NCEO links this expertise in environmental science with progress in the satellite technology sector and supports the exploitation of satellite data for societal and economic benefit.

Sentinel data access to the academic community is provided via CEDA (Centre for Environmental Data Analysis) hosted on the JASMIN data/computing infrastructure, NERC-funded facilities in STFC.

Note that Earth Observation data is not only 'images' – the data can be quite complex, and require sophisticated processing algorithms to convert into 'usable' information (eg from radiance spectra to ozone maps). This requires appropriate (scientific) expertise, but also data storage and computation resources.

In the recently published Value of satellite-derived Earth Observation capabilities to the UK Government today and by 2020 – July 2018 report commissioned by Innovate UK on behalf of UKRI, London Economics highlights the opportunities and challenges within government in adopting satellite derived data within the context of existing geospatial challenges. The Geospatial Commission can play a critical, coordinating role in delivering on the report's recommendations, by consolidating requirements and points of engagement with industry for EO and other geospatial data sets, and ensuring EO practitioners across government, research and academia can help government to become an increasingly well informed and proactive customer, building on the UK GEOS concept.

Unleashing the potential of vast amounts of knowledge and data from satellite Earth Observation and remote sensing into commercially viable geospatial services is also something trying to be addressed within the recent 'Space Data Revolution' ISCF Wave 3 submission. This programme aims to create a commercial marketplace for EO data, combining with AI to support useful information services across Energy, Transport, Finance and Construction sectors through collaborative R&D resulting in new platforms, services and technologies. Should the SDR programme be successful this should also be considered as an important aspect of academia and industry collaboration to support the geospatial commission in their strategic objectives. The programme being led jointly by STFC, NERC and I-UK.

As the ISCF bid sets out, the UK requires the underpinning infrastructure to enable quick and easy access to interoperable and analysis-ready data to assist both the exploitation of EO data and application innovation.

In alignment with the ISCF, the Geospatial Commission could consider working with funding entities such as Innovate UK, UKSA and ESA to drive more strategic

funding into the application of EO and AI. This could enable large scale, higher value developments with export potential.

It should be noted that there are concerns within the research community around access to EO data, following the UK's departure from the EU (see the following headlines as examples: https://www.pixalytics.com/new_uk-eo-sats-brexit/ and https://geoconomy.com/index.php/2018/03/25/uk-faces-brexit-threat-to-copernicus-participation/. It is likely that the UK Government may look at how this could be 'mitigated' and the Geospatial Commission, working with others could have a role in this.

Q7. Which new technologies should the commission focus on to provide new opportunities to process and exploit geospatial data for economic growth?

From working with business users there are some general themes, that are relevant but not necessarily specific to geospatial data, which often get raised with regards to their requirements for data:

- Data usability [getting the underlying basics right] – removing to use (data-related or otherwise)
- Data interoperability
- Digital Environment
- The need to be able to access good quality data from multiple sources and use AI to help deal with the large volumes of data available. Also using AI to help reduce R&D timescales, therefore getting from data to market much quicker (and whether it was possible to collectively develop common AI tools that could be used by all).
- Skills and the retention of skills around AI and the use of Earth Observation data, especially with regards to training up the next generation of graduates who would then go to work in industry.
- Use of Intermediate software (this is dependent on the end-user and their level of expertise)

In addition to technologies required to provide new opportunities to process and exploit geospatial data for economic growth, there is reliance in some industries on models and provision of good quality, reliable Geospatial data to incorporate into physical models (e.g. flood models, air quality models, thermal models of buildings, oil spill models). From these models specialist products and services are developed. The UK engineering and environmental consultants are world-leading in this, for example, https://www.ambientalrisk.com, http://www.aether-uk.com/, https://www.jbaconsulting.com.

Developing technologies related to personal monitoring of for example air quality, will enable the public to monitor their environment with regards to human health. Linking such data with geospatial data (both indoor and outdoor) are likely to align with the activities in exposure and disease within the MRC-Public Health England

Centre for Environment and Health.

In recent years the research councils and Innovate UK (now UKRI) have been working together on a number of collective funds, for example the Industrial Strategy Challenge Fund (ISCF, now in its 3rd wave) and more recently the Strategic Priorities Fund (SPF), for which announcement of Wave 1 projects has recently been made (see: https://www.ukri.org/news/uk-research-and-innovation-launches-major-programmes-to-tackle-climate-change-and-drive-clean-growth/. Some of which include the development of new technologies and computing techniques that are relevant to Geospatial data.

The ISCF brings together research and business to develop, demonstrate and support the adoption of new products and services. Research is based around four grand challenges, AI and data economy; Ageing Society; Clean Growth; and Future of Mobility. The "Transforming Food Production" ISCF call, which is currently open to applications, is likely to use elements of geospatial data. Successful projects will aim to 'improve productivity and sustainability by developing enhanced decisions support, precision agriculture technology solutions and systems for crop and ruminant agriculture.'[1] In addition, a proposal for 'Space Data Revolution', jointly led by STFC, NERC and I-UK has been submitted under the AI and data pillar, in Wave 3 of the ISCF (see Q6 response).

The Strategic Priorities Fund is a new collective fund across UK Research and Innovation, which aims to better enable investment in cross-departmental research and innovation priorities across UKRI, thus increasing high quality multi-disciplinary and inter-disciplinary research and innovation (MIDRI) and positioning UKRI to be able to respond to strategic priorities and opportunities. Programmes funded under the SPF include "Constructing a Digital Environment" lead by NERC and supported by EPSRC (and Defra).

Q8. How can geospatial data and applications be used to support enhanced roll-out of future technologies?

Many forms of geospatial data will rely on the application of Artificial Intelligence (AI) to roll-out at a cost that will make the associated offering commercially viable. The application of AI to innovative, value adding geospatial solutions will in many cases be key to international roll-outs. This is particularly true for the application of satellite derived earth observation data which has the inherent potential for scale, globally.

[1] https://bbsrc.ukri.org/funding/filter/2018-iscf-challenge-platforms/

Q9: What are the options for how public sector organisations could continue to invest in maintaining and enhancing our geospatial data assets?

From a NERC perspective, NERC will fund the maintenance of data generated from the environmental science that it funds, if it is deemed that the data set has long-term value. This does however come at a price and NERC invests more than £5.5M annually in its Environmental Data Centres. [*Please note that this figure is for the ingestion, management and dissemination of data ONLY, it does not include the cost of hardware, associated infrastructure costs nor energy consumption].*

UKRI are developing a UKRI Infrastructure roadmap, under which data assets are seen as a vital part of the UK infrastructure landscape.

To enable public sector organisations to continue to invest in maintaining and enhancing our geospatial data assets, the necessary levels of funding are required. Data held by the organisations within UKRI, is generally held for research purposes, however much of it is open for wider use. UKRI does not generally curate data as a service for commercial users or government more widely unless additional funding is provided. Considering this options for continued investment could include:

1. The maintenance and enhancing of Geospatial data assets are publicly funded and data is freely available to all on OGL. Funding above and beyond what public organisations currently do would need to be provided from Central Government.
2. Data is available for research and commercial R&D, under a no-fee commercial development licence, but any commercially released service would return royalties (or an equivalent) to the data providers, which would be reinvested in the maintenance and enhancement of the geospatial assets.
3. As 2, but any data used in a commercial service or product would require a commercial (paid for) licence, the funding for which would be invested in the maintenance and enhancement of the geospatial assets.

Q10: What areas of the underpinning geospatial infrastructure such as positioning technologies, including GPS and indoor positioning systems, and geodetic networks and frameworks to support them, should we be prioritising the development of, in order to support the emerging requirements for geospatial data?

Access to geospatial data is two-fold, firstly in the integration of data and secondly in its implementation “in the field”. The past decade has seen a transformation in the adoption of satellite navigation technology (or GNSS, Global Navigation Satellite Systems) at all levels of society. Predominantly this in the use of GPS but more recently the use of Galileo and EGNOS, provided by the European

Commission. Leaving the EU will limit some access to this infrastructure and the Geospatial Commission should provide a voice for the whole of the geospatial user community regarding alternative solutions, including inputting to the proposed UK GNSS solution but also alternate technologies as they reach maturity for adoption. This may include quantum technology solutions in the future but more immediate solutions exist in a variety of electronic navigation means, standard and quality control will be critical to successful adoption.

There are also civil vulnerabilities because of dependency on GNSS. These have been highlighted in a number of technical and economic studies, best encompassed by the blackett review of "Satellite-derived time and position: a study of critical dependencies" https://www.gov.uk/government/publications/satellite-derived-time-and-position-blackett-review

Expansion of monitoring networks – 'blowing up networks' for acute events (for example, flooding, air quality) through the use of cross-linked/combined networks, or the inclusion of citizen-science data (for example from wearable electronics, which could be used to monitor exposures related to human health). The terrestrial data could be used to validate/calibrate remote sensing data, or to support operational activities from delivery bodies.

Farm platforms — As underpinning infrastructure, BBSRC funds the North Wyke farm platform, which provides researchers from different communities and disciplines with access to a range of cutting-edge instrumentation.[2] The aim is to address key issues in sustainable agriculture, and data collected from the platform are publicly available.[3]

Q11: What role should the private sector have in both the development and maintenance of the underpinning infrastructure and enhancing the UK's geospatial data assets?

Generic underpinning infrastructure required to build fundamental national capability would ideally be funded by both the public sector and wider industry. The nature of the development should be shaped by relevant UK industry members. The ISCF Space Data Revolution sets out a case for this and the learning within this could be expanded to all areas of Geospatial applications.

Public-private partneships should be encouraged where there are mutual benefits to be gained. For example, the Global Earthquake Model (https://www.globalquakemodel.org/) is an excellent example of a public and private sector partnership which uses geo-spatial data to develop a global model of earthquake risk. GEM has sourced data from around the world, developed data and inter-operablity standards and offers data layers and model components

[2] http://resources.rothamsted.ac.uk/farmplatform
[3] https://nwfp.rothamsted.ac.uk/

openly to users from insurance industry to the UN.

Agrimetrics (one of four Agri-Tech Centres) uses big data to increase efficiency and sustainability in farming[4]. Founded by Rothamsted Research, the University of Reading, NIAB and Scotland's Rural College, partners include Syngenta and DEFRA. Agrimetrics have used data on varieties, solar radiation and canopy development to create a Potato Yield Model app, which is used by Asda's growers to manage yields.[5]

Q12. Do you face challenges when working with geospatial data from across the public sector? If so, what are they and how could value be better released? Are there any technical remedies or standards that could be adopted to improve the interoperability of geospatial data? Please provide supporting evidence of what these remedies could help to accomplish.

The 2018 report "Value of satellite-derived Earth Observation capabilities to the UK Government today and by 2020 – July 2018" detailed under Question 6 includes a number of case studies highlighting the barriers to adoption, some of which will be mitigated by a common federated approach.

To extract the value of geospatial data which lies in academia, there needs to be greater interaction between academia and those within business who can develop products and services. In order to do this:

- New structures/initiatives are required to address data discoverability issue and raise awareness of what data is available in academia. These must connect geospatial data producers with policy and business problem holders (for which geospatial data could help) with solution developers who will apply geospatial data in innovative ways.
- Collaborative R&D programmes are needed to support businesses as they test application and use of geospatial data for novel business applications, de-risking the development of new products.

NERC are aware that even within the domains of environmental science, data is often siloed. NERC is working with its data centres on and Environmental Data Service, which will increase integration across its data centres so that information from across the environmental domains can be more readily found, accessed and used. It is NERC's ambition to improve and encourage the use of environmental data by external stakeholders (including businesses), and as part of this enabling/facilitating integration with environmental data from other data providers. This is a focus of its developing data innovation programme, Dodona.

Interoperability of geospatial data

[4] https://agrimetrics.co.uk/home

[5] https://agrimetrics.co.uk/case-study/agrimetrics-brings-potato-yield-model-to-farmers-fingertips

The Global Earthquake Model provides one example of data standard and interoperability.

Addressing the 'quality gap' in Earth Observation (EO) data for commercial environmental services is an important aspect for the geospatial commission to consider in its increase uptake of EO data and its widespread integration with other forms of data to deliver customer value. This is because the use of EO Environmental data may fall short in terms of the level of legality, trust and certification normally required from terrestrial based services to deliver environmental services in a number of sectors including renewable energy, combustion plant monitoring, ambient air monitoring, soil/land remediation, Kyoto/carbon inventory reporting. The adoption and implementation of a certification scheme for EO data in commercial services requires a top down approach, since individual parties from both research and industry communities will not adopt a new standard if it is not widely recognised. Many of these elements have been considered within the scope of The ISCF Space Data Revolution champions the concept of data standardisation and interoperability. There is critical opportunity for the Geospatial Commission to support initiatives to harmonise data standards across and within data types within this proposal and expand the learning to all areas of digital data collection.

A good model created and adopted in the UK environmental services sector was MCERTS, which created an industry accepted standard for certification of data, instrumentation and the trained operators following the international ISO17025 standard. This had the effect of driving a quality driven industry where all environmental information is quality guaranteed, auditable and will stand up to legal interrogation. MCERTS also had other benefits including the recognition of the skilled work of the trained operators with career development opportunities, an improved commercial marketplace for customers, and a general professionalisation of what was a scientific endeavour, into a commercial industry.

Q13. How can the Geospatial Commission act as a more effective customer for geospatial data on behalf of the public sector?

The Geospatial Commission could work to connect geospatial data producers with policy and business problem holders (for which geospatial data could help) with solution developers who will apply geospatial data in innovative ways.

In doing so they could support demonstrators and provide case studies showing the breadth of applications of geospatial data.

As a customer, the Geospatial Commission could identify and consolidate requirements and standards across government and act as a point of engagement with industry. This is needed not just for procurement as such but for ongoing engagement during the R&D to operational phase in order to ensure

developments are being steered to meet requirements. There is a significant secondary value in repurposing of purchased data. At present the same commercial data can conceivably be purchased multiple times for different applications.

Greater use of existing funding instruments such as the Small Business Research Initiative (SBRI) are also recommended.

More strategic funding could enable higher value developments that would not only benefit the UK economy but could pave the way for larger international contracts.

In terms of procurement, the Geospatial Commission could enable shorter cycles in procurement processes by the use of approved suppliers, similar in concept to g-cloud, to bring about faster transactions.

Q14. Are there any additional geospatial datasets, from the other partner bodies or other sources, that the public sector would derive significant benefit from having access to, that might have novel and valuable use cases? What would that access look like?

Significant public sector geospatial data holdings are available but not currently part of the Geospatial Commission. This includes data generated by publically owned or funded research institutes, such as the Natural Environment Research Council's:

- Centre for Ecology & Hydrology (CEH)
- National Oceanography Centre (NOC)
- National Centre for Atmospheric Science (NCAS)
- National Centre for Earth Observation (NCEO)
- British Antarctic Survey (BAS)

NERC has a network of environmental data centres that provide a focal point for NERC's scientific data and information. These centres hold data from environmental scientists working in the UK and around the world. The data centres are responsible for maintaining environmental data and making them available to all users, not just NERC researchers but others from science, business and government.

It is essential that data generated through NERC supported activities are properly managed to ensure their long-term availability. The data centres are experts in the collection of scientific information, state-of-the-art data management and preservation techniques, resulting in a high quality and important national asset available to all.

The range of data held within the data centres is vast, covering all aspects of environmental science.

- British Oceanographic Data Centre (Marine)
- Centre for Environmental Data Analysis (Atmospheric and Earth observation Data, and the UK Solar System Data Centre (Solar and space physics))
- Environmental Information Data Centre (Terrestrial and freshwater)
- National Geoscience Data Centre (Geoscience)
- Polar Data Centre (Polar and cryosphere)

For example,

- UK Landcover map providing detailed coverage of vegetation and habitat types: https://www.ceh.ac.uk/services/land-cover-map-2015
- UK Lakes data is a GIS-based inventory of lakes, including typology, chemistry, biology; https://eip.ceh.ac.uk/apps/lakes/
- National River flow Archive: https://nrfa.ceh.ac.uk/
- General Bathymetric Chart of the Oceans (GEBCO) which aims to provide the most authoritative, publicly-available bathymetry data sets for the world's ocean: https://www.gebco.net/

Aside from these data centres, important assets exist in higher education institutions. For example, Cranfield University hosts the National Soil Resources Institute.[6] The Institute has produced a National Soil Map which is usable by non-soil scientists and provides evidence to enhance decision making (for example in deciding where best to grow particular crops).[7]

Q15: How can we best develop a single UK strategy, ensuring alignment between the individual strategies across the UK while still allowing for regional variations?

The single UK Strategy should provide the UK's overall direction and strategic goals for geospatial data and information (and its use / reuse). It should acknowledge where there are synergies and cross overs across the UK and where there are regional differences. Each DA can then align their own strategies to this, giving them the freedom to shape their strategies to accommodate the regional differences, but ensuring that they are aligned around the "commonalities" across the UK.

The Geospatial Commission could play a coordination function providing communication and information across the strategies.

6 https://www.cranfield.ac.uk/centres/soil-and-agrifood-institute/research-groups/national-soil-resources-institute

7 https://www.cranfield.ac.uk/case-studies/research-case-studies/national-soil-map

The Geospatial Commission also has the opportunity to bring about wider coordination and greater utilisation of particular practioners from across government, research and academia at a regional and national level. This could enable proactive, highly informed and coherent strategy development.

This type of coordination could also provide a much-needed unified point of engagement with industry, which could in turn, help inform the strategy. Maintaining a flexible approach in a common strategy also opens the opportunity for international collaboration and exports. Geospatial data may define borders but is not bound by them. Setting or adopting appropriate standards that can be applied internationally is critical for internal collaboration and UK exports and should not be limited to regional variations.

AS mentioned in Q.9 UKRI are developing a UKRI Infrastructure roadmap, under which data assets are seen as a vital part of the UK infrastructure landscape.

Q16: How can we best ensure effective local authority coordination and sharing of best practise, using location data to better deliver public services?

The creation of a geospatial forum, building on the UK Government Earth Observation Service (GEOS) concept, could enable the sharing of best practice of location data use among local authorities. This could be conducted virtually through the use of a portal and physically at an occasional conference. Demonstration is key element of coordination and adoption and whilst individual schemes exist these should be coordinated and consolidated where possible and delivered at scale to promote adoption.

Q17: As a result of this analysis, we are prioritising the exploration of possible initiatives in the high-value categories identified:

- **property and land**
- **infrastructure and construction**
- **mobility**
- **natural resources**
- **sales and marketing**

What are the existing or potential geospatial applications which could be scaled-up or developed in order to capture economic value? (We would particularly welcome responses from industry and other bodies engaged in these sectors.)

With regards to Infrastructure and Construction, Biodiversity Net Gain (BNG) could become an obligatory part of the National Planning Framework for new developments and infrastructure (over a certain size). Geospatial data would be invaluable in planning/implementing BNG to ensure a connected landscape for wildlife along 'green corridors'. Ref:
https://www.nipa-uk.org/uploads/news/WSPPB_Biodiversity_whitepaper_Copy.pdf
https://www.gov.uk/government/news/hs2-launches-plans-for-unprecedented-green-corridor-stretching-alongside-the-railway

Scale-up of geospatial data is the subject of an ISCF wave 3 bid – Space Data revolution, where such data, linked to more powerful data analytics (such as through AI), can provide greater business opportunities and economic value in numerous business sectors including transport, energy, finance and construction. As mentioned above (question 7), geospatial data will also play a part in the "Transforming Food Production" bid to increase crop and farmed animal productivity.

On natural resources, two areas of precision agriculture are especially noteworthy: precision steering and precision agronomics. There is significant growth potential in precision steering (where GPS guidance is currently used to auto-steer tractors) because GPS data is also crucial for robotic and autonomous systems in agriculture more broadly. Such developments in technology are a significant driver of growth in the global market for agricultural machinery, which has been estimated to be worth $243 billion by 2025.[8]

Precision agronomics aims to provide farmers with evidence that allows them to manage farmed species to improve yields and productivity. Since geospatial data is used to bridge the gap between the biology of individual organisms and the surrounding ecology, research in precision agronomics sits at the interface between NERC and BBSRC. Through the Sustainable Agriculture Research and Innovation Club (SARIC)[9], NERC and BBSRC have worked together to support the development of farmer decision support tools that use geospatial data. www.soilquality.co.uk combines geospatial data with geochemical datasets and biology to provide evidence for managing soil to maximise yields and minimise the presence of soil-borne pests and diseases.Other areas include the improved monitoring of crop production and modelling of crop performance. For example, the High Value Crop Monitoring (HiVaCroM) project is funded by the European Space Agency and is focused on delivering improved forecasting of potato yields through the use of satellite data , while Climate Corp, which was acquired by Monsanto in 2013 for $930M, focuses on combining data gathered on farm with landscape datasets to provide evidence for current crop health and growing strategies, such as soil management and pesticide usage.

