Weekly national Influenza and COVID-19 surveillance report

Week 43 report (up to week 42 data)
22 October 2020
Executive summary

This report summarises the information from the surveillance systems which are used to monitor Coronavirus Disease 2019 (COVID-19), influenza, and other seasonal respiratory viruses in England. References to COVID-19 represent the disease name and SARS-CoV-2 represent the virus name. The report is based on data from week 42 (between 12 and 18 October 2020) and for some indicators daily data up to 20 October 2020.

Several surveillance indicators suggest that COVID-19 activity at a national level has continued to increase during week 42, though there are some indications that infection rates may have started to decline in some age cohorts. There is currently limited testing for other respiratory viruses, however, laboratory indicators suggest that influenza activity is low and rhinovirus activity has decreased over the past four weeks.

Detections of COVID-19 cases in England remained high but stable in week 42. Incidence and positivity rates remain highest in the North of England but there have been declines in positivity in some areas including the North East and East Midlands. By age group, cases rates remain highest in the 10 to 19 and 20 to 29 year olds although rates in these age groups have begun to decline. Positivity rates were highest in the 10-19 year olds tested through both Pillar 1 (NHS and PHE testing) and Pillar 2 (community testing) but have also begun to decline in week 42.

Through Respiratory Datamart, there were two influenza (1 influenza A(H3) and 1 influenza A(unknown subtype)) detections in week 42. Rhinovirus activity remains high but has decreased.

The overall number of acute respiratory infection incidents reported to PHE Health Protection Teams have decreased slightly from 1140 in the previous week to 1125 in week 42 in England. In the majority of these incidents SARS-CoV-2 has been detected. Educational settings still account for the highest proportion of reported incidents. Increases were seen in incidents reported in hospitals and other settings.

The majority of community and syndromic indicators decreased or remained stable during week 42. General practice (GP) influenza-like illness (ILI) consultations remained low in all UK schemes.

Through the UK GP swabbing scheme, SARS-CoV-2 positivity among patients contacting their GP with influenza like illness or lower respiratory tract infection symptoms increased from 5.5% in week 41 to 8.1% in week 42.

The overall COVID-19 confirmed hospital and ICU/HDU admission rates continued to increase whilst the influenza confirmed hospital and ICU/HDU admission rates remained low.

Emergency department attendances for COVID-19 like diagnosis have increased further in week 42 whilst those for acute respiratory infections remained stable.

The number of COVID-19 confirmed deaths increased further but no excess all-cause mortality was observed.
Overall estimated national seroprevalence based on blood donor samples was 5.7% with the highest seroprevalence by region seen in London and by age group in young adults.

Influenza vaccine uptake is the highest it has ever been at this point in the season for those aged 65+ and in 2 and 3 year olds, and for those in at-risk groups and pregnant women is slightly higher compared to last year.

Laboratory surveillance

Confirmed COVID-19 cases (England)

As of 09:00 on 20 October 2020, a total of 647,025 have been confirmed positive for COVID-19 in England under Pillar 1 and 2.

Overall case numbers and positivity remained high but were stable in both Pillar 1 and 2, in week 42, with the majority of cases reported from Pillar 2. The highest case rates and positivity were seen in the 10 to 19 and 20 to 29 year olds in both Pillar 1 and 2 although a decline is noted in these age groups and increases are noted across most of the other age groups. Cases rates and positivity continue to be highest in the North of England declines in positivity in some areas including the North East and East Midlands.

From this report onwards, case rates in Figures 3, 4, 7 and 9 have been calculated using mid-2019 ONS population estimates

*Figure 1: Laboratory confirmed COVID-19 cases tested under Pillar 1 and Pillar 2, based on sample week with overall weekly positivity for Pillar 1 and 2 (%)*

*The data are shown by the week the specimen was taken from the person being tested. This gives the most accurate analysis of this time progression, however, for the most recent week results for more samples are expected therefore this should be interpreted with caution.*
*Positivity data was previously deduplicated across the course of the pandemic to prevent persistent infections being counted as new cases. Since week 40, positivity is calculated as the number of individuals testing positive during the week divided by the number of individuals tested during the week. This approach accounts for the increasing number of individuals who will have been tested multiple times as the pandemic progresses.
Age and sex

Respiratory DataMart system (England)

The Respiratory Datamart system was initiated during the 2009 influenza pandemic to collate all laboratory testing information in England. It is now used as a sentinel laboratory surveillance tool, monitoring all major respiratory viruses in England. Laboratories in England will be reporting data for this season. As this is based on a sample of labs - SARS-CoV-2 positivity figures quoted here will differ from those quoted in the Confirmed COVID-19 cases section, however, they are included to facilitate comparison with data on other respiratory viruses.

In week 42 2020, out of the 77,841 respiratory specimens reported through the Respiratory DataMart System (based on data received from 12 out of 16 laboratories), 3,793 samples were positive for SARS-CoV-2 with an overall positivity of 4.9%. The highest positivity was noted in the 15 to 44 year olds at 6.7% in week 42. The overall influenza positivity was low at 0.3% in week 42, with two samples (1 influenza A(H3) and 1 influenza A(not subtyped)) testing positive (out of 655 tested) (Figure 11).