[8] https://www.grandviewresearch.com/press-release/agriculture-farm-equipment-machinery-market
[9] https://bbsrc.ukri.org/innovation/sharing-challenges/saric/

Geospatial data is being increasingly used to monitor global forests e.g. Forests 2020, funded under the UKSA International Partnership Programme. This is aimed at addressing inadequate monitoring systems which, despite frameworks to help developing countries protect and restore their forest resources, remain a barrier to effective implementation. ESA's seventh Explorer Mission BIOMASS due for launch in 2020 has been developed by a consortia led by Shaun Quegan, Professor of Mathematics at the University of Sheffield to accurately measure how much wood is growing on Earth. Particularly important will be the ability to track forest degradation and measure the currently unmeasurable movement of carbon and other green house gasses.

As individuals, communities and a country, we are required to make multiple decisions using UK and global landscapes. A landscape is the product of environmental processes, social and cultural requirements and values, and ecosystem services associated with them. It will change continually across multiple scales (of space and time) through changes to natural systems such as water, air, climate, and biodiversity, which are themselves influenced by multiple uses and users of the landscape. All have been changing over time and interact; many are now moving faster than ever before. To understand the impacts of our use of the land on the wider environment, and to improve the sustainability of land management (including agriculture), we need interdisciplinary systems-based approaches at multiple scales (from field to farm and landscape).[10] The increased resolution (spatial and temporal) of geospatial data and the increased diversity of the type of data available will allow 'better', or more informed, decision making, but only if we are able to take new approaches that will resolve the complexity of processes and trade-offs between multiple objectives.

In addition to geospatial applications which could be scaled-up or developed in order to capture economic value, there are opportunities to link up and use remote sensing with geospatial data in the context of urban and health monitoring.

Satellite derived earth observation data is one type of geospatial data that inherently lends itself to being scaled through its application. With the advent of low cost, small satellites circuiting the earth at low earth orbit (LEO) altitudes, ongoing advancements in data quality and increasing data frequency, this type of data is becoming more valuable to a range of applications. The emerging application of AI is now the key to unlocking the potential for scale, at a viable cost, and is pointing the way to a much greater uptake of earth observation data, at scale, in the near future.

There are various projections for the value of the satellite derived earth observation market. One estimate projects the global market to be $66Bn by 2020 (GeoBuiz 2018).

[10] Achieving Sustainable Agricultural Systems (ASSIST) is a long-term National Capability programme jointly funded by NERC and BBSRC which aims to work with the farming industry to increase productivity without causing environmental damage.

Q18: Are there any other areas that we should look at as a priority?

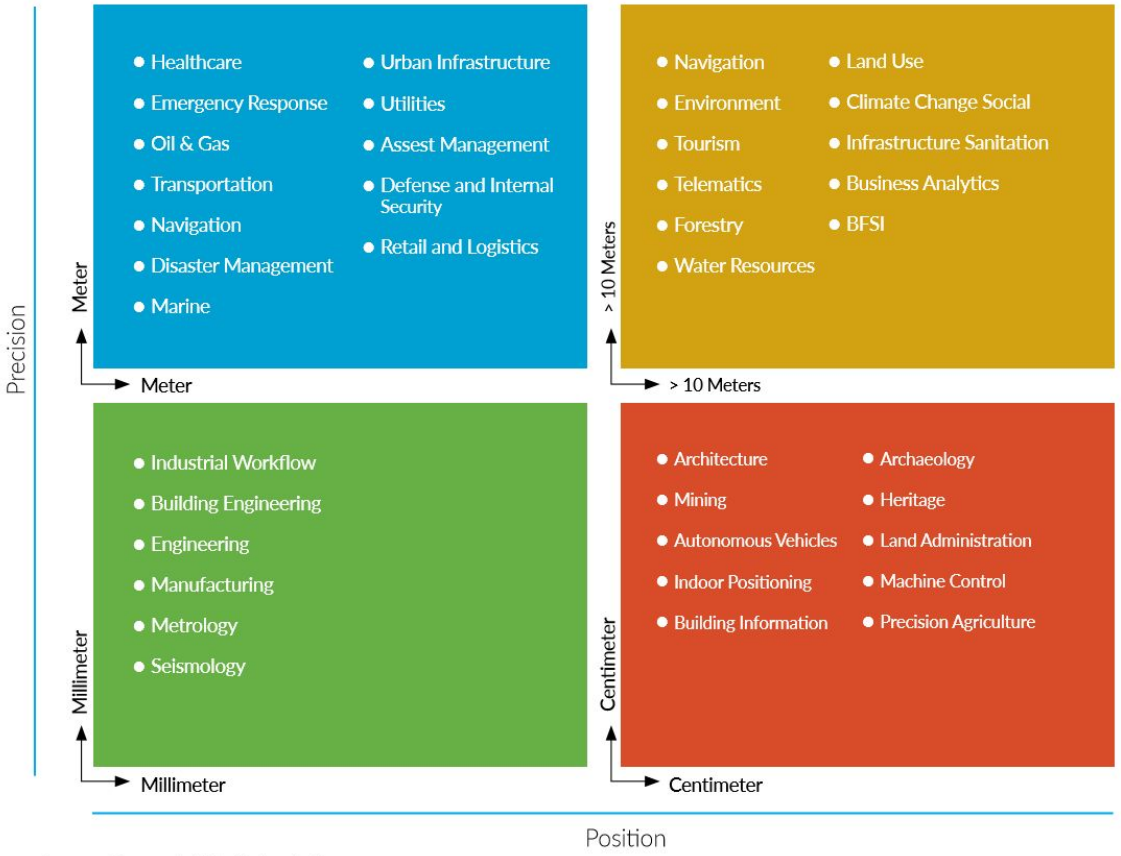
There is potential to expand on natural resources to include for example the Oil and Gas sector using geospatial data on exploration and monitoring. This could include the use of computational techniques and analytical methods, including AI or edge computing. There is a high level of adoption in this industry already and integration should not be onerous.

Green finance – and green growth – offers unprecedented opportunities for financial institutions to invest in the restoration of UK natural features such as woodland, peatland and wetland. The UK Government's **Green Finance Task Force** in March 2018 that "*increased private sector investment into protecting and enhancing natural capital will also be crucial to improving our resilience*."
Geo-spatial data has a key role in identifying, monitoring and verifying natural assets, in a similar way as it is used for REDD (e.g. https://www.planet.com/markets/redd/) .

Access to robust geospatial data is also central to managing growing climate and environmental risks through improved analytics. The demand for such a capability is increasing to reflect not only the growing exposure of public and private institutions to the physical risks associated with climate change and its impact on the probability of natural catastrophes, but also the risks associated with the transition to a low carbon economy and the associated implications for firms and investors exposed to corresponding volatility in asset values (the so-called 'stranded assets' problem identified by the Bank of England and others). At the same time, regulatory policy is increasingly requiring that firms and financial institutions make their exposure to such risks transparent so that they can be reflected in investment decisions and capital allocated efficiently (see G20 FSB Task Force for Climate- Related Financial Disclosures ("TCFD")). This in turn cannot be delivered without improved analytics and access to the data required to support this, including robust geospatial data. [This potential deficiency is the subject of a proposed ISCF Wave 3 challenge].

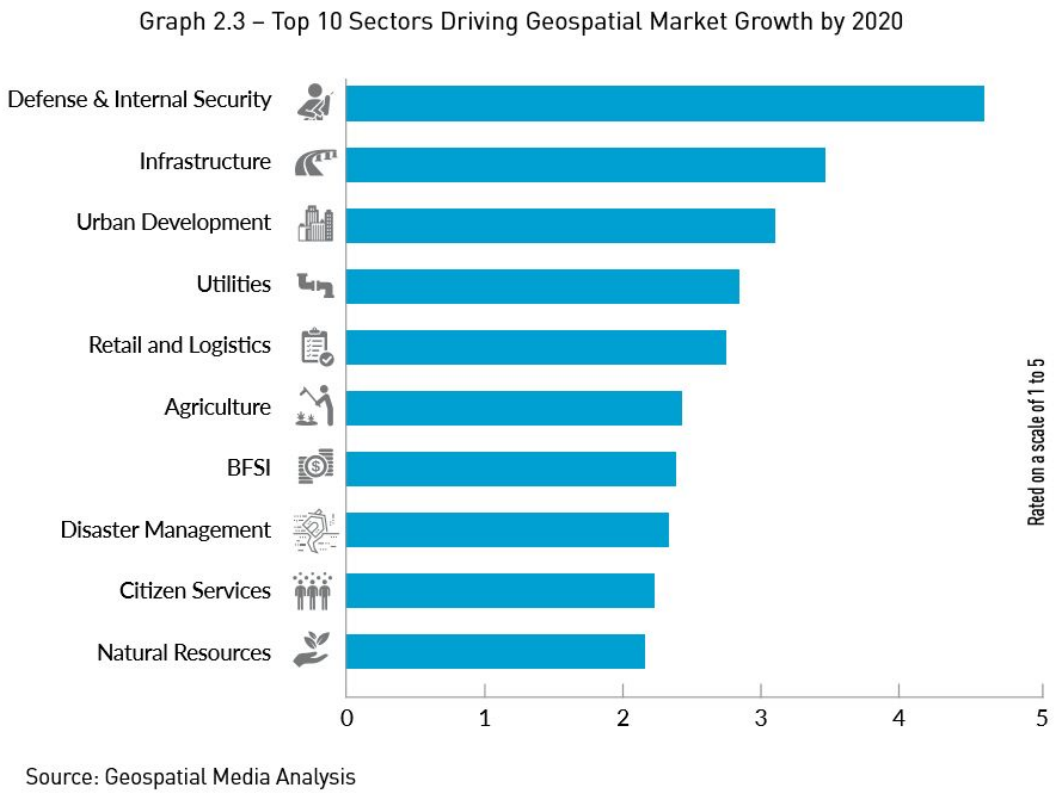
An increasing number and range of sectors are leveraging geospatial information to improve efficiency and productivity. The Geospatial Industry Outlook and Readiness report 2018 confirms that the geospatial industry is witnessing demand growth from "more and more sectors that are integrating geospatial solutions into their daily workflow management" and the automation of such.

Figure 2.2 – Geospatial Industry Applications: Position to Precision



Source: Geospatial Media Analysis

The report goes on to suggest that the top ten sectors driving near-term geospatial market growth are as follows. These include some of the high value sectors already identified by the Geospatial Commission.



A recent economic study to determine the value of satellite derived earth observation capabilities to UK government (by London Economics) identified new near-term potential in transport, (and particularly infrastructure monitoring), forestry, the built environment and coastal management and further applications in agriculture, maritime and flood management (as referenced in Question 6)

Q19: What are the main potential private and public sector innovations that will rely on the use of geospatial data to rollout, and are there corresponding regulatory challenges?

Turning the question around, many forms of geospatial data will rely on the application of AI to roll-out at a cost that will make the associated offering commercially viable.

To date we have seen a transformation in internet search capabilities to include location relevance. This impact of this is visible in retail, services and navigation or mapping but is increasingly relevant to all areas of interest. Increasingly this is being linked to identity and behaviour. An issue already seen in the telematics market. Regulation in relation to the significance of location as an identifier and how location based information is shared will require regular revision in our modern society with impacts across to wider geospatial data.

Trust and confidence in dynamic geospatial data i.e. that, which might be

changing continually, can be maintained through standards but for safety critical activity may require regulation.

The application of AI to innovative, value adding geospatial solutions will in many cases be key to international rollouts. This is particularly true for the application of satellite derived earth observation data which has the inherent potential for scale, globally.

Applying AI to earth observation data could unlock high value potential for applications in many sectors.

Q20: How best can we make the UK's presence in the international geospatial world more visible?

By leading the way in major commercial markets, internationally, the UK can become not only highly visible in the international geospatial world but can gain a competitive edge in a high growth, global market and thereby benefit economically.

This can be brought about by creating the right infrastructure, by stimulating and funding UK based innovation, encouraging and facilitating collaboration across and among academia, research and industry, and supporting scale-up and international trade from the UK. It can also be assisted, where relevant, by UK government becoming a lead or anchor customer.

Innovation support needs to be guided to particular technology developments and applications including AI to unlock the potential for scale, and to high value market areas.

Businesses then need to be supported if not incentivised to scale and address international markets, quickly. This could be enabled by applying and co-ordinating public sector funding to de-risk follow-on private investment.

Q21: Where should the UK be looking for points of comparison overseas? Who are the other international exemplars? What best practice is being modelled overseas that we can learn from?

Ultimately, from an economic perspective, it is private investment in innovation that will enable UK businesses to scale with any significance internationally. In this aspect, North America is a strong point of comparison. There are also interesting developments in Australia.
Many changes in the use and therefore demand for geospatial data come from commercial applications; which are not so specifically bound by national boundaries and may require specific horizon scanning and engagement.

Thank you for your time in completing your response to our call for evidence.

Any questions, please get in touch with the Geospatial Commission via geospatialcommission@cabinetoffice.gov.uk

Geospatial Commission: Call For Evidence Response Questionnaire

Please submit your completed questionnaire to:

geospatialcommission@cabinetoffice.gov.uk.

Clearly title your email *'Call for evidence response'*.

About you and your organisation

Name	[Text redacted]
Organisation	UK Space Agency (UKSA)
Job title	[Text redacted]
Address	[Text redacted]
E-mail	[Text redacted]
Telephone	[Text redacted]

Please select which of the following best describes you as a respondent:

Respondent	**Please mark with a X**
Academic	
Business representative / trade body	
Central government	**x**
Charity or social enterprise	
Individual	
Legal representative	
Local government	
Large business (over 250 staff)	
Medium business (50 to 250)	
Small business (10 to 49)	
Micro business (up to 9)	

Other - please state	

Call for evidence - three key themes

We have identified three high-level themes that could help our approach to setting a strategy which are as follows:

1. **Supporting innovation in the geospatial sector**, exploring how to secure cutting edge skills, the right access to data, and opportunities from emerging technologies for the geospatial sector itself
2. **Enhancing the UK's geospatial assets,** looking at how best to align interests, avoid duplication, and instill best practice across the whole public sector
3. **Driving investment and productivity in geospatial applications**, asking in which wider sectors the most value lies from better exploitation and use of geospatial data, in the UK and internationally

Our questions

Q1. Is our view of the geospatial data types accurate? If not, what should be included or excluded from this?

Yes

Q2. In addition to current government policy, what are the areas of geospatial skills where the commission could best focus, to help ensure the necessary capability within the UK for the future?

- Ubiquitous Web and Geographic Information Systems
- Earth Observation Applications (User driven)
- Building Information Modelling (BIM)
- 3D GIS
- Web GIS Application Development and Common Libraries
- Web of geospatial data
- Geospatial Database
- Open data (what it means and its principles)
- Big data storage and analysis (high performance array database principles)
- Virtualisation and Cloud (theory and practice)
- Standards in Geospatial (OGC, IETF, etc)
- FOS4G (Free and Opensource Software 4 Geography, principles and practice)
- Spatial Data Infrastructure (SDI) Development for Enterprise Applications
- Scaling and Clustering
- User Centred Design
- Cartography
- Digital Earth
- Virtual Globes and Spatial-oriented Augmented Reality
- Location Based Services and Mobile GI Applications
- Model Web
- Geospatial Workflows and Service Composition
- Geosensors Networks and Sensor Web
- Spatial Data Infrastructures: Data and Service Sharing
- Future Internet, Linked and Open Data and the Semantic web
- Geospatial Analysis and Visualization
- Volunteered Geographic Information and Community Observatories
- Crowdsourcing
- Co-creation and Participatory GIS
- Data Mining and Knowledge Discovery
- Data Acquisition
- Modelling, and Analysis
- Uncertainty and Error Propagation
- 3D Modelling, Analysis and Visualization
- Data Security

Many of the skills listed above are in short supply in the UK geospatial industry. Only by targeting the technologies and skills above at a grassroots level will the UK avoid a growing skills shortage.

Driving skills in the UK (at a grassroots level) will require the development of a skills programme that will target secondary education and academia, not just to engage and promote the cross-cutting nature of skills required by the geospatial

sector but to provide the ability to influence and direct through leadership in the area.

Addressing skills coupled with delivery and customer focussed development, could see a step change in the UK use of satellite data. The UKSA and the Geospatial Commission should work together with other stakeholders to achieve this.

Q3. What are the geospatial skills needs and gaps in your organisations, how can these be most effectively addressed, and how can careers in the sector be best promoted?

The UKSA itself is not an organisation that operationally delivers geospatial services, however it has an overarching understanding of satellite Earth observation, how this plays into the wider Geospatial community,the associated technologies and what others in the commercial, academic and public sector need to do to use the data.

Our Space for Smarter Government Programme (SSGP) already runs an “Introduction to Satellite Applications for the Public Sector (ISAPS)” course to raise awareness of the role that space data and services has in public sector delivery. The 1-day course is delivered free of charge to public sector attendees in order to raise awareness of the opportunities offered through space solutions to public sector problems. As well as raising general/basic awareness with policy professionals and senior leaders, SSGP engagement indicates that further training interventions would be beneficial, including the inclusion of targeted specialist space data and services for Government professional functions such as data science and geography. As well as a lack of understanding of the role Earth observation can have in public sector delivery, the risks and constraints of underpinning technologies in common use which are reliant on PNT (Position Navigation and Timing - such as GPS) in applications/services across the public sector are not well understood.

The Space Sector is predicted to expand by some 40,000 new roles by 2030, the majority of which will be in the management, use and manipulation of data, requiring a solid foundation in the skills and topics described above. In order to support the development of the pipeline from school, through university or vocational training into a career in the sector, best practice examples from other areas need to be utilised. For example, these include the provision of digital datasets for the A Level Geography curriculum, support for teacher training to deliver this, relevant role models on careers platforms and visiting schools and universities, provision of real-world challenges for undergraduate and masters projects, consideration of vocational training routes (possibly including Degree Apprenticeships), and provision of quality work experience and internships.

Bolstering education opportunities and outreach, expanding existing training on a

wider scale and the inclusion of specialist space data and services within mass training for professional functions within government would help address skills gaps. UKSA already has a role in the delivery of these approaches in relation to the space sector and would like to explore scaling these areas further with the Commission as there is potential to enable some “quick wins”.

Q4. Are there any publicly or privately-held geospatial datasets that are currently challenging to access or use or of insufficient quality, but which you or your organisation would find valuable if these issues could be resolved? Please explain why this would be of value, and how access/quality could be improved?

Within the industry, generally, there has long been a challenge of access to geospatial data. Various initiatives both nationally and internationally have been introduced to improve the position. More specifically within the space sector, Earth observation data has long been the preserve of academic institutes, national government organisations or private industry and has therefore been challenging to access. With the advent of the European Commission Copernicus programme, access to data has improved but historically access to satellite derived data has always been something of an afterthought. For example, an organisation such as CEDA (Centre for Environmental Data Analysis) with funding constraints may not have been able to consider data access for commercial companies as a high priority.

The Sentinel Data Access Service (SEDAS) is a UK portal for accessing free Earth observation data from Copernicus. Initial funding was provided by the UK Space Agency to establish this capability and operate for 2 years. Funding to sustain and improve operation is based on commercial revenue generation via the Satellite Applications Catapult.

Analysis Ready Data (ARD) is the concept of processing Earth observation data to a set standard. Processing the data in this way for use across many user communities supports the uptake of Earth observation data by removing some of the associated overhead and specialist skills needed by each user. Copernicus data, specifically from Sentinels 1 and 2 already have developing standards for ARD products in other countries and the benefits are being widely felt. In the UK we don’t currently have a centralised system for the production of ARD and support for the adoption of standards could provide many benefits for government and the private sector by lowering the barrier to entry for innovators in Earth observation.

Maintaining access to Copernicus data forms part of the UK Space Agency EU exit mitigation planning. We would be keen to work with the Commission on this topic.

Q5: Do you anticipate that any changes will be needed to the both address data and the wider address ecosystem, to support emerging technologies? Please provide evidence of value to support any proposed changes.

Having a consistent source of reference for addressing data in the UK is key to the development of downstream applications for the Earth observation and location based services industries. With the development of Address Base Plus a better source of data is available than ever before, however to see improvements at scale in the way the industry consumes the data, web services need to be made available to aid the fusion of satellite derived data and terrestrial address data.

Forming these connections between the satellite derived and terrestrial systems is essential for the benefits and impacts to be fully realised. Government intervention is required in some areas to ensure that “geospatial” truly means **all** data with geographic reference regardless of source. Satellite derived data is just another geospatial data set, but it has the ability to provide information at an incredible level of detail, over huge areas, repeatedly and consistently and at an ever-increasing frequency. The inclusion of satellite derived products should not be as a bespoke service unsuitable for increased scale but a staple of any project, programme or initiative that requires a level of monitoring, connectivity or location-based service.

The UKSA would be part of the solution but it will need a coordinated vision and commitment to an infrastructure over the medium term if the UK is to retain its world leading position in Earth observation data use. See Q6.

Q6: How should the commission be looking to develop the UK’s capability in Earth observation data, both technologically and to support an effective market?

The vision agreed by the UK Earth observation community is: "*The UK will be a world leading access point for global users, providing trusted, quality assured satellite derived products and delivering growth over the long term by maximising the exploitation of EO data and services by public, academic and private sector users, through a reliable, open, secure and sustainable capability.*"

The current scene in the UK with regards to Earth observation data is rapidly evolving. Due to the way the UK operates and/or funds its Earth observation capability, pockets of activity occur between publicly funded organisations such as UKSA, Innovate UK and RAL Space, not for profit organisations part funded by Government (such as the Satellite Applications Catapult) and industry (through major primes or the plethora of Small Medium Enterprises working in the downstream EO applications field).

There is a need for strong coordination between the organisations that run the national infrastructure of Earth observation data, and for investment and consolidation in effort. The UK has the capability to lead globally in the advancement of supporting and dissemination technologies such as storage and processing capability, Analysis Ready Data/Data Cubes, common architecture that is interoperable with systems across Europe and world-wide and trusted quality assured data (calibration and validation).

UKSA would welcome the opportunity to talk about any decisions which need to be made and the roles respective organisations play in order to best serve national interest and ensure effective prioritisation

In terms of developing the pull from government stakeholders and the enabling industry to meet those requirements, a lack of awareness/understanding of what Earth observation can do or be used for, an inability to articulate user requirements, a lack of understanding of the ongoing costs associated with current ways of working and the lack of appropriate routes to market are all potential blockers to be addressed.

The Agency's Space for Smarter Government Programme has been working to create a market for EO within Government, and although considered a successful programme, the level of funding and resources assigned (£1.5m pa) prevent it making the organisational and transformative changes that are required to be enabled across Government.

Currently there is no universal way of government to centrally procure commercial satellite data or services from industry, which can lead to either a compromised service, the end users' requirements not being met, or no service being procured. The commission should be looking at a cross government procurement methodology that enables the uptake of Earth observation data and services. A model like that adopted by the Digital Marketplace which has the flexibility to buy data, services and expertise and a combination of these, with agile pull through of applications from development programmes should be considered

Q7. Which new technologies should the commission focus on to provide new opportunities to process and exploit geospatial data for economic growth?

There are many technologies that are influencing the direction of travel for the geospatial community and a lot of them focus on end user interaction rather than processing. However, a number such as:

Big Data analytics
Machine learning and AI
Data Cube technology (multi-dimensional array database structures for spatial temporal analysis)
Computer vision.
Distributed computing.
Linked data technologies and the web of data
Semantic web technologies
Sensor Web
IOT (internet of things)

provide foundation technologies that will enable the next generation of geospatial applications.

Q8. How can geospatial data and applications be used to support enhanced roll-out of future technologies?

Geospatial data and applications are at the core of what we believe to be future technologies, from autonomous vehicles, to food production and energy generation, geospatial data will underpin the way in which we interact with the environment we live in. Due to the underpinning nature of the geography any acceleration in the development of geospatial technologies is only going to increase the rate at which other technologies can be developed and adopted.

Firstly, we need to consider how the data is stored and how it can be consumed. Infrequently updated data, that is prone to having multiple versions even within a single organisation and relies on the user downloading or receiving on physical media is not suitable for advanced applications or technologies as systems rely upon consistence to enable any sort of automation. From this we can conclude that geospatial data needs to be stored in a structured and accessible format and disseminated in line with appropriate standards through APIs to enable data to be connected or linked to other data. Next, we need to think about the interoperability of data and the ability to fuse and process data into a form that can be consumed by the intermediary or end user technology and potentially passed on to complete the awareness triangle of locate, sense and inform. All the above can be achieved but it relies upon the systems, standards and openness to enable it.

Exemplar industries that would benefit from enabling geospatial data and technologies are nuclear new build, the construction and future housing industry, and national infrastructure, all of which have programmes of technology roll out. The National Infrastructure Committee will also have many examples where geospatial and space technologies will enable development.

Q9: What are the options for how public sector organisations could continue to invest in maintaining and enhancing our geospatial data assets?

Investment in maintaining and enhancing geospatial data and assets is crucial and should be appropriately funded. More than that - it should be at the core of what government wants to achieve with a clear collective view about the scale of the government activity required and the role of government in this arena.

Geography and geospatial data have the ability to transform and enhance all public services whether it be satellite derived or terrestrial, and neither in isolation will have the impact of both together.

[Text redacted]

Previously the focus of funding bodies has been on demonstrating capability in the market. Innovation programmes need to focus on the service development and change management elements of adoption in order to embed these services longer term.

Q10: What areas of the underpinning geospatial infrastructure such as positioning technologies, including GPS and indoor positioning systems, and geodetic networks and frameworks to support them, should we be prioritising the development of, in order to support the emerging requirements for geospatial data?

The focus of this question is possibly more about " "What areas……. should we be prioritising the development of, **to enable geospatial data to meet the emerging requirements of the end user community**".

Underpinning geospatial infrastructure should focus on enabling the following suit of technologies.

Big Data analytics
Machine learning and AI
Data Cube technology (multi-dimensional array database structures for spatial temporal analysis)
Computer vision.
Distributed computing.
Linked data technologies and the web of data
Semantic web technologies
Sensor Web
IOT (internet of things)

Q11: What role should the private sector have in both the development and maintenance of the underpinning infrastructure and enhancing the UK's geospatial data assets?

The private sector does have a role in the development and maintenance of the underpinning infrastructure. Government investment in maintaining technical skills within the departments and developing new skills in technical and geospatial infrastructure could allow for greater impact by enabling industry to focus on innovation of the output from the infrastructure and delivery value through end user services rather than data management and maintenance.

As any infrastructure is developed the business model which surrounds that should be carefully assessed to ensure sustainability.

Where underpinning infrastructure could be interpreted as upstream such as satellites or positioning then private sector has a key role.

Q12. Do you face challenges when working with geospatial data from across the public sector? If so, what are they and how could value be better released? Are there any technical remedies or standards that could be adopted to improve the interoperability of geospatial data? Please provide supporting evidence of what these remedies could help to accomplish.

There can be challenges when accessing geospatial data from the public sector as there is a widely adopted set of standards (adaptations of OGC, Open Geospatial Consortium, standards) that are not universally implemented. Funding a minimum set of requirements would achieve a greater level of consistency

In addition, a lack of awareness of the role space plays in GIS causes resistance to uptake. Satellite derived data is generally thought of as exotic, difficult to work with or expensive, however satellite derived data underpins most geospatial technologies and data. Even within GIS departments it would be helpful to have a better understanding of geospatial data acquisition and Earth observation i.e. the different types of sensors and what they are capable of, their limitations and how the data is captured.

Our Space for Smarter Government Programme developed a new course to try and overcome this lack of awareness/barrier, which could be scaled for additional stakeholders across the public sector with suitable funding and resources.

Q13. How can the Geospatial Commission act as a more effective customer for geospatial data on behalf of the public sector?

There are lots of programmes in government that could offer lessons learnt here.

The Space for Smarter Government Programme, having just completed a high-resolution procurement of Earth Observation data for R&D purposes for use across Government, has understood the challenges in being an effective customer and would be happy to share this experience with the Commission.

The Geospatial Commission can act as a more effective customer of geospatial data by:

- understanding the requirements of government when purchasing;
- ensuring a minimum set of skills is present in Government to ensure effective use of the data is achieved;
- developing and ensuring that an effective and efficient purchasing methodology exists that enables the market place to engage effectively with Government;
- ensuring that licencing requirements are appropriate for the use. If licensing is too prohibitive it will stifle the ability to innovate;
- purchasing certain key data sets and software tools centrally to ensure consistency across all of government and reduce any risk of duplicating spending.

Again, the potential impacts of UK losing access to some of the EU Copernicus programme data will also drive thinking in this area.

Q14. Are there any additional geospatial datasets, from the other partner bodies or other sources, that the public sector would derive significant benefit from having access to, that might have novel and valuable use cases? What would that access look like?

Historic climate records and readings from the Met Office.
Geological Maps from the BGS
Better access to data from CEDA (Centre for Environmental Data Analysis) and NODC (National Oceanographic Data Centre)
Land Parcel Information System (LPIS) data from the Rural Payments Agency
Communications networks such as Broadband and mobile telecoms.
Local Authority Data, such as planning and development, health care and services.
Healthcare data could support many applications to support efficient and effective healthcare.
UK Environmental Observation Framework Catalogue – this contains numerous environmental monitoring data sets - which are already available but could benefit from more promotion and centralised investment

As a proportion of the data above is dynamic, ensuring this data is released through continually live webservices would support novel applications.

Access to Copernicus data through live webservices and data processing infrastructure such as a data cube, would support new applications in the Geospatial Industry.

Q15: How can we best develop a single UK strategy, ensuring alignment between the individual strategies across the UK while still allowing for regional variations?

Developing a single strategy across the Geospatial landscape is never going to be easy as the ecosystem is complex.

Firstly, there is need to identify what are the blockers to use, and therefore growth, and what are the enablers. Once opportunities are identified, a set of principles needs to be drawn up. The diverse nature of the industry and the users means it is easier to adopt a set of principles across multiple strategies rather than stipulating a suit of technology or standards. This approach also allows for regional variations.

Identifying the blockers that - with some effort - can generate enablers, breaks the strategy down into bite sized chunks. For example, skills, procurement, and lack of consolidated infrastructure are three areas that can be addressed, and a programme of work to improve these elements could be planned in achievable and timebound objectives.

There is also a need to fully understand the landscape of geospatial within the UK. There are a lot of stovepipe activities in the UK and several organisations that provide R&D funding and innovation centres (such as the Geovation Hub and Catapults).

Any strategy that is developed would need to consider the development of the professions in Government (policy, geography, data science) and skills development such as the Centre for Doctoral Training in Geospatial that has been proposed by Newcastle and Nottingham universities and other initiatives such as NCEO (National Centre for Earth Observation).

Q16: How can we best ensure effective local authority coordination and sharing of best practise, using location data to better deliver public services?

It may be appropriate to fund key initiatives centrally and possibly consider mandating certain requirements if there is a clear case to do so.

SSGP has encountered common issues affecting multiple local authorities and there is no obvious route/mechanism for engaging centrally to scale these applications nationally in a way which enabled sustainable services to be developed.

The approach needs to be consistent nationally to unlock potential and achieve benefits. Identifying the data sets that will have the highest impact in terms of local authority effectiveness and industry impact, and then looking to fund those centrally should be considered.

The Space for Smarter Government Programme understands from the experience of the 100/1 project (which looked at generating affordable applications for local authorities) that for an application to be adopted, it needs to be affordable and for that to happen it must be designed for local authority use but rolled out at a scale of economy.

Q17: As a result of this analysis, we are prioritising the exploration of possible initiatives in the high-value categories identified:

- **property and land**
- **infrastructure and construction**
- **mobility**
- **natural resources**
- **sales and marketing**

What are the existing or potential geospatial applications which could be scaled-up or developed in order to capture economic value? (We would particularly welcome responses from industry and other bodies engaged in these sectors.)

In addition to the sectors above, the UKSA has been funding projects for several years through the:

Space for Smarter Government Programme (SSGP) - a programme that facilitates, investigates and demonstrates the use of satellite derived services in Government. It is currently working on themes associated with Disaster Risk Management, Emergency Services and Infrastructure.

International Partnership Programme (IPP) - a programme that funds (through Overseas Development Assistance funding) the development of satellite derived services to support developing countries.

ESA Advanced Research in Telecommunication Systems (ARTES) - ARTES, transforms R&D investment into successful commercial products and services by offering varying degrees of support to projects with different levels of operational and commercial maturity.

Each of these programmes has successfully demonstrated how satellite derived geospatial applications can provide benefit to the user and several of them fit into the priority areas identified by the Commission. A list of the applications with a brief description can be provided on request.

Other high value sectors would be:
BFSI (Banking, Financial Sector and Insurance) and healthcare.

Q18: Are there any other areas that we should look at as a priority?

As significant proportions of Local Council and national budgets are spent on Health and Social Care, significant benefits could be achieved by including this as a focus area. A competition to explore the role of satellite applications within the NHS is currently underway through the ESA Business Applications Programme.

Other high value sectors would be:
BFSI (Banking, Financial Sector and Insurance)

The UK Space Agency works closely with our industry and the space sector is well positioned to provide a market view. One approach to the public sector could be to look at the Governments top issues and risks and see whether there are additional roles for geospatial data which it isn't already meeting.

Q19: What are the main potential private and public sector innovations that will rely on the use of geospatial data to rollout, and are there corresponding regulatory challenges?

UAVs
Autonomous vehicles
Space-Launch
Digital Twins
5G
High Speed Rail
Smart IoT devices and Ubiquitous Sensors.
High Altitude Platforms
Automated infrastructure.
BIM (Building Information Models)

Q20: How best can we make the UK's presence in the international geospatial world more visible?

By investing in skills and infrastructure that enables the UK to seriously engage on the international platform. There are many international bodies and we are members of many of them but there needs to be an investment that enables the UK to do more away from the meetings and groups but works towards the goals of the international teams.

This will bring influence and presence in the international geospatial world. For example, with:

Committee on Earth Observation Satellites (CEOS)
Group on Earth Observations (GEO)
European Space Agency (ESA) bodies
Open Data Cube Initiative (ODC)
Open Geospatial Consortium (OGC)

Through investments in programmes such as IPP (International Partnership

Programme) the UKSA has made significant steps towards engaging in the international Overseas Development Assistance (ODA) community, and this has opened opportunities to work with key international organisations such as Geoscience Australia. However, more work and investment is required to maintain these relationships and our influence.

The UK government needs to be bold, confident and invest in operational services. This is an area where the UK can step forward on the international stage as all countries struggle with it.

As an example, SSGP believe the UK nuclear industry could be an example where the UK Government could provide real visible leadership and mandate that all new build generation and disposal facilities monitoring by UK regulators will include satellite derived geospatial data in their future inspection regimes. This is a bold move and one which would stimulate further application development with the potential for export overseas.

The UK also has a significant role in Disaster Response, through government involvement in international organisations such as the International Charter: Space and Major Disasters and through charities, such as Map Action which is run from the UK and actively provides on-site emergency mapping for disasters globally.

In summary:

- The UK needs to have sustained engagement with the international forums that drive the development of technology, application and ultimately growth.
- The UK needs to double its efforts in developing sustainable, operationally services that exploit the great technical foundations the UK has developed in geospatial and other satellite derived services.
- Finally, the UK needs a coordinated effort to direct the export of opportunities developed through the previous points.

Q21: Where should the UK be looking for points of comparison overseas? Who are the other international exemplars? What best practice is being modelled overseas that we can learn from?

The US has a good history of development and adoption.

Singapore also rates high as an international exemplar as does Germany, the Netherlands, China, Canada, Denmark, Switzerland and France, with Australia and Poland rapidly improving capability.

The UK is in a strong position to remain a leader in the development of Geospatial capability, but this will only remain the case with sustained investment in space and the wider geospatial sector.

Thank you for your time in completing your response to our call for evidence.

Any questions, please get in touch with the Geospatial Commission via geospatialcommission@cabinetoffice.gov.uk

Geospatial Commission: Call For Evidence Response Questionnaire

Please submit your completed questionnaire to:

geospatialcommission@cabinetoffice.gov.uk.

Clearly title your email *'Call for evidence response'*.

About you and your organisation

Name	[Text redacted]
Organisation	UKspace Earth Observation Committee
Job title	[Text redacted]
Address	[Text redacted]
E-mail	[Text redacted]
Telephone	[Text redacted]

Please select which of the following best describes you as a respondent:

Respondent	**Please mark with a X**
Academic	
Business representative / trade body	**X (see below)**
Central government	
Charity or social enterprise	
Individual	
Legal representative	
Local government	
Large business (over 250 staff)	
Medium business (50 to 250)	
Small business (10 to 49)	
Micro business (up to 9)	

Other - please state	

This response is being submitted by the Earth Observation Committee (EOC) of UKspace, the trade association of the UK space industry

UKspace has a mission to promote the best commercial, political and public environment for the UK space industry. It includes in its membership companies from across the whole spectrum of space activities with large, small and start-up organisations represented.

The UKspace EOC includes representatives from the following UK organisations that are actively engaged in Earth Observation (EO) business:

- AB5 Consulting
- Airbus Defence & Space
- APC Technology Group
- Barum and Dewar
- CGI
- Cherry Space
- Deimos Space
- Earth-i
- Geomatic Ventures Ltd.
- Geoseren Ltd.
- GMV UK
- Goonhilly Earth Station
- InSpace Consulting
- JCR Systems
- National Physical Laboratory
- RHEA Group
- Satellite Applications Catapult
- SciSys
- Serco
- Space Connexions Ltd.
- Teledyne e2v
- Telespazio Vega UK
- Tessella
- Thales Alenia Space UK

We fully expect that most of these organisations will submit their own individual company responses to the Geospatial Commission consultation as well.

List of abbreviations used

ARD	Analysis-Ready Data
CEOS	Committee on Earth Observation Satellites
GEO	Group on Earth Observations
GIS	Geographical Information System
GNSS	Global Navigation Satellite System
GPS	Global Positioning System
EO	Earth Observation
EOC	Earth Observation Committee
HAPS	High-Altitude Pseudo-Satellites
ISCF	Industrial Strategy Challenge Fund
NCEO	National Centre for Earth Observation
NERC	Natural Environment Research Council
OGC	Open Geospatial Consortium
R&D	Research and Development
SBAS	Satellite-Based Augmentation System
SEDAS	Sentinel Data Access System
STEM	Science, Technology, Engineering, Mathematics
STFC	Science and Technology Facilities Council
UKSA	United Kingdom Space Agency
UN-GGIM	United Nations Committee of Experts on Global Geospatial Information Management

Call for evidence - three key themes

We have identified three high-level themes that could help our approach to setting a strategy which are as follows:

1. **Supporting innovation in the geospatial sector**, exploring how to secure cutting edge skills, the right access to data, and opportunities from emerging technologies for the geospatial sector itself
2. **Enhancing the UK's geospatial assets,** looking at how best to align interests, avoid duplication, and instill best practice across the whole public sector
3. **Driving investment and productivity in geospatial applications**, asking in which wider sectors the most value lies from better exploitation and use of geospatial data, in the UK and internationally

Our questions

Q1. Is our view of the geospatial data types accurate? If not, what should be included or excluded from this?

The definitions of geospatial data, positional data, and geospatial identifiers look OK. We would suggest that "geospatial services" should rather be "geospatial *products and services*" to include the outputs of the services. Key to us is the inclusion of satellite Earth Observation data in its different forms, including very high resolution video and still imagery from satellites, but also extending to data from high-altitude platforms (HAPS) and drones and in-situ networks of sensors such as traffic monitoring and air quality sensors. The definition should also extend to geo-located information from social media, mobile devices, news feeds, weather forecasts, climate models and similar.

Q2. In addition to current government policy, what are the areas of geospatial skills where the commission could best focus, to help ensure the necessary capability within the UK for the future?

The commission should focus on inspiring the next generation of geospatial and Earth observation data engineers and scientists. A programme of outreach into schools and universities to promote careers in this domain would be welcome, perhaps done in partnership with the UK Space Agency.

Sponsorship of postgraduate courses and programmes that enable STEM graduates to acquire specific geospatial and Earth observation data handling and

analysis skills would be valuable, as would sponsorship of industrial placements or apprenticeships in this field.

In particular, computer science graduates need to be skilled up in geospatial data processing, as many future apps will likely include a geospatial element; and in developing more user friendly interfaces to interact with geospatial data, to reduce the level of specialist skills and expertise needed in the end-user community to extract value from geospatial data.

In the mean time, there is also a need for education or reskilling of the end-users, particularly in the public sector, so that civil servants can make the best use of geospatial data in their departments and agencies.

Q3. What are the geospatial skills needs and gaps in your organisations, how can these be most effectively addressed, and how can careers in the sector be best promoted?

A key obstacle to growth of our member organisations has been the availability of talented engineers and scientists with relevant geospatial data analysis skills. Key gaps include:

- Geospatial data scientists
- Geographical information system (GIS) experts
- Earth observation data analysts / data scientists
- Earth observation data processing engineers
- Experts in big data analytics and application of machine learning and artificial intelligence to geospatial data.
- Programmers and software architects with geospatial data processing and applications development expertise

We are aware that the MOD invests significantly in training in geospatial data analysis skills (for example at the Royal School of Military Survey). It would be useful to connect trained personnel who are looking to leave the MOD with relevant opportunities in industry that are able to make use of this training.

Q4. Are there any publicly or privately-held geospatial datasets that are currently challenging to access or use or of insufficient quality, but which you or your organisation would find valuable if these issues could be resolved? Please explain why this would be of value, and how access/quality could be improved?

The full value of Earth Observation data is only realised when analysed in conjunction with complementary public or private geospatial data sets. The UK lacks a coordinated data access solution that can bring together such data sets

and make them easily and operationally accessible to industry for exploitation. This includes for example existing governmental geospatial data such as from the Ordnance Survey, Hydrographic Office, British Geological Survey etc.

UK has invested piecemeal in various initiatives including UKSA investing in access to Copernicus Sentinel data via the SEDAS hub and STFC investing separately in the JASMIN facility which is predominantly for NERC use. None of these are suitable for full operational use (e.g. no out of hours support).

We would prefer to see the UK take a more holistic approach rather than investing piecemeal in disparate elements of a solution, and ensure that the infrastructures are designed and operated as fully operational systems meeting commercial service level standards for big-data infrastructures. The Geospatial Commission can play a key role here in coordinating the UK national approach to this.

At the same time, we recognise that there would be a cost to government for making geospatial data easily and freely accessible, and the cost needs to be justified by the benefits. We would support an evidence-based approach to data release and management that would allow government to experiement with putting parts of data into the public domain for industry to exploit on a trial basis, before committing to the full cost of release and maintenance.

Another area for the Commission's attention is how effectively the UK is making use of INSPIRE (https://data.gov.uk/inspire) to address some of the issues of geospatial data discovery, accessibility and interoperability that the UK is facing, and how effectively the UK Location initiative (https://data.gov.uk/location) is using INSPIRE.

Q5: Do you anticipate that any changes will be needed to both address data and the wider address ecosystem, to support emerging technologies? Please provide evidence of value to support any proposed changes.

We recognise that some applications could benefit from such changes but we are not in a position to assess these in detail, as address data is not extensively used in Earth Observation based geospatial services currently. There are likely to be several future applications that will rely on more precise address data, for example building subsidence or flood risk for insurance purposes, as these services need to be linked to individual buildings rather than postcodes alone which are relatively coarse.

Q6: How should the commission be looking to develop the UK's capability in Earth observation data, both technologically and to support an effective market?

As per Q4, we would welcome a holistic approach to geospatial data access for the UK, which would bring together diverse satellite and terrestrial geospatial data sets along with the necessary storage and processing capacity, the tools to exploit the data, access to expertise and know-how, and the means to deliver resulting services to customers in the commercial and government sectors. These efforts should be joined up across the Geospatial Commission, the UK Space Agency (which is examining options for UK EO Data Access), the UK Space Sector Deal, and the ISCF Wave 3 "Space Data Revolution" challenge proposal, to enable an effective and coherent market for the UK.

Another key role for the commission would be to organise and coordinate the UK government's needs for geospatial information – essentially acting as 'intelligent customer' for geospatial information services on behalf of the UK government. This would enable industry to act as 'intelligent supplier' investing in key areas to meet government needs. If geospatial services can be operationally proven at significant scale with UK government users, UK industry will be in an excellent position to export the same services to governmental customers globally.

We would also ask the Commission to strongly support the efforts being made within the UK Space Agency and DEXEU to ensure that the UK remains a full participant in the EU Copernicus programme post-Brexit. Operational access to the free and open data from Copernicus is in itself of value to the UK, but the ability to participate in industrial contracts and to have a say in the future direction of the programme would provide immense additional value, for example in delivering future EO data sets that meet UK policy needs and priorities.

Q7. Which new technologies should the commission focus on to provide new opportunities to process and exploit geospatial data for economic growth?

If the UK continues to rely solely upon free and open data sources provided by Europe or other countries, we will never differentiate ourselves from any other nation vying for economic growth in this domain.

We see the biggest potential for economic growth coming from the exploitation of near-real-time, very high resolution, global data which can unlock the insights that help business and governments to make better, more timely decisions. This needs to be coupled with integration of new technologies (big data analytics, artificial intelligence, machine learning, data mining etc.); and development of user-friendly access and interfaces (including visualisation and interaction tools) to maximise derived benefit from the data.

As such, we would encourage the commission to support the growth and

evolution of the UK's capability to acquire and exploit its own very high resolution, near-real-time geospatial data sources, in particular focusing on technologies that give the UK a unique proposition – such as satellite video constellations, small radar constellations, thermal infrared sensors, hyperspectral sensors and other evolving technologies that build on UK industrial and research strengths and can differentiate us. We do not mean that UK government must build such systems itself, but should rather create the conditions whereby the private sector is able to invest in such technology development, by helping to mitigate the risks, be they in technology development, market uptake or raising of venture capital.

Another key differentiator for the UK is its reputation and ability to deliver trusted data with known heritage in terms of quality and integrity, and this is an aspect of UK capability that can be supported and promoted by the Geospatial Commission.

Q8. How can geospatial data and applications be used to support enhanced roll-out of future technologies?

Geospatial data and applications are already helping to transform many areas of industry and government, in areas such as in agriculture, transport, energy, conservation of natural resources, and responding to natural disasters. However there are many new applications of geospatial data that are yet to be conceived, for example in smart cities, smart energy, autonomous vehicles and more.

To support enhanced roll-out of future technologies, it is essential to make it easy for industry and researchers to access geospatial data and apply it in new areas of government and commerce. Geospatial data can also benefit from the application of new technologies such as AI and big data, 5G networks, etc.

It is also essential to invest in R&D of new applications and support the transition of that R&D in to demonstrations and onwards in to commercial applications. All future technology roll outs will need to have a geospatial component – EO needs to be part of this, or the UK will get left behind.

Q9: What are the options for how public sector organisations could continue to invest in maintaining and enhancing our geospatial data assets?

Many public sector organisations in the UK invest in their own infrastructure to maintain their geospatial data sets. This includes commission partner bodies (UKHO, BGS, OS etc.) as well as others such as the Met Office, STFC, Defra, several universities, NERC research centres (such as BAS and NOC) and the Satellite Applications Catapult, for Earth Observation data.

This approach tends to result in 'stovepipes' of geospatial data dispersed around

the country, each with different formats, standards, accessibility, licensing etc. The UK open data policy mandates public sector organisations to make all non-personal data available openly but each organisation is at a different stage of implementing this policy and it is particularly challenging for industry, academics or government bodies to access or even discover what data is available where. It also makes it difficult for all UK stakeholders (public and private) to exploit the synergies between these data sets.

Our preferred option would be for the commission to lead the way in establishing a common national mechanism for accessing geospatial data in which most if not all UK public sector organisations would be able to participate, adopting common standards, formats, interfaces, licences and data policies. This does not mean a common *physical* infrastructure: elements of the mechanism could still be hosted by different organisations, with focus on enabling interoperability and a common point and means of access for all UK stakeholders, public and private.

Q10: What areas of the underpinning geospatial infrastructure such as positioning technologies, including GPS and indoor positioning systems, and geodetic networks and frameworks to support them, should we be prioritising the development of, in order to support the emerging requirements for geospatial data?

We fully expect to see an increase in the number of geospatial applications that combine the use of Earth Observation and positioning technologies and exploit the synergies between them. For example, surveying applications that use GPS/GNSS technologies could be augmented with superior knowledge of the local terrain and 3D environment derived from Earth Observation.

Underpinning technologies to be prioritised should therefore include

- Access to high integrity / high precision GPS/GNSS sginals post Brexit;
- Alternatives to Satelite-based Augmentation Systems (SBAS) e.g. for areas where SBAS does not work well, and/or for improved resilience;
- Security (for anti-jamming & anti-spoofing);
- Plus information technology and big data analytics technologies already mentioned (see Q7)

Q11: What role should the private sector have in both the development and maintenance of the underpinning infrastructure and enhancing the UK's geospatial data assets?

We are strongly in favour of the UK public sector sourcing as much as possible of the development and maintenance of the underpinning infrastructure from the private sector, as long as there are checks and safeguards in place to ensure that this infrastructure is made accessible to all UK stakeholders on a fair and equitable basis. If the capability exists in the private sector, and is cost-effective and has adequate competition, then it does not make sense to duplicate this capability in the public sector.

Q12. Do you face challenges when working with geospatial data from across the public sector? If so, what are they and how could value be better released? Are there any technical remedies or standards that could be adopted to improve the interoperability of geospatial data? Please provide supporting evidence of what these remedies could help to accomplish.

SMEs and large organisations have real issues navigating and negotiating data access, even for publicly purchased or provided datasets. Even data.gov.uk lists many datasets that cannot be systematically accessed, and there is no geospatially aware discovery mechanism. Public and private organisations need to be required and/or incentivised to make data public where possible, via standardised and easily accessible routes.

Q13. How can the Geospatial Commission act as a more effective customer for geospatial data on behalf of the public sector?

See also our response to Q6. Essentially, this involves:

- Identifying current and future geospatial data requirements across all relevant government departments and agencies;
- Consolidating these and identifying areas of duplication or overlap, so that relevant geospatial data can be acquired once and used multiple times;
- Making the needs and requirements openly visible to industry, such that industry can plan its own investment and technology development to meet future public sector needs;
- Act as coordinating procurement agency on behalf of government, tendering for 'geospatial information as a service' with decent length contracts (e.g. 3-5 years) and associated operational service level and quality criteria;
- Ensure level playing field for large and small companies to respond to these procurements, and engage multiple providers to ensure quality, diversity and resilience of data supply.

This type of sophisticated approach would ensure value for money for UK government when procuring geospatial data/information services, whilst also encouraging UK industry to invest and ensure continuity of supply for future government needs.

Q14. Are there any additional geospatial datasets, from the other partner bodies or other sources, that the public sector would derive significant benefit from having access to, that might have novel and valuable use cases? What would that access look like?

There are potentially numerous. Examples include insurance claims, crime statistics, accidents (road, domestic, industrial), traffic, footfall, noise, air pollution, news feeds, social media, elevation data, information on public utilities/services, electoral and census data, public transport data feeds, etc. As this data is currently difficult to access and exploit, the potential applications and use cases have not even started to be explored. A specific challenge would be the significant commercial and privacy issues around some of these data sets – certain types of data would likely need to be aggregated and/or anonymised.

Q15: How can we best develop a single UK strategy, ensuring alignment between the individual strategies across the UK while still allowing for national variations?

The Geospatial Commission should focus on setting a high level vision and ambition for the UK as a whole to achieve and benefit from superiority in geospatial data and information management and exploitation. As stated already, this vision and ambition should clearly include Earth Observation data and resulting information products within its remit. If this is done well, the national, regional and local authorities across the UK will be able to ensure that their own individual strategies, despite variations, work towards delivering the overall vision.

As a starting point, the nations and regions could be mandated to adopt a minimum set of common approaches, standards, interfaces and policies set out by the Geospatial Commission, with each free to exceed them, while remaining compatible. From an industry perspective, it is essential to adopt a straightforward approach which does not introduce new barriers – the strategy should be like an over-arching framework that permits national, regional and city level adaptations.

The UKspace Earth Observation Committee would be pleased to help the Geospatial Commission in defining this national strategy, if this would be helpful.

Q16: How can we best ensure effective local authority coordination and sharing of best practise, using location data to better deliver public services?

The key challenges here are (a) the lack of a clear and consistent set of standards and mechanisms for local authorities and other public sector organisations in the UK to record and share information regarding their services, and (b) the lack of any clear (centrally driven) incentives for them to do so. Leadership from the Geospatial Commission in this area will help to promote openness and sharing across these organisations.

Measures that are likely to help include:

- Develop common standards for all local authorities to adopt;
- Provide training and upskilling/reskilling amongst local authority users;
- Provide access to low-cost geospatial software tools;
- Develop a national geospatial data access mechanism (as per Q9) that local authorities are able to access and contribute to;
- Develop national geospatial data quality benchmarks/standards
- Establish special interest groups for knowledge sharing
- Share information and best practice through conferences / working groups

Q17: As a result of this analysis, we are prioritising the exploration of possible initiatives in the high-value categories identified:

- **property and land**
- **infrastructure and construction**
- **mobility**
- **natural resources**
- **sales and marketing**

What are the existing or potential geospatial applications which could be scaled-up or developed in order to capture economic value? (We would particularly welcome responses from industry and other bodies engaged in these sectors.)

It is not clear why the Geospatial Commission has selected these 5 sectors specifically, as there are many others to consider, including financial services, healthcare, insurance, smart cities, climate & energy, maritime and border security, and many others. Each of these has several potential geospatial applications within them. The UKspace EOC would be pleased to organise and participate in a workshop, with stakeholders from across the industry, to explore these in more detail with the Geospatial Commission.

Q18: Are there any other areas that we should look at as a priority?

We would like to see the Geospatial Commission encourage development and adoption of applications using remote sensing and Earth Observation across UK government. As data analytics and applications that integrate satellite, drones, high altitude platforms and other data emerge and evolve, along with complementing big data technologies like artificial intelligence and machine learning, the Geospatial Commission should ensure that these vital capabilities (in which the UK has excellent heritage) are clearly adopted and exploited as part of the national geospatial strategy. Remote sensing has numerous applications across government in helping to deliver policy priorities and monitor effectiveness of these policies; and any services developed in the UK to meet national requirements are readily exploitable by industry in commercial export markets.

Q19: What are the main potential private and public sector innovations that will rely on the use of geospatial data to rollout, and are there corresponding regulatory challenges?

There are many potential public and private sector innovations that would be unleashed by better access to geospatial data, including many that haven't even been thought of yet. As with Q17, the most effective way to flesh these out may be through a workshop with industry stakeholders

Potential regulatory challenges include:

- regulation around the use of HAPS, drones, autonomous vehicles and other aerial or terrestrial platforms to collect geospatial data;
- privacy issues including confidentiality and security of geospatial data that may allow individuals to be identified;
- regulation around the launch and operations of UK-owned commercial satellite constellations

In the context of Brexit, the UK also needs to ensure that adequate support is given to export initiatives through high value campaigns, trade missions, and promotion of UK geospatial capability in the international arena.

Q20: How best can we make the UK's presence in the international geospatial world more visible?

For the UK to become a world leader it needs to foster development of scalable, operational propositions which industry can then exploit in international markets.

To enable this, the UK urgently requires a joined-up national approach to collecting, storing, sharing, disseminating and exploiting global geospatial data sets, which brings together UK stakeholders from across industry, research, academia and government working together towards a common goal.

The Geospatial Commission is uniquely placed and funded to make this happen, working closely with the other key initiatives, notably the UK Space Agency's efforts to provide operational EO data access for the UK, the UK Space Sector Deal, the ISCF Wave 3 "Space Data Revolution" proposal, and the export initiatives of the Department for International Trade. With Geospatial Commission leadership and coordination, the UK can create a highly visible showcase for British technology and capability worldwide, highlighting its reputation for delivery of trusted, high-integrity geospatial data and resulting information products.

Once we have a coherent national approach, UK capability and services will speak for themselves in the international geospatial world. There are also several international fora where the Geospatial Commission can actively promote UK capability – for example CEOS, UN-GGIM, GEO or the International Charter for Space and Natural Disasters – working closely with UKSA, Defra and other relevant UK bodies.

Q21: Where should the UK be looking for points of comparison overseas? Who are the other international exemplars? What best practice is being modelled overseas that we can learn from?

The European Copernicus DIAS platforms are rapidly becoming centres of gravity for hosting EO and complementary non-EO geospatial data in Europe, along with relevant tools, storage and processing capacity to exploit the data, and with e-Commerce facilities to enable commercial applications to be built and served.

Australia has invested significantly in its open data cube implementation, which has now been embraced by CEOS. Some states like Queensland are routinely procuring state-wide high resolution coverage on an annual basis and making it available to its public services.

France and Germany have invested significantly in national EO data centres (PEPS and CODE-DE respectively). The Netherlands is routinely purchasing satellite data coverages of the country, as well as collecting Sentinel 1 and 2 data, and making raw and pre-processed ARD freely and openly accessible to Dutch users from government and industry.

In terms of geospatial big data implementation, North America is leading the way. The USA has established a national geospatial platform (www.geoplatform.gov) and Canada is establishing its own Federal Geospatial Platform. In the private sector, North American organisations such as Amazon, Google, Planet, Maxar/DigitalGlobe, BlackSky, Urthecast and others are investing heavily in this

domain, recognising the commercial potential.

Thank you for your time in completing your response to our call for evidence.

Any questions, please get in touch with the Geospatial Commission via geospatialcommission@cabinetoffice.gov.uk

Geospatial Commission: Call For Evidence Response Questionnaire

Please submit your completed questionnaire to:

geospatialcommission@cabinetoffice.gov.uk.

Clearly title your email *'Call for evidence response'*.

About you and your organisation

Small business (10 to 49)	
Micro business (up to 9)	
Other - please state	**Academic institution**

Background Information on Respondents

This response to the call for evidence is a consolidated one from the University of Edinburgh and comprises input from EDINA and the School of Geosciences. For information a little background to each is provided.

EDINA @ University of Edinburgh

EDINA is a world-class centre for digital expertise, developing unique technology solutions for the UK academic and public sectors as well as external clients. Operating as a stand-alone business unit, based in the University of Edinburgh, EDINA has circa 40 staff, comprising software developers, project managers, service support and business development, and has a £3m annual turnover. EDINA has an 'intrapreneurial' role within the University of Edinburgh working in collaboration with all three Colleges, as well as established external partnerships in the private sector and with funders (such as ESRC) across the UK and internationally.

In existence for over 20 years, EDINA runs (*inter alia*) an established geospatial data and mapping platform (Digimap - digimap.edina.ac.uk) providing subscription based services for the UK education sector, which it delivers to 130 Higher Education Institutions, 360 Colleges and 3000 schools and is in daily use by around 65,000 users. EDINA has developed and supported theses services (including running a bespoke Helpdesk servicing around 5000 annual support queries), and provides extensive online learning and training resources.

Digimap offers a range of online web based clients to create customised maps and to perform custom data extraction operations against a wide range of large commercially valuable geospatial data collections that currently include:

- **OS Digimap** - access to large scale Ordnance Survey® data.
- **Historic Digimap** - historic maps from Landmark Information Group.
- **Geology Digimap** - geological maps and data from the British Geological Survey.
- **Marine Digimap** - hydrographic maps and data from (at writing) SeaZone Solutions.
- **Environment Digimap** - Land Cover Maps and data from the Centre for Ecology & Hydrology (CEH).
- **Aerial Digimap** - high resolution Aerial Imagery data from Getmapping Plc.
- **Lidar Digimap** - high resolution Lidar data from national UK agencies.
- **Global Digimap** - access to Open Street Map and Natural Earth data collections.

Geosciences @ University of Edinburgh

The School of Geociences at University of Edinburgh is the largest and most successful interdisciplinary grouping of geoscientists and geographers in the UK, with a growing and cosmopolitan academic and research staff of more than 300 academic and research staff; more than 100 non-academic staff; around 470 postgraduates (half of whom are on taught masters courses), and over 1,100 undergraduates.

The School was formed in 2002 through the merger of the former Institute of Ecology and Resource Management, the Department of Geography, the Department of Geology and Geophysics, the Institute for Meteorology and Environmental Chemistry from the Department of Chemistry - all of which have had a long history within the university, dating back to the eighteenth and nineteenth century, and influenced by an impressive selection of scientists and social scientists who have shaped the School's core disciplines (ecology, environmental sciences, geography, geology, geophysics, meteorology, oceanography) and areas of expertise.

Our questions

Q1. Is our view of the geospatial data types accurate? If not, what should be included or excluded from this?

Broadly yes though we would distinguish between core framework GI data and ancillary positional/location data in which the geography component is often of secondary importance. Spatial data as a type is important and while we should resist adopting a 'spatial is special' epithet, the importance of place and a geography to link other datasets together cannot be underestimated.

It is of concern that partner agencies do not include the fields of transport, the environment, health and their associated datasets, together with earth observation (EO) data. We would encourage the broadest possible definition of spatial data.

We would expect to see some reference to attribute data – not as a specific geospatial data type but at least recognition that it is a combination of geospatial reference data with attribute data that then enables analysis/modelling.

Q2. In addition to current government policy, what are the areas of geospatial skills where the commission could best focus, to help ensure the necessary capability within the UK for the future?

The University of Edinburgh is a leading provider of education and training in geospatial, with some of the world's longest established Masters programmes in GIS and EO, together with training of researchers and professionals, and provision of geospatial skills to schools. Our community (the Higher and Further Education aka Higher Education Institutions (HEIs) and Schools sectors) are already a heavy GI consumer through sectoral licensing agreements and a range of services that we provide. Our users are often subject experts but their use of geospatial data requires them to acquire and develop additional skills in geospatial data handling. Critically, the geospatial communities we serve are cross domain and cross disciplinary. Spatial data is not just used by geographers but is used across all disciplines.

However, as acknowledged nearly a decade ago [https://www.ratswd.de/download/RatSWD_WP_2009/RatSWD_WP_88.pdf] there are significant skills gaps and lack of coherence in both skills delivery and appreciation of the geospatial tooling and infrastructure already available. Spatial literacy is frequently under appreciated yet permeates most day-to-day activities in a digital society (from simple route navigation and map reading to sophisticated spatial analyses for service planning and delivery). In that respect the trend in the erosion of geography as a core subject area in schools whilst the increasing employability of geography graduates provides a mixed picture in terms of geospatial skills development. Geographical skills are more relevant today than ever before and an appreciation of spatial/GI should be a core ambition of the Commission - not just to geospatial professionals but to lay GI users across all

sectors.

The commission should thus focus upon curriculum setters/examination boards across all nations to introduce spatial literacy explicitly into the curriculum. The commission should emphasise how critical spatial literacy skills can be to developing critical thinking and data handling skills in pupils, especially when presented with geospatial data/themes for their local areas. This is not about getting GIS into schools per se - it is about developing spatial literacy and geospatial competencies to ensure students have the skills required that will be increasingly in demand in a growing employment sector.

While there is relatively good degree-level education, providing a steady supply of GI professionals, it is not clear that this provision will meet growing and future demand.

At technician level, provision is poor. Despite the existence of Scottish Qualifications Authority mandated qualifications, few FEIs offer these and the uptake by students these has been virtually non-existent. There is little or no precedent for apprenticeships within the industry, and companies do little to promote GI/EO as a career beyond their own walls. Expertise among teachers within the discipline of school geography is low, and again there is little recognition of GI/EO as a career pathway. The Commission should urgently address these issues, perhaps by encouraging partnerships across geography, a broader environmental curriculum and ICT.

In general, the advent of increasing amounts of EO and sensor data (IoT) suggest that a deficit in skills in these areas could stifle adoption. Similarly, and not unrelated, the skills required for advanced interpretation of GI using AI/ML approaches is another area where there will likely be a critical shortfall of appropriately skilled personnel. The Commission should consider urgently plans on how to address this - possibly through encouraging Data Apprenticeships and journeyman routes such as being pioneered by e.g. ONS Data Campus, including ONS's collaboration with EDINA at the University of Edinburgh, to leverage and grow a cross curricula, geospatial service that is already being delivered into 3000 schools UK wide.

Q3. What are the geospatial skills needs and gaps in your organisations, how can these be most effectively addressed, and how can careers in the sector be best promoted?

As previously mentioned, the range of skills required is broad as is the potential audience to whom such skills are relevant. Organizations (HEIs) tend to address these pragmatically but in an uncoordinated and piecemeal fashion. A core GI Body Of Knowledge should be promulgated and adequate formal and informal qualifications and accreditation courses be rationalized in an effort to instill a sense of pride in a profession that is frequently underplayed - as attested by careers routes for new graduates, CPD routes and general recognition. The Commission should liaise closely with bodies such as AGI, GA, RGS, RSGS, IBG, RICS, BCS to rationalize and standardize the GI skills landscape. Variety is both a strength and a weakness - at minimum better signposting and options summaries for aspiring career professionals would assist.

Q4. Are there any publicly or privately-held geospatial datasets that are currently challenging to access or use or of insufficient quality, but which you or your organisation would find valuable if these issues could be resolved? Please explain why this would be of value, and how access/quality could be improved?

While recent developments including the INSPIRE regulations have encouraged a culture of making more data available, there is still much to be done. Complex access procedures (and cost) remain barriers to effective research. All parties need to do more to provide web mapping services (WMS and WFS) which can provide data in real-time from host organisations. Consistency of provision and access is to be encouraged; data.gov.uk lacks organisation and structure.

There is concern that the Commission does not have partnerships with the likes of the Highways Agency, Environment Agency, Met Office, Historic England and many others who are important producers of geospatial information. There is particular concern that the Commission is not partnered with the Scottish equivalents of these agencies, and also the Scottish equivalents of HMLR (the Registers for Scotland) and the Valuations Agency (Scottish Assessors). The Commission needs to address this shortcoming in a formal manner, otherwise an important part of the UK will potentially miss out on Commission-led developments.

The UK higher education community has long wanted access to detailed addressing and postcode products but residual and confusing IPR have meant that this is problematic and has acted as an impediment to research. Removing or at least simplifying routes to access fro this information for teaching and research purposes would add substantial value to UK GI research. To a lesser degree other data sets such as a timely and consistent view of UK land use data would be valuable for research. The UK academic sector has (for many years) benefited from licensed access to OSMM and other ‘core’ GI datasets such as BGS data although specific datasets such as e.g. the radon dataset remain problematic to access. Some of this is due to cost, some to 3rd party residual IPR and some due to a general lack of awareness of whats available. Even where open data are available it is not always readily apparent where and how to access or even that

data exist. Whilst data.gov.uk solves some of this there is still too much fragmentation in providing a coherent, consistent and canonical view of what data are available under what conditions. EDINA have long promoted interoperability through standardised metadata (and are heavily involved in UK GEMINI) but wide-scale adoption and promotion (AGI efforts notwithstanding) remains illusive (both within and without academia). Services, tools and education to address the 'know what we have' problem remains as much needed today as it did at the time of GIGateway and its successors.

Q5: Do you anticipate that any changes will be needed to the both address data and the wider address ecosystem, to support emerging technologies? Please provide evidence of value to support any proposed changes.

We note and welcome the opening up of key parts of Ordnance Survey's Mastermap product family such as property extents and TOIDs However,these do not provide the essential link between everyday addressing and the digital geospatial infrastructure. Addresses matter because, regardless of the locational referencing standards adopted by government and geospatial technology companies, textual addresses remain the most universally used form of locational information among the general population. Addresses are the locations at which most journeys begin and end, the descriptors of properties that are bought and sold, the spatial positions which qualify individuals to access services and receive benefits. It is therefore textual address information held within the National Address Gazetteer and not the TOID or spatial coordinates which provides the only linkage field for many key datasets, ranging across NHS registration, social survey data and many other customer and government databases. The continuing lack of an open register linking addresses to definitive identifiers obstructs data linkage, research and innovation at many levels and produces inconsistent results when alternative approximations are used.

The case for an open address register has received extensive attention e.g. by the Open Data Institute and government-commissioned reviews, for example the Independent report for government on the feasibility of an open address gazetteer https://www.gov.uk/government/publications/an-open-national-address-gazetteer whose recommendation was "that a basic address product should be free to all users at the point of use under the Open Government Licence". This continues to be a priority if the value of geospatial information is to be fully realised.

Vast amounts of spatial data are now being contributed by volunteers through smartphone apps and other non-traditional means; the Commission should address issues of accessibility of these new forms of data.

Q6: How should the commission be looking to develop the UK's capability in Earth observation data, both technologically and to support an effective market?

As noted earlier, the main threat to the UKs ability to best exploit the explosion in EO data and its potential applications is one of data skills and the currently rarefied skill matrix required to intersect both EO interpretation with machine intelligence. EO + AI could revolutionize GI data exploitation and its real world application to large societal challenges yet the numbers of the work force with the skills required to avail of this are negligible. Whilst not unique in as much that data science skills are generally at a premium, the additional GI specific challenge afforded by EO means that the UK market (public and private) is ill placed to swiftly capitalize upon the 'space data revolution'. A curricula of industry relevant core skills allied with their educational provision is urgently required.

Q7. Which new technologies should the commission focus on to provide new opportunities to process and exploit geospatial data for economic growth?

Emerging - EO + AI; IoT; Wearables;autonomous vehicles; location smart contracts;

Established (variable maturity) UAVs, BIM, 3D, AR/VR; Indoor location

Q8. How can geospatial data and applications be used to support enhanced roll-out of future technologies?

Geography and therefore the use of spatial data is both ubiquitous and often unexpected. Using outdoor and indoor location methods, web location and suchlike, recording location has become easy and will be embedded in new applications. Understanding how this data can and should be used will become crucial as applications move into non-traditional fields.

There may be issues of data protection and personal security which the Commission needs to address in conjunction with the Information Commissioner(s).

Q9: What are the options for how public sector organisations could continue to invest in maintaining and enhancing our geospatial data assets?

The various options for a ‘solution’ to this have been exhaustively explored over a number of years - from making data completely open in the hope of generating private sector innovation, to cross-subsidy models that generally involve pay-for-use. The core issue we believe is negotiating a balance between public good and private profit. We suggest a more collaborative public:private model where both ‘sides’ can exchange value (not necessarily in solely monetary terms but also in terms of knowledge exchange, best practice and skill development). Where chargings need to remain an important part of the business model of organisations such as Ordnance Survey and the Hydrographic Office, we encourage a link between cost and value; where those organisations making significant financial gain from the data contribute to its costs of maintenance and collection, whereas small businesses, those operating in a personal capacity, teaching and research should benefit from free availability.

Q10: What areas of the underpinning geospatial infrastructure such as positioning technologies, including GPS and indoor positioning systems, and geodetic networks and frameworks to support them, should we be prioritising the development of, in order to support the emerging requirements for geospatial data?

GPS (assuming no Galileo access post-Brexit), indoor positioning and general geodetic revision to avail of new more precise positioning technologies.

Certain core geographies should be freely available; including addresses and an extensive placename gazetteer. These are crucial in terms of creating linked data.

Q11: What role should the private sector have in both the development and maintenance of the underpinning infrastructure and enhancing the UK’s geospatial data assets?

A key role although set within the Vision owned and driven by the Commission on behalf of UK taxpayers.

It is important that the Commission engages with the private (and third) sectors in terms of data availability and to simplify the arrangements where data is being used for research purposes in conjunction with commercial organisations.

The Commission should encourage mutually beneficial public-private partnerships to ensure, for example, popular web mapping offerings are enriched, but equally that resurvey and maintenance costs are shared. It is ultimately in the public good that effort is shared.

Q12. Do you face challenges when working with geospatial data from across the public sector? If so, what are they and how could value be better released? Are there any technical remedies or standards that could be adopted to improve the interoperability of geospatial data? Please provide supporting evidence of what these remedies could help to accomplish.

As previously noted, major challenges including knowing what geospatial data exist and having them available in an easily consumable form (WMS/WFS) remain issues. Adopting common metadata standards to describe extant data holdings provides one remedy. Even where data are discoverable and their fitness for purposes can be assessed, often the data format or data volumes may prove challenging. The geospatial interoperability standards promoted by both OGC and enacted via INSPIRE in the public sector are partial solutions. However, many of the technocratic solutions are arguably too complex and can themselves act as barriers to adoption. A policy that adopts a principle of 'only as complex as the solution demands' needs to be pioneered which would allow for a richer ecosystem of geospatial services at varying degrees of technical complexity whilst observing the essential precept - build once, use many times. Many users only want GI data to solve a problem, not as an end in itself and therefore the GI component may be better viewed as an invisible enabler - this is likely even more true for EO applications where size and complexity become even more obvious. More prosaically, much geospatial data is administrative in nature, and there remain major challenges of data access and consistency across government. A major step forward would be achieved if e.g. validated standard addresses were used more consistently at the point of entry across government organizations, including NHS and DWP/HMRC so that high quality information on households and services is consistently generated and therefore more readily linked and georeferenced. This would greatly facilitate administrative data research (which in UK HE has been the subject of substantial research council funding) and would also be supportive of the government's declared intention to move towards an administratively-based census after 2021. Standards already exist to enable much of this work and much has already been accomplished. There is however much more to do.

Data.gov.uk is barely fit for purpose.

Q13. How can the Geospatial Commission act as a more effective customer for geospatial data on behalf of the public sector?

The UK academic sector is currently not covered either by the existing Public Sector Mapping Agreement (or the Scottish equivalent) with the result that there is no national academic access mechanism for definitive datasets such as PAF . This impedes not only the ability to help meet identified needs for geospatial skills training but also leads to unnecessary expenditure of public funding - for example through UKRI and UK research councils' funding being used to repeatedly purchase small extracts from products for defined projects. Wrapping these products into existing national licensing agreements to the academic sector could help reduce overall expense and assist rather than frustrate primary research.

At a general level we would question the existence of a data marketplace within the public and third sectors - at least one that is principally compelled by economics over social good.

Q14. Are there any additional geospatial datasets, from the other partner bodies or other sources, that the public sector would derive significant benefit from having access to, that might have novel and valuable use cases? What would that access look like?

We have noted following above but repeat here for emphasis. There is concern that the Commission does not have partnerships with the likes of the Highways Agency, Environment Agency, Met Office, Historic England and many others who are important producers of geospatial information. There is particular concern that the Commission is not partnered with the Scottish equivalents of these agencies, and also the Scottish equivalents of HMLR (the Registers for Scotland) and the Valuations Agency (Scottish Assessors). The Commission needs to address this shortcoming in a formal manner, otherwise an important part of the UK will miss out on Commission-led developments.

Much government administrative data is either implicitly or explicitly geospatial in nature yet remains siloed or unobtainable (often even to other government

departments). Establishing a canonical catalogue of such data allied with the adoption of clear (and simply worded) data sharing agreements could greatly assist in better exploitation of valuable GI assets. Accepting that many such datasets may contain confidential or disclosive information, the Commission should consider how modern data linkage techniques (using anonymity preserving one-way data hashing algorithms) could free up 'sensitive geospatial data'. This may also unleash serendipitous data associations as the full value of data fusion is finally realised.

Q15: How can we best ensure effective local authority coordination and sharing of best practise, using location data to better deliver public services?

The ubiquitous nature of geography, and therefore geographical information, means it remains a challenge to define a user community. The Commission should use existing networks, and encourage the development of new ones, to share best practice and deliver better public services.

Sections of academia already work closely with local authorities via e.g. the Business and Local Government Data Research Centre; the Urban Big Data Centre; the UK Data Service. Formalising these relationships via e.g. a Commission-sponsored Local Government and Academia Network would mutually assist both local government and researchers. A single recognized fora would make it easier for experts on both sides of the divide to exchange and share best practices. The separation between academic research and local government practise is often a question of ensuring that both sides can successfully meet. Commission supported networking events (possibly enacted through or mediated by AGI) could assist.

Q16: As a result of this analysis, we are prioritising the exploration of possible initiatives in the high-value categories identified:

- **property and land**
- **infrastructure and construction**
- **mobility**
- **natural resources**
- **sales and marketing**

What are the existing or potential geospatial applications which could be scaled-up or developed in order to capture economic value? (We would particularly welcome responses from industry and other bodies engaged in these sectors.)

UK academia has significant interest across all of the above sectors so its is hard to chose just a single category. One additional significant area of research is health and population studies - especially those relating to greenspace and health. We would agree re health data and would provide comment that we are surprised on emphasis within the paper upon physical features – topographic, marine and geological as opposed to 'human' socio-economic data incl health, wealth distribution, life expectancy etc. Arguably these are attributes of geospatial data hence reference to response to question 1.

Just as location-based services have developed for the smartphone, there will be new categories which will develop in coming years in a fast-moving field. The availability of richer EO data and new technologies such as the IoT will bring applications as yet unimagined, across the above and many other sectors.

Q17: Are there any other areas that we should look at as a priority?

Address and Postcode data
Population and migration data.
Landcover data
Interaction and flow data (people, goods, services)
High value environmental data e.g. high resolution LiDAR/ Green LiDAR
Sensor network feeds from Smart City initiatives
Commercial data from private sector such as geodemographics data
Utilities geospatial data
Network/4g/5g data

Q18: What are the main potential private and public sector innovations that will rely on the use of geospatial data to rollout, and are there corresponding regulatory challenges?

EO data, UAV data and IoT devices all have the potential to vastly increase the availability and application of GI in the UK but each poses its own regulatory challenges relating most significantly to privacy and safety. UAVs (and autonomous vehicles more broadly) given their mass market appeal and their potential nuisance and safety risks pose particular challenges for adoption.

Q19: How best can we make the UK's presence in the international geospatial world more visible?

By leading by example and better showcasing UK talent - much of which emanates from UK education institutions and private industry. International exchanges, trade shows and knowledge exchange partnerships can all help but better exploitation of GI in the home market will, in and of itself, underline the UK's interest in and mastery of GI data and technologies. Success on the domestic front will draw International interest.

The UK's international profile is currently limited to the residual role of their former Overseas Survey, vested in OS (OSI).

The UK does not take any significant role in the way of the NGDC and USGS in the USA, which take responsibility for collating and being the source of international databases (eg. DEMs, earthquakes). Where could the UK lead, could the UKHO make available historical ocean data? There are opportunities in terms of new EO data collected by the UK.

We can capitalise on this through offering an international marketplace for our expertise.

Q20: Where should the UK be looking for points of comparison overseas? Who are the other international exemplars? What best practice is being modelled overseas that we can learn from?

Australia (CSIRO) ,NZ (Landcare), US (NGA), EU (Eurogeographics) as well as OGC Europe. However no single country has a monopoly in all the areas geospatial covers and therefore one would need to isolate best practice in any given domain. .Many of the existing European Mapping and Cadastral Agencies have initiatives and experiences that UK could better make use of through engagement with e.g. EuroSDR and AGILE

Thank you for your time in completing your response to our call for evidence.

Any questions, please get in touch with the Geospatial Commission via geospatialcommission@cabinetoffice.gov.uk

Geospatial Commission: Call For Evidence Response Questionnaire

Please submit your completed questionnaire to:

geospatialcommission@cabinetoffice.gov.uk.

Clearly title your email *'Call for evidence response'*.

About you and your organisation

Name	[Text redacted]
Organisation	Individual, University of Leicester
Job title	[Text redacted]
Address	[Text redacted]
E-mail	[Text redacted]
Telephone	[Text redacted]

Please select which of the following best describes you as a respondent:

Respondent	**Please mark with a X**
Academic	**X**
Business representative / trade body	
Central government	
Charity or social enterprise	
Individual	
Legal representative	
Local government	
Large business (over 250 staff)	
Medium business (50 to 250)	
Small business (10 to 49)	
Micro business (up to 9)	

Other - please state	

Call for evidence - three key themes

We have identified three high-level themes that could help our approach to setting a strategy which are as follows:

1. **Supporting innovation in the geospatial sector**, exploring how to secure cutting edge skills, the right access to data, and opportunities from emerging technologies for the geospatial sector itself
2. **Enhancing the UK's geospatial assets,** looking at how best to align interests, avoid duplication, and instill best practice across the whole public sector
3. **Driving investment and productivity in geospatial applications**, asking in which wider sectors the most value lies from better exploitation and use of geospatial data, in the UK and internationally

Our questions

Q1. Is our view of the geospatial data types accurate? If not, what should be included or excluded from this?

It is not entirely accurate. Geospatial data generally fall into two categories: raster and vector data. Data for which place is a key feature of its source and purpose is generally called geographic data.
Data is not the same as information, either. These terms should not be used interchangeably.
Geospatial data should also be differenciated from georeferenced data.

Q2. In addition to current government policy, what are the areas of geospatial skills where the commission could best focus, to help ensure the necessary capability within the UK for the future?

Additional areas where the UK needs skills for the future include satellite remote sensing, cloud computing, data analytics and programming, especially Python, integration of information from multiple data platforms to quality control and support interpretation of information from EO. These could include surface observations and models of varying types and complexities (e.g. box models and detailed Earth System Models).

Q3. What are the geospatial skills needs and gaps in your organisations, how can these be most effectively addressed, and how can careers in the sector be best promoted?

The University of Leicester needs highly skilled researchers with experience in radar, LiDAR and multispectral remote sensing, cloud computing, data analytics and programming, especially Python and R. General Earth system science skills and an understanding of the climate system are also needed.
These skills requirements can be most effectively addressed through postgraduate taught courses at MSc level and postgraduate research programmes (PhD and MPhil), complemented by continuous professional development (CPD) events for existing research staff.
Demand for these skills is higher than supply. This deficit could be addressed by injecting increased funding into training the next generation of geospatial experts. This would ideally take the form of MSc and PhD scholarships in a research group with a focus on downstream applications of Earth Observation (EO). The student experience would be enhanced by a short-term placement at an EO company after sufficient training has taken place.

PhD training is more effective than short-term or online courses for building the foundation of specialised skills in data use, analysis and interpretation. After that, short-term and online courses offer a useful mechanism for keeping pace with new developments and techology/tool updates.

Q4. Are there any publicly or privately-held geospatial datasets that are currently challenging to access or use or of insufficient quality, but which you or your organisation would find valuable if these issues could be resolved? Please explain why this would be of value, and how access/quality could be improved?

The UK national land cover maps at the Centre for Ecology and Hydrology (CEH) are prohibitively expensive.
The Countryside Survey data at CEH would be valuable, but are inaccessible.
Anonymise data on crop types and land use from the Rural Payments Agency would also be valuable.
All these datasets would be valuable as training and validation datasets for non-profit research.

Q5: Do you anticipate that any changes will be needed to the both address data and the wider address ecosystem, to support emerging technologies? Please provide evidence of value to support any proposed changes.

We are not providing a response to this question.

Q6: How should the commission be looking to develop the UK's capability in Earth observation data, both technologically and to support an effective market?

The UK needs to secure continuity of involvement in the European Copernicus Programme to retain access of UK industry and academia to tenders and contracts for developing the next generation of Copernicus, as these data will drive future growth in the downstream market. Continued access to Horizon 2020 and future research framework programmes are very important for universities to maintain our international collaborations with Europe.
Free and open access and data continuity with a longevity of operational missions, following the Copernicus model, are important to develop the UK's capability.
Access to high performance and cloud computing services for developing prototype EO applications before they go to market are valuable, e.g. CEDA / CEMS.
Observations of air pollutants at higher spatial resolution than is achieved with the current instruments in space. The current fleet provide valuable information about long-term changes in air quality over wide domains (~7-20 km), but the resolution isn't high enough to identufy partiuclar polluters, to link pollution to exposure and

negative health effects, and assess the efficacy of clean air zones. The value is substiantial improve air quality tools to effectively develop policies that mitigate premature deaths (40,000 per year in the UK), crippling fines for infringements (more than £100 million per year to the UK), and and estimated £20 billion per year in health care costs.

Q7. Which new technologies should the commission focus on to provide new opportunities to process and exploit geospatial data for economic growth?

Key development areas in Earth observation include hyperspectral Earth observation, multi-wavelength LiDAR and free and open data from L-band Synthetic Aperture Radar (SAR).
Augmented reality and virtual reality as a device to communicate and visualise the information these datasets provide.

Q8. How can geospatial data and applications be used to support enhanced roll-out of future technologies?

Enhanced roll-out can be achieved through platforms allowing free and open access to demonstration datasets and services. Standardised data streams and user portals would be helpful.
Maintaining compliance with the INSPIRE Directive is strongly advisable.

Q9: What are the options for how public sector organisations could continue to invest in maintaining and enhancing our geospatial data assets?

Public sector organisations need to provide secure long-term investment in framework contracts for collecting environmental and other geospatial data in order to monitor changes. Such contracts would best go to organisations with monitoring and data provision remits such as the Natural Environmental Research Council's centres and surveys (BGS, CEH etc.) and Defra.

Q10: What areas of the underpinning geospatial infrastructure such as positioning technologies, including GPS and indoor positioning systems, and geodetic networks and frameworks to support them, should we be prioritising the development of, in order to support the emerging requirements for geospatial data?

Continuity of involvement in GNSS and continued innovation of its locational accuracy are important.
Rapid data access through upgraded internet bandwidth in all regions of the UK is required to get geospatial data to all possible users.

Q11: What role should the private sector have in both the development and maintenance of the underpinning infrastructure and enhancing the UK's geospatial data assets?

The role of the private sector is threefold:

1. Innovation of Earth observation hardware (future satellite instruments and technology etc.), geospatial infrastructures, algorithms and data portals through collaborative activities with academia
2. Delivery of cost-efficient infrastructure to enable data access
3. Contracted service provider to add value to datasets and turn data into information

Q12. Do you face challenges when working with geospatial data from across the public sector? If so, what are they and how could value be better released? Are there any technical remedies or standards that could be adopted to

improve the interoperability of geospatial data? Please provide supporting evidence of what these remedies could help to accomplish.

Challenges that we have faced include overcharging for geospatial data even though their production was paid for from public funds (e.g. UK land cover map by CEH), lack of access with reference to confidentiality (e.g. Rural Payments Agency, Defra Countryside Survey) and difficulties finding the dataset we were looking for but did not know existed. Datasets are held by a myriad of departments, centres and agencies, and for lay people it is almost impossible to find what they are looking for.
A central data catalogue of all public datasets would be very helpful, in accordance with the GEO principles.
For datasets subject to some degree of confidentiality, a suitably anonymised form of the data should be made available.

Q13. How can the Geospatial Commission act as a more effective customer for geospatial data on behalf of the public sector?

The Commission can provide focus and support a one-stop data catalogue for all public geospatial datasets. This could be coordinated with the GEO Data Portal.

Q14. Are there any additional geospatial datasets, from the other partner bodies or other sources, that the public sector would derive significant benefit from having access to, that might have novel and valuable use cases? What would that access look like?

We are not providing a response to this question.

Q15: How can we best ensure effective local authority coordination and sharing of best practise, using location data to better deliver public services?

Shared geospatial service centres are an effective way of supporting multiple local authorities in accessing data.

Q16: As a result of this analysis, we are prioritising the exploration of possible initiatives in the high-value categories identified:

- **property and land**
- **infrastructure and construction**
- **mobility**
- **natural resources**
- **sales and marketing**

What are the existing or potential geospatial applications which could be scaled-up or developed in order to capture economic value? (We would particularly welcome responses from industry and other bodies engaged in these sectors.)

Natural Capital valuation and ecosystem services valuation can underpin Payment for Ecosystem Services Schemes (PES).

Q17: Are there any other areas that we should look at as a priority?

We are not providing a response to this question.

Q18: What are the main potential private and public sector innovations that will rely on the use of geospatial data to rollout, and are there corresponding regulatory challenges?

Space-based data for climate and models: Space-based geospatial data are increasingly used for climate research and for providing independent evidence of the magnitude and impacts of climate change. New analysis methods for geospatial climate data records to advance the understanding of global climate change and research enabling the collection of new climate observations are needed to advance knowledge in this field. Development of an easy-to-use climate data assimilation tool into models would be an exciting innovation that would enable more researchers to use these techniques. Joining land surface and atmosphere models, e.g. JULES and GEOS-CHEM, would allow new advances in knowledge of land/climate feedbacks. UK leadership of major initiatives such as the ESA climate change initiative, the Copernicus Climate Service and the Copernicus Land Monitoring Service prove our track record.

Urban environments and human health: Air quality and urban heat islands have detrimental impacts on human health. Urban green spaces can mitigate these pressures, which still present a major environmental challenge to the UK and many other countries around the world. Earth observaitons of atmospheric composition to monitor air quality at high enough spatial resolution to assess the impact on health and the terrestrial biosphere are needed.

EO data science: The EO data revolution is leading to rapidly growing amounts of available space data which create challenges to the development of new downstream applications. New satellite missions generate ~1Tb of data per day with a wide range of applications for cities, agriculture, air quality, biodiversity, flooding etc. Advanced retrieval techniques as well as cloud computing and big data analytics, such as machine learning and artificial intelligence, are needed to realise the full potential of contemporary space infrastructure and the data it generates. Smartphone apps can contribute to democratising EO data access.

EO for sustainable development: Geospatial data support and enable the pursuit of the United Nations Sustainable Development Goals, which aim to solve some of today's most pressing development problems, including the rapid loss of tropical forests, availability of sufficient amounts of clean water and unsustainable land use change, as well as air quality, climate risks to food security and agriculture.

EO instrumentation and missions: UK researchers have strong links to European and international satellite missions. The research field of development of instrumentation and new missions is an area with continued, strong investment by UKSA and ESA. UKSA has growing interest in both national and in bilateral missions in addition to the UK investment into ESA. Opportunities exist especially in airborne demonstrators and in instrument bread boarding in key technologies supported by the UKSA CEOI programme.

Q19: How best can we make the UK's presence in the international geospatial world more visible?

Programmes such as the UKSA International Partnership Programme (IPP) are a great way for UK industry to access international markets.
Increased engagement with the Group on Earth Observations (GEO) and the Committee for Earth Observation Satellites (CEOS) will make the UK's presence more visible. Programmes such as IPP should review which activities can be badged as GEO.

Q20: Where should the UK be looking for points of comparison overseas? Who are the other international exemplars? What best practice is being modelled overseas that we can learn from?

More funding opportunities that promote collaboration with international researchers and policymakers and exchange of best practice ideas.

Thank you for your time in completing your response to our call for evidence.

Any questions, please get in touch with the Geospatial Commission via geospatialcommission@cabinetoffice.gov.uk

Call for evidence - three key themes

We have identified three high-level themes that could help our approach to setting a strategy which are as follows:

1. **Supporting innovation in the geospatial sector**, exploring how to secure cutting edge skills, the right access to data, and opportunities from emerging technologies for the geospatial sector itself
2. **Enhancing the UK's geospatial assets,** looking at how best to align interests, avoid duplication, and instill best practice across the whole public sector
3. **Driving investment and productivity in geospatial applications**, asking in which wider sectors the most value lies from better exploitation and use of geospatial data, in the UK and internationally

Our questions

Q1. Is our view of the geospatial data types accurate? If not, what should be included or excluded from this?

- **Data v information**

The classes of use would seem about right. However, the descriptors mix both 'data' and 'information'. Data is more fundamental/foundational and an argument could be made that it is the role of geospatial analytics/GIS/geocomputation etc to unlock the information from the data. Primarily, the subject of information in the 'call for evidence' is about *data*. The important link to *information* needs to be emphasised, however this is distinct.

Q2. In addition to current government policy, what are the areas of geospatial skills where the commission could best focus, to help ensure the necessary capability within the UK for the future?

- **Spatial literacy**

To further the work being done in the UK and US to embed spatial skills and spatial literacy concepts across diverse curricula at secondary and tertiary levels of education.

- **Spatial data science**

At present new developments in Higher Education (HE) in the US (usually a good weather vane of disciplinary trends) is very much in two areas: (1) *Spatial Data Science* and how this can complement existing geospatial skills in GIS and EO programmes (2) *professional science masters* providing business skills alongside geospatial skills.

- **Reproducibility**

As many other quantitative sciences, there is an urgent need for assure the reproducibility of research results, in academia as well as in the business and policy sector. This is crucial to promote reliability and transparency. At the moment there is a lack of both practice and teaching of reproducibility approaches in GIScience.

Q3. What are the geospatial skills needs and gaps in your organisations, how can these be most effectively addressed, and how can careers in the sector be best promoted?

- **Science and applications**

Geospatial skills needs encompass both experts/expertise in the science behind GIS/geospatial skills (i.e., GIScience) and in their downstream application of the technology (e.g. using GIS). There is a general lack of GIS expertise with high-level programming/ database skills to meet the demands of processing/analysing data in the academic sector. It is consequently very difficult to obtain and retain staff.

- **Stakeholders**

The first obstacle to the effective support of geospatial careers wither reference to GIS has historically been the multiplicity of stakeholders (AGI, RGS-IBG, JISC, RICS etc) in the public and private sectors. Hopefully the geospatial commission by its very existence will enable more collaboration between these stakeholders to the benefit of all. Allied to this are issues related to professionalization. Efforts have been made to offer CGEOG(GIS) via RGS-IBG/AGI but this could be augmented and linked to organisations such as RSPSoc.

- **Long/medium term financial support in HE**

Over the last 30 years the history of government support for geospatial teaching programmes/research in HE has been spatially/temporally very piecemeal with periods of support provided by UKRI via ESRC, NERC and HEFCE. Some schemes have had a research focus (ESRC's RRL initiative) some a teaching focus (NERC PGT support, HEFCE CETLs). Since the withdrawal of NERC-

funding for PGT (level 7) HE in the UK, there has been no direct UKRI supported initiative for the teaching of geospatial skills at level 7. In order to develop geospatial skills appropriately in HE it would be very helpful if such support were available, often translating into student scholarships. . Post-BREXIT, support will be even more critical. In contrast, the USA's NSF has more continuity in terms of centres of excellence funded for longer periods of time, supporting *both* research and teaching.

Q4. Are there any publicly or privately-held geospatial datasets that are currently challenging to access or use or of insufficient quality, but which you or your organisation would find valuable if these issues could be resolved? Please explain why this would be of value, and how access/quality could be improved?

- **OS and ONS data access**

The OS and ONS data holdings are currently not as free of use restrictions as are similar data holdings for example in the USA. As a teacher and researcher in GIS with 20+ years of experience, the difficulties this has generated for my/students use have been profound and necessitated the frequent use of non-UK geospatial data for both teaching and research. Although the situation has improved in recent years with much data becoming available via various forms of OGL, the OGL environment is still complex to disentangle from the end-user perspective, particularly when looking at historic data. In particular there are still OS datasets that are not available under the OGL, and several forms of OGL. The obvious solution would be at least to bring all geospatial data into the *same* OGL framework or, perhaps even more preferable would be to explore options of a data supply framework with even *fewer* restrictions (completely free access).

- **Public data samples**

There is a wide-spread use of datasets from internet platforms (e.g. Twitter) in many fields of research, both quantitative and qualitative. The fact that every researcher is required to collect their own data from these platforms is problematic in two core aspects. First, it creates a reproducibility issue, as well as a transparency one, as datasets are different for each piece of research and inaccessible to other researchers. Second, it creates a divide between researchers and institution that can invest time, money, and equipment in collecting and maintaining the dataset, and those that cannot. A public sample dataset of the most used dataset made available by a government agency would provide a common point of reference for all the work in a variety of fields in geography, computer science, social sciences, and more.

Q5: Do you anticipate that any changes will be needed to the both address data and the wider address ecosystem, to support emerging technologies? Please provide evidence of value to support any proposed changes.

No comment.

Q6: How should the commission be looking to develop the UK's capability in Earth observation data, both technologically and to support an effective market?

- **Long/medium term financial support in HE**

Again, I would argue that supporting HE with funding for specialist geospatial programmes (both taught and research) would facilitate the flow of professionals into the sector.

- **Accessible analysis-ready data**

Certainly the current trend toward analysis ready data for EO ought to be continued. One of the historic problems (well-known in the EO community over the last 20 years) is that the ability to *collect* data outstrips the ability to analyse. Hence, archived data ought to be as open as possible to allow maximum use. The reference to US Landsat data (page 16 in the call for evidence document) conveniently (possibly accidentally) reinforces the point of EO data from the US being historically much more accessible than UK/EU products.

Q7. Which new technologies should the commission focus on to provide new opportunities to process and exploit geospatial data for economic growth?

- **Drones**

Drone technologies/UAVs have revolutionised the real time collection of imagery over small areas/largely scales. Supporting the sensible use of such technology, including an appropriate legislation framework for collection and use of derived data could be one avenue.

Q8. How can geospatial data and applications be used to support enhanced roll-out of future technologies?

- **Open access data**

Clearly, more accessible data would encourage technology roll-out. There seems limited use in developing proof-of-concept technologies which are dependent on often expensive (and possibly prohibitively restrictive) data licences!

Q9: What are the options for how public sector organisations could continue to invest in maintaining and enhancing our geospatial data assets?

No comment.

Q10: What areas of the underpinning geospatial infrastructure such as positioning technologies, including GPS and indoor positioning systems, and geodetic networks and frameworks to support them, should we be prioritising the development of, in order to support the emerging requirements for geospatial data?

- **GNSS access**

The answer to this very much depends on the outcome of BREXIT negotiations and our access (or not) to GALILEO/something similar. Clearly the UK will require a similar level of access to GNSS data to that it currently enjoys..

Q11: What role should the private sector have in both the development and maintenance of the underpinning infrastructure and enhancing the UK's geospatial data assets?

- **Core infrastructure**

The core infrastructure and R&D should be directly maintained by the government/public sector. It is unlikely that the continuity of service/supply could be guaranteed in any other way.

- **Public/private joint ventures**

Obviously the private sector needs to be involved in R&D and in this case, this may be best served in the form of public-private joint-ventures.

Q12. Do you face challenges when working with geospatial data from across the public sector? If so, what are they and how could value be better released? Are there any technical remedies or standards that could be adopted to improve the interoperability of geospatial data? Please provide supporting evidence of what these remedies could help to accomplish.

- **Data accessibility**

Make *more* geospatial data available through https://data.gov.uk

- **Harmonise licencing**

For example, the OGL licence is available in three versions (plus Welsh)! See http://www.nationalarchives.gov.uk/doc/open-government-licence/version/3/

- **Harmonise interoperability of standards and metadata**

Q13. How can the Geospatial Commission act as a more effective customer for geospatial data on behalf of the public sector?

- **Broker data access agreements**

If there is no default open data option then, the geospatial commission should act as a data access broker for the whole public sector.

Q14. Are there any additional geospatial datasets, from the other partner bodies or other sources, that the public sector would derive significant benefit from having access to, that might have novel and valuable use cases? What would that access look like?

- **Health care data**

Although there are clear problems, from the perspective of use of geospatial data in a public health context, better access to health care data (where possible) would be beneficial.

Q15: How can we best develop a single UK strategy, ensuring alignment between the individual strategies across the UK while still allwoing for regional variations?

No comment

Q16: How can we best ensure effective local authority coordination and sharing of best practise, using location data to better deliver public services?

No comment

Q17: As a result of this analysis, we are prioritising the exploration of possible initiatives in the high-value categories identified:

- **property and land**
- **infrastructure and construction**

- **mobility**
- **natural resources**
- **sales and marketing**

What are the existing or potential geospatial applications which could be scaled-up or developed in order to capture economic value? (We would particularly welcome responses from industry and other bodies engaged in these sectors.)

No comment

Q18: Are there any other areas that we should look at as a priority?

- **Environment**

Although 'natural resources' may cover elements of the environment, both natural environments and social (also urban) environments surely warrant specific focus from a variety of contexts (climate change focus, environmental impact of flooding etc). The involvement of the Environment Agency as a key stakeholder would be advisable, particularly since they generate large quantities of geospatial data.

Q19: What are the main potential private and public sector innovations that will rely on the use of geospatial data to rollout, and are there corresponding regulatory challenges?

No comment.

Q20: How best can we make the UK's presence in the international geospatial world more visible?

- **Sustained investment in education**

Medium to long-term strategic investment in training in geospatial skills at all levels of education.

- **Targeted research initiatives**

The constituent bodies making up UKRI mean that anything GIScience/ Geospatial is usually of secondary importance in relation to the primary science mission of bodies such as NERC for example. Geospatial research – if valued – should be reflected by a dedicated funding council/stream or in more radical terms, an equivalent to the US NSF be created which supports both research and teaching in a geospatial context.

Q21: Where should the UK be looking for points of comparison overseas? Who are the other international exemplars? What best practice is being modelled overseas that we can learn from?

- **USA**

In terms of data supply: the USA. For example the US data catalogue available at https://www.data.gov and the Executive Order mandating Open and Machine readable data the default for US government https://obamawhitehouse.archives.gov/the-press-office/2013/05/09/executive-order-making-open-and-machine-readable-new-default-government-

Also in terms of how HE is funded via the NSF which jointly funds research and education https://www.nsf.gov/news/overviews/education/index.jsp

Thank you for your time in completing your response to our call for evidence.

Any questions, please get in touch with the Geospatial Commission via geospatialcommission@cabinetoffice.gov.uk

Geospatial Commission: Call For Evidence Response Questionnaire

Please submit your completed questionnaire to:

geospatialcommission@cabinetoffice.gov.uk.

Clearly title your email *'Call for evidence response'*.

About you and your organisation

Name	[Text redacted]
Organisation	Venture Geomatics Limited
Job title	[Text redacted]
Address	[Text redacted]
E-mail	[Text redacted]
Telephone	[Text redacted]

Please select which of the following best describes you as a respondent:

Respondent	**Please mark with a X**
Academic	
Business representative / trade body	
Central government	
Charity or social enterprise	
Individual	
Legal representative	
Local government	
Large business (over 250 staff)	
Medium business (50 to 250)	
Small business (10 to 49)	
Micro business (up to 9)	**X**
Other - please state	

Call for evidence - three key themes

We have identified three high-level themes that could help our approach to setting a strategy which are as follows:

1. **Supporting innovation in the geospatial sector**, exploring how to secure cutting edge skills, the right access to data, and opportunities from emerging technologies for the geospatial sector itself
2. **Enhancing the UK's geospatial assets,** looking at how best to align interests, avoid duplication, and instill best practice across the whole public sector
3. **Driving investment and productivity in geospatial applications**, asking in which wider sectors the most value lies from better exploitation and use of geospatial data, in the UK and internationally

Our questions

Q1. Is our view of the geospatial data types accurate? If not, what should be included or excluded from this?

The data types being mentioned are only part of the supply chain of Geospatial data from collection and observation & monitoring, quality control and checks, processing and rendering for the end user. This Supply or Value Chain can often be lost if the tone of the term Geospatial data suggests a"GIS" environment focus. However this toolbox is but one of many aspects to Geospatial data processes and uses. The exciting opportunity here is to develop a more comprehensive and cohesive approach across the entire range of data collection & capture, geodetic densification, Planning, Environmental Impact, BIM, digital and virtual twins. The use of data analytics and database technologies that have spatial awareness can be developed so as to ensure that the "Spatial is everywhere" concept can be truly adopted across government departments, private practice and industry.
So the approach appears to cover the traditional elements however the onset of mobility and location based information tools and services is expanding and disrupting this concept especially as the users are increasingly expecting real or near-real time problem solving. This alters the spectrum of the geospatial data delivery landscape to one of an ever present availability with ease of access. As such this will require further development of data standards (formats, content, quality, interoperability) from the sensor data capture across the value chain to the end users' digital twin virtual environment supporting some form of analysis.
The Geospatial Commission has the opportunity to embrace the new technologies of AI/ML, robotics, driverless vehicles, BIM and integrate these into a strategy that does not allow the traditional skills and technologies of data capture, quality control and data delivery to be overshadowed and relegated. Geodesy, survey & measurement, EO & Remote Sensing, Engineering monitoring, GIS and Data Management are all skills and aspects of Geospatial data required in some form to

deliver the UK as no.1.

Q2. In addition to current government policy, what are the areas of geospatial skills where the commission could best focus, to help ensure the necessary capability within the UK for the future?

The general pressure and reduction in the number of under graduate courses offering the appropriate core Geospatial skills (Geodesy, Surveying, Photogrammetry, GIS, Geo Data Management and Cartography) is of concern and although recent initiatives such as the Geospatial Surveying apprenticeships are to be welcomed it does not go to the heart of the issue.
The Geospatial Commission could focus effort in educating and introducing geospatial curricula activities to ALL primary and secondary schools via teacher training packs, pupil learning and activity material and in developing a clear pathway for anybody interested in pursuing Geospatial as a profession. STEM courses are being encouraged and Geospatial is a component of these and the Geospatial Commission should work with DoE to develop and support school and undergraduate courses, which are often comprised of small numbers of students that require access to high value equipment, systems and technologies. The core competencies do need to be the focus and then elective elements on associated elements such as GIS, BIM, Data Analytics (as applied to Spatial), game theory, Remote Sensing, Computer Software coding can be added as desired.
Certificates should be available at all levels (GCSE, A Level, BSc etc). In this way the development of the skills can support the GovTech, unlock value and deliver a world-class Geospatial knowledge base.

Q3. What are the geospatial skills needs and gaps in your organisations, how can these be most effectively addressed, and how can careers in the sector be best promoted?

Beyond the traditional geospatial core competencies (Geodesy, Surveying, Photogrammetry,Data Management and Cartography), new emerging technologies mean organizations and business sectors (as well as government) are creating a demand for Geospatial skills integrated into inter-disciplinary and related sectors. The Geospatial Commission could work to develop both a pan government environment of awareness as well as promoting and encouraging private sector and industry to develop a Geospatial Forum or Alliance in order to better represent and articulate the career prospects and opportunities. By developing a Geospatial curricula for schools and presenting a career path is a start. Thereafter the government should be encouraging the Footsie 100 and other key business groups to appoint Geospatial or Spatial Officers at board room level. Developing a Strategy over say a 10 year (or maybe to 2030) time frame would offer the chance to demonstrate commitment.

Q4. Are there any publicly or privately-held geospatial datasets that are currently challenging to access or use or of insufficient quality, but which you or your organisation would find valuable if these issues could be resolved? Please explain why this would be of value, and how access/quality could be improved?

Many data sets are held in isolation or behind access restrictions. It would be beneficial to empower registered users to have a broad range of discoverable data available for download or even for some analysis. E.g. it would be good to be able to define a search area via a map on a web portal and to see and download all and any data held in relation to that area, whether from the Council, DoT, DoE, Defra, NHS etc.

Q5: Do you anticipate that any changes will be needed to the both address data and the wider address ecosystem, to support emerging technologies? Please provide evidence of value to support any proposed changes.

The emphasis has traditionally been on a horizontal model but more and more 3D representations are becoming a serious requirement. This is an aspect that is likely to challenge many data sets.

Q6: How should the commission be looking to develop the UK's capability in Earth observation data, both technologically and to support an effective market?

The success of the Catapult initiatives could offer a path to developing a Geospatial component for all Catapults – if not a Geospatial Catapult itself. Earth Observation, Remote Sensing, LIDAR and other sensor technologies are enablers to SME innovation and so it is vital that the Geospatial Commission encourages, accelerates and supports access to the sensors, access to the value chain of data and creates an environment for the government and public to be end user beneficiaries.

Q7. Which new technologies should the commission focus on to provide new opportunities to process and exploit geospatial data for economic growth?

The location based industries and some of the automation and transactional technologies are sectors to assess and understand through an audit of the emerging technologies and their potential roles and likely impact over time (short term impact, slow or even a long term impact,) and how they may integrate into the work flows of the future. New sensors with new data capture could be a short term benefit whilst Blockchain and Data Management might be viewed as longer (possibly slower returns) term. Technologies that can remotely monitor or capture data will be a trend that could revolutionise the geospatial industry. In a future of self-driving cars and smart cities much of the data will be collected by the routine day to day activities of vehicles and the public. Consuming and harvesting this wealth of data will be a challenge in a cybersecure GDPR world that could be really beneficial.

Q8. How can geospatial data and applications be used to support enhanced roll-out of future technologies?

Technologies such as the 5G platform coupled with a general increase in the end users mobile environment of new sensors and near and real-time data provision will require a continued effort on the densification of the basic Geodetic framework as well as ensuring that the availability of data for Smart Cities and IoT can be delivered. The creation, adoption and use of digitalization techniques along with Standards for exchange and interoperability of data under a rich metadata umbrella will be vital to support future technologies.

Q9: What are the options for how public sector organisations could continue to invest in maintaining and enhancing our geospatial data assets?

Public Sector investment opportunities could include: 1) Data Capture and Quality 2) a: data standards compliance, b: meta data discipline and rules, c: currency of data and retention rules, 3) Web based availability of data and clustered geospatial data hosting.

Q10: What areas of the underpinning geospatial infrastructure such as positioning technologies, including GPS and indoor positioning systems, and geodetic networks and frameworks to support them, should we be prioritising the

development of, in order to support the emerging requirements for geospatial data?

A solid Geodetic framework is necessary to enable the new technologies and developments to be of value and so priority could be given to the densification of the Geodetic Network and maintaining the Geodetic Network at the highest order of accuracy and connected into a current International Terrestrial Reference Frame that realizes the International Terrestrial Reference System.
The Geospatial Commission should seed development of Indoor and Underground positioning and location methodologies. These should be encouraged and developed in order for the UK to be world no.1 in Geospatial.

Q11: What role should the private sector have in both the development and maintenance of the underpinning infrastructure and enhancing the UK's geospatial data assets?

Ref Q.10 above. However some aspects of the services related to the Geodetic Network could be undertaken with the private sector. Subject Matter Experts within innovative groups in private sector can be encouraged to develop technologies, for subsurface and indoor positioning. Complex challenges and shared developments to achieve solutions could be developed through the use of Geospatial clusters and regional hubs. Business sector leaders need to be encouraged partly through recognition of their contribution but also with collaborative enterprises with targets in relation to the UN Sustainable Development Goals should be introduced.

Q12. Do you face challenges when working with geospatial data from across the public sector? If so, what are they and how could value be better released? Are there any technical remedies or standards that could be adopted to improve the interoperability of geospatial data? Please provide supporting evidence of what these remedies could help to accomplish.

There is still not enough cohesion for a geospatial end user when accessing data for an area. Too many silos and multiple licencing regimes create delays and friction.

Q13. How can the Geospatial Commission act as a more effective customer for geospatial data on behalf of the public sector?

The Geospatial Commission should promulgate the concept of each and every government department having a Geospatial Officer or at least a Subject Matter Expert. Geospatial should be an integral part of any departmental strategy, website and calls for tendering, innovation and services.

Q14. Are there any additional geospatial datasets, from the other partner bodies or other sources, that the public sector would derive significant benefit from having access to, that might have novel and valuable use cases? What would that access look like?

Data sets relating to planning and development should be spatially enabled. The Rural Payments Agency data could be made available as could Crown Estates and effort applied to enable the underground utilities to make their data available. Web design, portals and local authority libraries could act as entry points for a spatial query and offer a visual experience of the spatial results via standard delivery services and associated data downloads. National Data Centres or Data Hubs could be explored.

Q15: How can we best develop a single UK strategy, ensuring alignment between the individual strategies across the UK while still all*ow*ing for regional variations?

The Geospatial Commission could support combined industry and government seminars and workshops to raise and discuss key strategic elements and through peer groups, regional government representation and private sector industry representation create a geospatial Forum or Alliance to provide a platform for developing strategies appropriate for that region. Clustered geospatial groups in public and private sectors would develop and implement elements of these strategies leading to cross sectorial benefits.

Q16: How can we best ensure effective local authority coordination and sharing of best practise, using location data to better deliver public services?

Seed coordination and collaboration to cut costs at a policy and strategic level, aim to develop and improve efficiencies and generate a cohesive approach to unlock gains and benefits at the services level that interface to end users and the public.

Q17: As a result of this analysis, we are prioritising the exploration of possible initiatives in the high-value categories identified:

- **property and land**
- **infrastructure and construction**
- **mobility**
- **natural resources**
- **sales and marketing**

What are the existing or potential geospatial applications which could be scaled-up or developed in order to capture economic value? (We would particularly welcome responses from industry and other bodies engaged in these sectors.)

Property & Land: Applications relating to transactions and assessment of taxation, concerned with land and property valuation, establishing values of Compensation and supporting Planning & development.
Infrastructure and Construction: The OSNet Geodetic Network densification, Monitoring change detection with EO and RS data, developing underground positioning and data capture, BIM & GIS with Digital Twins and Smart Cities.
Natural Resources: Supporting the development of Micro Power Grids, flood prediction, mitigation and avoidance, Electric vehicle charging points, Renewables from ocean currents, tides and waves, transportation route planning, waste and recycling.
Mobility: The planning and analysis of transportation needs, emergency response efficiency, machine learning & Robotics and smart asset tracking, digital device apps for end user groups re spatial events, risks, news.

Q18: Are there any other areas that we should look at as a priority?

The issue surrounding the existing data sets and how we might envisage these becoming available for professional and public use is offset by the potential for a growing platform of high mobility and short term currency of new data sets being captured. How and what data should be retained and managed needs to be investigated in the context of an ever increasing public data capture capability with self-determining results over-riding or bypassing rich but perhaps less dynamic database environments.

Q19: What are the main potential private and public sector innovations that will rely on the use of geospatial data to rollout, and are there corresponding regulatory challenges?

Changing markets re power generation & usage, environmental impact, BIM, Smart Cities, transportation and general geospatial Information Services and the growing awareness of the UN-SDG's, plus the expectation of access to Geospatial data will alter (increase) the demand for integrated data solutions in real (or very near real) time. Integrated and joined up collaborative developments and solutions that are cross sector will have enormous potential if the data can be accessed and shared within the innovating groups. The regulatory framework will follow and build upon the stressors and pinch points of the new methodologies but throughout the quality of the data must be a priority and our skills must be developed to ensure that the richness and value of the data is sustained.

Q20: How best can we make the UK's presence in the international geospatial world more visible?

The UK needs to re-establish itself as the premier Geospatial academic provider through leading academic foundations and institutes delivering under-graduate and post-graduate opportunities for the UK to develop it's expertise and to offer opportunities for International relations and students. (centres do or have existed: Durham – boundaries, Nottingham – IESSG, Glasgow – Topographic, Cartography and Photogrammetry Diplomas).

Q21: Where should the UK be looking for points of comparison overseas? Who are the other international exemplars? What best practice is being modelled overseas that we can learn from?

There are numerous nations developing strong geospatial strategies and policies. In no particular order there are interesting developments in:

Canada: Spatial Strategy
France: Innovation within an EU context
Singapore: National Spatial Strategy
Japan: Regional plans
Ireland: National seabed survey across its extended EEZ with free data access
USA: Federal Geospatial plan in relation to their SDI.

Thank you for your time in completing your response to our call for evidence.

Any questions, please get in touch with the Geospatial Commission via geospatialcommission@cabinetoffice.gov.uk

National Geospatial Strategy – Call for Evidence
Vodafone response

Overview

Vodafone supports the broad statement that 'the data revolution is changing the way we see the world and the way we live our lives'.

Technologies such as AI, blockchain, cloud and edge computing are shaping how we create, access, use, move and store data about ourselves and our environment, while the connectivity of the Internet of Things and our forthcoming 5G networks are making intelligent applications available anywhere and everywhere. The increasing volumes of machine made data along with any subsequent machine created 'exhaust data' can also create interesting projects that have positive economic benefit.

Vodafone is committed to helping build a global data-driven economy. We already share insights from mobile network data with public sector bodies, often on a voluntary basis. We also encourage best practice in the sharing of machine generated non-personal data between different private sector companies in the data driven economy supply chain.

Vodafone Location Insight

Vodafone is helping delivery broader societal benefits through a number of ongoing initiatives, in particular Vodafone Location Insight. The programme provides a sophisticated way to count people and journeys derived from pseudonymised location data sourced from our mobile network.

The Welsh Government was an early adopter of this new approach and it has made use of Vodafone Location Insight to update their regional transport model and other transport projects. Surveys that involve stopping drivers on the road were not feasible for cost and safety reasons and during a 6-week study Vodafone was able to measure six million journeys within the South East Wales Region. This allowed us to build an accurate picture of how people travel around the area. All results and insights were provided to the Welsh Government as aggregate counts in a format that feeds directly into their transport models and other transport planning tools. No personally identifiable information is ever shared.

- We would advocate you watch this short, (sub 4 minute video) about our engagement with the Welsh Government: https://www.youtube.com/watch?v=fj353Sj8zdI
- Vodafone would like to confirm we are open to a similar discussion/engagement with other parts of the UK Government.

Other key use cases include:

Local Transport Studies: we have worked with leading engineering consultancies to replace legacy survey techniques with a virtual capability, an approach that is now proving far more effective than the traditional techniques. Our work with the regional government of Wales is particularly noteworthy; where we have developed advanced transport analysis techniques for use in the strategic planning of their new infrastructure programme. Outputs included travel demand matrices covering the whole country at LSOA level (Lower Super Output Areas) including information on origin, destination, mode of travel, reason for travel, time of the day and day of the week.

Airport Planning: in December 2015, the Vodafone Location Insight team worked with Citi Logik and Heathrow Airport to develop travel demand matrices covering the South of England. These matrices, provided by mode, purpose, time of the day and day of the week will be used as underlying data to develop the new transport model to be used to support the proposed Heathrow expansion and planning of the third runway and implications it might have on surface access to the airport and interactions with local communities and transport infrastructure.

The contract was awarded on a value for money basis and required our team to analyse data collected for an area covering about 15 million people. 22 billion raw events were recorded during the period, of which approximately 8 billion were identified as collected from mobile devices in movement. In total, over the course of the 60-day survey period, data from 6.5 million unique mobile devices was analysed, this corresponds to sampling about 30% of the population. The project has now been completed supported by Mott McDonald and AECOM.

A similar programme of work has also been completed for London Gatwick in conjunction with Arup. We sampled device trips from across the UK, analysing journeys to the airport by identifying trips via the various road and rail corridors surrounding it. Information was provided separating locals and workers and irregular visitors in a bid to understand how the airport impacts on the local transport infrastructure. Data will be used to provide insight for the Gatwick Airport Surface Access Strategy (ASAS).

Office for National Statistics – Administrative Data Program: for the past 18 months Vodafone Location Insight has been supporting research activity with ONS to data can be used to measure real-time commuting flows. The first phase of this project was conducted between March and April 2016 and all data outputs were made available via the ONS website to encourage feedback on the methodology and call for ideas for improvements and applications of the data for social and economic good. https://www.ons.gov.uk/methodology/methodologicalpublications/generalmethodology/onsworkingpaperseries/onsmethodologyworkingpaperseriesno8statisticalusesformobilephonedataliteraturereview

The data is being used as part of the ONS Administrative Data Program to replace existing field data surveys. The UK Office for National Statistics spends £500m conducting the census (the estimate for the US census in 2020 is $16B – probable equivalent to cost across EU 27). Big Data has the potential to reduce this cost significantly and for the first time in history our geo spatial data is enabling ONS to measure human demand on cities and public infrastructure in a statistically robust and meaningful way without the requirement to send a survey to every household.

Connected Cities: we have completed a number of projects in the UK to provide assessment of congestion in and around cities. This included analysis of multi modal movement of vehicles arriving into car parks and then transiting into the city centre within a city with severe congestion (Exeter), a port trying to alleviate congestion and improve the city centre connectivity (Liverpool) and a large city (Manchester) seeking to exploit the ideas across multiple challenges. The benefits enabled planners to

make informed decisions to enable successful transport planning for their cities, as well as highlighting popular journey routes and wider understanding of who is using the facilities. This supported the business case for future investment and ensured that budgets were being allocated to the most relevant and beneficial areas.

Industry leading data security

Vodafone has developed a comprehensive framework of technical and organisational controls to ensure that data is only processed for purposes which have been agreed with customers. In addition to navigating a complex set of horizontal and non-harmonised sector specific privacy rules (e.g. on data quality, customer permissions and data retention), Vodafone has to develop technology solution which caters for these diverse requirements.

Our services fully anonymise and aggregate data relating to movement of groups of people and transport derived from the existing mobile network infrastructure to enable data driven decision making for organisations engaged in transport planning, transport operations, smarter cities, retail planning and the built environment.

The controls cover the entire data lifecycle from notice to collection, use and deletion. All intended uses of data are relayed to customers through contextualised and layered privacy notices and required permissions are sought. Customers can manage them anytime through permissions portal. All data are pseudonymised with comprehensive algorithms prior to ingestion to analytics platform. At ingestion all data is documented and the rights and obligations related to the data carry over to analytics platform (e.g. permitted purposes, consents and retention, and are dynamically kept up to date).

All use cases are subject to Use Case Privacy and Ethics Review by experts. Non-permissioned data is filtered automatically from a given use case. Analysts must sign the Vodafone Code of Analysts Ethics prior to getting access. Our approach on Privacy by Design for Data Analytics offers true privacy protection to Vodafone customers in an industry leading manner, ensures full compliance with GDPR and ePrivacy rules.

In all of our Location Insight products, our insights are never about the individual, only the population as a whole and are always presented to our clients in an aggregate form. Vodafone never shares the actual raw data with customers of location insights. Instead, we help organisations find answers to their questions through our privacy enabled analytics service by providing anonymous insights.

Please select which of the following best describes you as a respondent:

Respondent	**Please mark with a X**
Academic	
Business representative / trade body	
Central government	
Charity or social enterprise	
Individual	
Legal representative	
Local government	
Large business (over 250 staff)	
Medium business (50 to 250)	
Small business (10 to 49)	
Micro business (up to 9)	

Other - please state	Cross-sector partnership

Call for evidence - three key themes

We have identified three high-level themes that could help our approach to setting a strategy which are as follows:

1. **Supporting innovation in the geospatial sector**, exploring how to secure cutting edge skills, the right access to data, and opportunities from emerging technologies for the geospatial sector itself
2. **Enhancing the UK's geospatial assets,** looking at how best to align interests, avoid duplication, and instill best practice across the whole public sector
3. **Driving investment and productivity in geospatial applications**, asking in which wider sectors the most value lies from better exploitation and use of geospatial data, in the UK and internationally

Our questions

Q1. Is our view of the geospatial data types accurate? If not, what should be included or excluded from this?

-

Q2. In addition to current government policy, what are the areas of geospatial skills where the commission could best focus, to help ensure the necessary capability within the UK for the future?

In the context of a degrading natural environment, plummeting biodiversity (e.g. over half our species have declined since 1970 – State of Nature report) and a changing climate, the Government has committed to improve our natural environment for the next generation. The Industrial Strategy acknowledges the importance of a healthy natural environment for a resilient economy – after all, there is no business on a dead planet. Local planning authorities have a statutory duty to protect and conserve biodiversity, which in turn relies on an effective environmental evidence system.

Commitments to achieving net gains in biodiversity and other ecosystem services are absolutely critical, and strongly welcomed. However, there are significant challenges in delivering these commitments, and holding decision makers to account, due to significant data blind spots and inconsistencies of methodology, capacity and capability across the country. This is in part how our national environmental data systems operate, with insufficient funding and leadership from

central government. Nationally, the environmental data landscape is highly fragmented. Local environmental evidence for planning and policy purposes is largely provided through Local Environmental Records Centres (of which there are around 50 across the country and which, having organically developed, adopt different data frameworks) alongside some standardised national datasets (e.g. Ordnance Survey, Natural England, Environment Agency).

However, there are few overarching standards for environmental data infrastructure and indicators at the micro level (needed to meaningfully demonstrate 'net gain'), in turn limiting the ability to compare trends across regions and over time, to apply modelling and AI to fill in data gaps, and otherwise effectively draw on learnings from elsewhere. This results in a limited understanding of our natural environment, especially at the landscape scale, as well as being a highly resource-intensive model to manage – which compromises our ability to deliver on Government's ambitions and key policy as highlighted above.

We would strongly ask that the Commission takes special consideration of how it could provide leadership in a significantly more strategic and effective approach to understanding, managing and enhancing our natural environment for the benefit of our society and economy.

Q3. What are the geospatial skills needs and gaps in your organisations, how can these be most effectively addressed, and how can careers in the sector be best promoted?

In the transition to a more effective national environmental evidence system – that focuses on moving beyond data collection to delivering the best insights and information to enhance our natural environment for the benefit of us all – the sector needs skills in GIS, remote sensing and machine learning for effective modelling, but also skills to capture and monitor the state of wildlife in the first place. In the case of the West of England, we rely on volunteers (which is an ageing demographic) for about 70% of our wildlife records.

Q4. Are there any publicly or privately-held geospatial datasets that are currently challenging to access or use or of insufficient quality, but which you or your organisation would find valuable if these issues could be resolved? Please explain why this would be of value, and how access/quality could be improved?

A particular challenge for the West of England, and shared by other Local Nature Partnerships across the country, is access to a high-quality and freely available standard land cover map (specifying, in sufficiently high granularity for meaningful planning decisions, habitats and land use). As a land cover map is the foundation for the vast majority of ecological and environmental monitoring and modelling, without a high quality and standardised base map, resulting mapping for decision

making can be inconsistent across borders, and is inefficient due to the time and resource involved in each region developing its own land cover map. Furthermore, the nature of environmental restoration is partnership working, and licences limiting data access (e.g. PSMA) can create barriers in wider stakeholders using the same evidence base.

Q5: Do you anticipate that any changes will be needed to the both address data and the wider address ecosystem, to support emerging technologies? Please provide evidence of value to support any proposed changes.

More centralised leadership as above

Q6: How should the commission be looking to develop the UK's capability in Earth observation data, both technologically and to support an effective market?

More centralised leadership as above

Q7. Which new technologies should the commission focus on to provide new opportunities to process and exploit geospatial data for economic growth?

Machine learning and remote sensing to support building a more intelligent and complete picture of our ecosystems, with the caveat that ecology is hugely complex and cannot be fully captured by modelling.

Q8. How can geospatial data and applications be used to support enhanced roll-out of future technologies?

-

Q9: What are the options for how public sector organisations could continue to invest in maintaining and enhancing our geospatial data assets?

-

Q10: What areas of the underpinning geospatial infrastructure such as positioning technologies, including GPS and indoor positioning systems, and geodetic networks and frameworks to support them, should we be prioritising the development of, in order to support the emerging requirements for geospatial data?

-

Q11: What role should the private sector have in both the development and maintenance of the underpinning infrastructure and enhancing the UK's geospatial data assets?

-

Q12. Do you face challenges when working with geospatial data from across the public sector? If so, what are they and how could value be better released? Are there any technical remedies or standards that could be adopted to improve the interoperability of geospatial data? Please provide supporting evidence of what these remedies could help to accomplish.

-

Q13. How can the Geospatial Commission act as a more effective customer for geospatial data on behalf of the public sector?

-

Q14. Are there any additional geospatial datasets, from the other partner bodies or other sources, that the public sector would derive significant benefit from having access to, that might have novel and valuable use cases? What would that access look like?

-

Q15: How can we best develop a single UK strategy, ensuring alignment between the individual strategies across the UK while still allowing for regional variations?

-

Q16: How can we best ensure effective local authority coordination and sharing of best practise, using location data to better deliver public services?

-

Q17: As a result of this analysis, we are prioritising the exploration of possible initiatives in the high-value categories identified:

- **property and land**
- **infrastructure and construction**
- **mobility**
- **natural resources**
- **sales and marketing**

What are the existing or potential geospatial applications which could be scaled-up or developed in order to capture economic value? (We would particularly welcome responses from industry and other bodies engaged in these sectors.)

-

Q18: Are there any other areas that we should look at as a priority?

As per response to Q2, we would strongly ask that the Commission takes special consideration of how it could provide leadership in a significantly more strategic and effective approach to understanding, managing and enhancing our natural environment for the benefit of our society and economy.

Q19: What are the main potential private and public sector innovations that will rely on the use of geospatial data to rollout, and are there corresponding regulatory challenges?

As above, sufficiently effective data systems are required to enable us to restore and enhance our natural environment for our own resilience and that of future generations. As environmental evidence systems in the UK are highly fragmented, central leadership is required to enable the innovations required in turning data to information, and truly influencing decisions on the ground.

Q20: How best can we make the UK's presence in the international geospatial world more visible?

-

Q21: Where should the UK be looking for points of comparison overseas? Who are the other international exemplars? What best practice is being modelled overseas that we can learn from?

Geospatial Commission: Call For Evidence Response Questionnaire

Please submit your completed questionnaire to:

geospatialcommission@cabinetoffice.gov.uk.

Clearly title your email *'Call for evidence response'*.

Call for evidence - three key themes

We have identified three high-level themes that could help our approach to setting a strategy which are as follows:

1. **Supporting innovation in the geospatial sector**, exploring how to secure cutting edge skills, the right access to data, and opportunities from emerging technologies for the geospatial sector itself
2. **Enhancing the UK's geospatial assets,** looking at how best to align interests, avoid duplication, and instill best practice across the whole public sector
3. **Driving investment and productivity in geospatial applications**, asking in which wider sectors the most value lies from better exploitation and use of geospatial data, in the UK and internationally

Our questions

Q1. Is our view of the geospatial data types accurate? If not, what should be included or excluded from this?

I think they are good definitions of things which are hard to define. Whilst the term geospatial would be unfamiliar to most people, alternatives would be too exclusive or misleading about what is covered.

Q2. In addition to current government policy, what are the areas of geospatial skills where the commission could best focus, to help ensure the necessary capability within the UK for the future?

Formal geospatial related qualifications provide a good foundation to the wide ranging subjects of geospatial data and skills, but recruitment in GIS focuses on skills and experience. The qualifications are often done after someone has already started (knowingly or otherwise) a GIS role and are looking to develop.

I feel there are already good quality courses and resources available for those wanting to learn more about geospatial data, it is the limited numbers interested in geospatial which hinders are future geospatial capability. The sparsity of geospatial roles deters talented individuals from taking up the specialism, especially when careers as developers or analysts give so many more opportunities. If the UK is to have the future geospatial capability needed then I would encourage the commission to focus on supporting the creation of geospatial opportunities from entry level to specialist roles, across all parts of the country, in local government and private industry. Once this demand is there then the talent will follow and there is already plenty in place to support those wanting a career in this area.

Q3. What are the geospatial skills needs and gaps in your organisations, how can these be most effectively addressed, and how can careers in the sector be best promoted?

Like many others who work in GIS, I got into the subject area because I did one small module on GIS during a degree. If geospatial could feature in computer science and data scientist type degrees then maybe more people might know about the subject. Even where this doesn't result in them wanting to start a career in GIS, it may help communication between future deveopers/ analysts and those working in geospatial roles.

Q4. Are there any publicly or privately-held geospatial datasets that are currently challenging to access or use or of insufficient quality, but which you or your organisation would find valuable if these issues could be resolved? Please explain why this would be of value, and how access/quality could be improved?

The ability to quickly and easily identify who owns a piece of land, which is free at the point of use, would be of imense value to public servants and greatly improve the service they can provide to the public. For example: council officers being able to quickly contact the owners of land which is being complained about. This would also be useful to those who work in the emergency services, such as fire safety officers. Whilst I understand the need for the Land Registry to protect it's revenue, if this could be centrally funded and made available to all local government I think it would improve services to the public.

Generally there can be a lack of currency, accuracy and completeness to datasets held in local government which may be important to planning future infrasture and innovation, examples might be car parking spaces, street lights, or bins. Datasets which might be nationally important to support the planning and operation of new and innovative technology might need mandatory standards to ensure it will be fit to support this.

Q5: Do you anticipate that any changes will be needed to the both address data and the wider address ecosystem, to support emerging technologies? Please provide evidence of value to support any proposed changes.

Could definitive address data be made easier to access? If the UPRN was made easily available to the public via the ways they currently search for locations, perhaps it could be used more readily in interactions between them and the public sector.

Q6: How should the commission be looking to develop the UK's capability in Earth observation data, both technologically and to support an effective market?

Sorry, run out of time…

Q7. Which new technologies should the commission focus on to provide new opportunities to process and exploit geospatial data for economic growth?

Q8. How can geospatial data and applications be used to support enhanced roll-out of future technologies?

Q9: What are the options for how public sector organisations could continue to invest in maintaining and enhancing our geospatial data assets?

Q10: What areas of the underpinning geospatial infrastructure such as positioning technologies, including GPS and indoor positioning systems, and geodetic networks and frameworks to support them, should we be prioritising

the development of, in order to support the emerging requirements for geospatial data?

Q11: What role should the private sector have in both the development and maintenance of the underpinning infrastructure and enhancing the UK's geospatial data assets?

Q12. Do you face challenges when working with geospatial data from across the public sector? If so, what are they and how could value be better released? Are there any technical remedies or standards that could be adopted to improve the interoperability of geospatial data? Please provide supporting evidence of what these remedies could help to accomplish.

Q13. How can the Geospatial Commission act as a more effective customer for geospatial data on behalf of the public sector?

Q14. Are there any additional geospatial datasets, from the other partner bodies or other sources, that the public sector would derive significant benefit from having access to, that might have novel and valuable use cases? What would that access look like?

Q15: How can we best develop a single UK strategy, ensuring alignment between the individual strategies across the UK while still allwoing for regional variations?

Q16: How can we best ensure effective local authority coordination and sharing of best practise, using location data to better deliver public services?

Q17: As a result of this analysis, we are prioritising the exploration of possible initiatives in the high-value categories identified:

- **property and land**
- **infrastructure and construction**
- **mobility**
- **natural resources**
- **sales and marketing**

What are the existing or potential geospatial applications which could be scaled-up or developed in order to capture economic value? (We would particularly welcome responses from industry and other bodies engaged in these sectors.)

Call for evidence - three key themes

We have identified three high-level themes that could help our approach to setting a strategy which are as follows:

1. **Supporting innovation in the geospatial sector**, exploring how to secure cutting edge skills, the right access to data, and opportunities from emerging technologies for the geospatial sector itself
2. **Enhancing the UK's geospatial assets,** looking at how best to align interests, avoid duplication, and instill best practice across the whole public sector
3. **Driving investment and productivity in geospatial applications**, asking in which wider sectors the most value lies from better exploitation and use of geospatial data, in the UK and internationally

Our questions

Q1. Is our view of the geospatial data types accurate? If not, what should be included or excluded from this?

Data types seem accurate.
Not specifically mentioned is the subsurface for which geospatial data is critical in locating and analysing resources both mineral, liquid (water and oil for example) and gas; and processes within the subsurface. Processes include geological movements, water flows, ground stability and many others.

Q2. In addition to current government policy, what are the areas of geospatial skills where the commission could best focus, to help ensure the necessary capability within the UK for the future?

The proposed skill areas outlined are excellent. What would also help is a government produced online short course/slides shown how to quickly access and use the most widely available geospatial tools available. For example, how download information from an API, how to process the data and then upload and undertake simple processing in ESRI Arc, Google maps, MapInfo etc.

Q3. What are the geospatial skills needs and gaps in your organisations, how can these be most effectively addressed, and how can careers in the sector be best promoted?

Software is difficult to access and use. It is also very expensive. These are the main barriers to use. Training is limited due to the cost and time required. We would certainly make better use of GIS if it was more easily accessible.

Careers could be promoted by linking geospatial data to existing tasks/jobs. Here it would enhance the role being undertaken by enabling better insights into the task rather than promoting geospatial data manipulation.

Q4. Are there any publicly or privately-held geospatial datasets that are currently challenging to access or use or of insufficient quality, but which you or your organisation would find valuable if these issues could be resolved? Please explain why this would be of value, and how access/quality could be improved?

Many datasets are hard to access.
The Environment Agency hold useful data, and some is available. However, it requires the user to have knowledge of API systems to access the data. Also, access is now limited to 28 days in the past for groundwater level data. This data is of immense importance for investigating, analysing, managing and using groundwater resources – a critical part of the UKs water resources.

To aid access a simple interface - probably geographical itself but not necessarily so – that allows a user to select several observation points and a date range and download the data in a simple format such as CSV or Excel would help. JASON format is good for computers and programmers, difficult for others to use.

Geophysical data collected by oil and gas companies would help in analysing geological structure and help understand groundwater flow. This data though, even old data is often kept confidential – it would be good if government could

encourage an open data approach with these organisations.

If frequently updated land use and ground elevation data are of value for lookin at changes that could represent major development or subsidence, threats to water flow or quality. This data is available but difficult to access, slow to download and needs a good knowledge of systems allow tiles to be stitched together to make useful datasets.

Use of subsurface data to generate geological models and accompanying 3D pdfs is an excellent tool for engaging with non-specialists. The ability to make the processing and manipulation of the data would reduce cost and increase access to such products.

Q5: Do you anticipate that any changes will be needed to the both address data and the wider address ecosystem, to support emerging technologies? Please provide evidence of value to support any proposed changes.

Don't tend to use 'street' address in relation to hydrogeology. However, as an organisation this is critical data and improved integration would be very useful. We could more easily find burst pipes, problems at customers addresses, locating remoted customers and generally improve our service to our customers.

Q6: How should the commission be looking to develop the UK's capability in Earth observation data, both technologically and to support an effective market?

The obvious answer is increased collaboration with ESA. The obvious problem is Brexit.
Otherwise, support to Aerospace and UK/EU GIS developers would be useful.

Q7. Which new technologies should the commission focus on to provide new opportunities to process and exploit geospatial data for economic growth?

There are developing new technologies for subsurface imaging. Tremino passive seismic is a cost effective rapid system for shallow subsurface imaging and could be rapidly enhance to provide improved understanding of the geology important for UKs water supplies and a wide range of other purposes.

Q8. How can geospatial data and applications be used to support enhanced roll-out of future technologies?

May help with remote asset survey eg with drones.

Q9: What are the options for how public sector organisations could continue to invest in maintaining and enhancing our geospatial data assets?

Make simple access to all databases stored within organisations without so much worry that the data is 100% accurate. If appropriate warnings are given the risks from the small amount of error are outweighed by the benefits of access to the information.

Q10: What areas of the underpinning geospatial infrastructure such as positioning technologies, including GPS and indoor positioning systems, and geodetic networks and frameworks to support them, should we be prioritising

the development of, in order to support the emerging requirements for geospatial data?

Improvements in GPS are the priority.

Q11: What role should the private sector have in both the development and maintenance of the underpinning infrastructure and enhancing the UK's geospatial data assets?

Private sector should be enabling suppliers to government. Government should set the policy and control the deployment of systems via national systems with as much as possible free access.

Q12. Do you face challenges when working with geospatial data from across the public sector? If so, what are they and how could value be better released? Are there any technical remedies or standards that could be adopted to improve the interoperability of geospatial data? Please provide supporting evidence of what these remedies could help to accomplish.

Data access of labyrinthine and there are no simple interfaces to access the data. The data does not have to be consistent but an easy way to see what is available then then a quick link to access it would be a major step forward. Also, list of lots of datasets, most of which are 'un-published' or inaccessible does not help.

Q13. How can the Geospatial Commission act as a more effective customer for geospatial data on behalf of the public sector?

Support open access to data.

Q14. Are there any additional geospatial datasets, from the other partner bodies or other sources, that the public sector would derive significant benefit from having access to, that might have novel and valuable use cases? What would that access look like?

No comment.

Q15: How can we best develop a single UK strategy, ensuring alignment between the individual strategies across the UK while still allwoing for regional variations?

There is a risk that one national strategy will hamstring the role out of individual datasets by generating large projects to ‘standardise’ data that is often just different.
An overarching set of guidelines with support for local, regional and organisation specific products is the preferred approach.

Q16: How can we best ensure effective local authority coordination and sharing of best practise, using location data to better deliver public services?

Encourage open access to data and provide support to LAs in developing systems.

Q17: As a result of this analysis, we are prioritising the exploration of possible initiatives in the high-value categories identified:

- **property and land**
- **infrastructure and construction**
- **mobility**
- **natural resources**
- **sales and marketing**

What are the existing or potential geospatial applications which could be scaled-up or developed in order to capture economic value? (We would particularly welcome responses from industry and other bodies engaged in these sectors.)

Capture and use of geophysical data – passive and active seismic, remote sensing (gravity/magnetic), enhance groundwater level monitoring to support water resource management.
3D geological models of the whole of UK to support groundwater flow and quality management and manage landuse to support agriculture whilst protecting water resources.

Q18: Are there any other areas that we should look at as a priority?

Some geological data is very out of date. A programme to bring all UK geology mapping into 21st century would be welcomed.

Q19: What are the main potential private and public sector innovations that will rely on the use of geospatial data to rollout, and are there corresponding regulatory challenges?

Better mapping of buried infrastructure to improve management both within and across sectors. The is primarily for water, gas and electricity distribution networks.
Better land use mapping using satellite data to improve the management of risk to water supplies from built development and changes in agriculture.

Q20: How best can we make the UK's presence in the international geospatial world more visible?

Ensure we remain integrated with European groups and systems.

Q21: Where should the UK be looking for points of comparison overseas? Who are the other international exemplars? What best practice is being modelled overseas that we can learn from?

US eg ESRI/Google
EU ESA
EU has many smaller often free to use developers whose products are excellent but need support to make them more visible. This type of development often breeds innovation with easy use and should be encouraged and supported in the UK.