Rhinovirus positivity decreased slightly at 17.7% in week 42 compared to 18.6% in the previous week (Figure 12). The highest positivity by age group for rhinovirus was noted in the less than 5 year olds in week 42 (Figure 13). Respiratory syncytial virus (RSV), adenovirus, parainfluenza and human metapneumovirus (hMPV) positivity all remained low at 0.0%, 2.3%, 0.0% and 0.0% respectively in week 42 (Figure 12).

Proportion positive (%) over time for different age groups: 0 to 4 years, 5 to 14 years, 15 to 44 years, 45 to 64 years, and 65+ years.
Community surveillance

Acute respiratory infection incidents

Information on acute respiratory infection (ARI) incidents is based on situations reported to PHE Health Protection Teams (HPTs). These include:

- confirmed outbreaks of acute respiratory infections ie two or more laboratory confirmed cases (SARS-CoV-2, influenza or other respiratory pathogens) linked to a particular setting
- setting situations where an outbreak is suspected

All suspected outbreaks are further investigated by the HPT in liaison with local partners and a significant proportion do not meet the criteria of a confirmed outbreak. For example if suspected cases test negative for COVID19 or other respiratory pathogens, or cases are subsequently found not to have direct links to the setting. Since Pillar 2 testing became open to everyone during week 21 more incidents of mild disease have been detected in settings with healthy young populations.

Processes for reporting ARI incidents vary between PHE Centres. The denominator (the overall number of settings in each category) will differ by the setting category, for example there are fewer hospitals than workplaces, as will the propensity to report incidents to PHE. Therefore these data are more useful for monitoring trends over time than making comparisons across setting categories.

The number of incidents in each setting with at least one laboratory confirmed case of COVID19 are reported below. A national school helpline started operating on 17 September 2020 and a Universities helpline started operating on 7 October. This is likely to have had an impact on the number of situations/outbreaks being reported to HPTs in these settings

1202 new ARI incidents have been reported in week 42 in the UK (Figure 14):

- 311 incidents were from care homes where 210 had at least one linked case that tested positive for SARS-CoV-2
- 75 incidents were from hospitals where 60 had at least one linked case that tested positive for SARS-CoV-2
- 327 incidents were from educational settings where 252 had at least one linked case that tested positive for SARS-CoV-2
- 9 incidents were from prisons where 7 had at least one linked case that tested positive for SARS-CoV-2
- 262 incidents were from workplace settings where 189 had at least one linked case that tested positive for SARS-CoV-2
- 33 incidents were from food outlet/restaurant settings where 26 had at least one linked case that tested positive for SARS-CoV-2
- 166 incidents were from the other settings category where 111 had at least one linked case that tested positive for SARS-CoV-2

COVID-19 cases by type of residence

Table 3 shows the proportion of confirmed COVID-19 cases according to their type of residence. Property classifications are derived from Ordnance Survey AddressBase and are matched to address details within the laboratory data. Properties are identified by unique property reference number (UPRN) and basic land property unit (BLPU). Cases with poor or no address data which failed the address matching and are classed as ‘undetermined’. No fixed abode and overseas addresses identified by recording in the laboratory data.

In week 42, the highest percentage of confirmed COVID-19 cases by type of residence was seen in residential dwelling (Table 3).

Medical Officers of Schools Association (MOSA) & PHE surveillance scheme

Boarding schools in England within the MOSA network are recruited each season to report various respiratory related illnesses including influenza like illnesses (ILI).

Data will be reported from week 45.

If you are a MOSA school and would like to participate in this scheme, please email mosa@phe.gov.uk for more information.
FluSurvey

An internet based surveillance system has been developed based on FluSurvey. FluSurvey is a web tool survey designed to monitor trends of influenza like illness (ILI) in the community using self-reported respiratory symptoms from registered participants. The platform has been adapted to capture respiratory symptoms, exposure risk and healthcare seeking behaviours among registered participants to contribute to national surveillance of COVID-19 activity.

A total of 3,546 participants completed the weekly COVID-19 surveillance survey in week 42, of which 134 (3.8%) reported fever or cough. The most commonly reported method of access to healthcare services continue to be through telephoning a GP practice in week 42 (Figure 23).

ILI data will be reported from week 45.

Figure 23: Rate of contact with different healthcare services among FluSurvey participants reporting fever or cough symptoms, England

![Figure 23: Rate of contact with different healthcare services among FluSurvey participants reporting fever or cough symptoms, England](image-url)
Google search queries

This is a web-based syndromic surveillance system which uses daily search query frequency statistics obtained from the Google Health Trends API [1]. This model focuses on search queries about COVID-19 symptoms as well as generic queries about “coronavirus” (e.g. “covid-19”). The search query frequency time series has been weighted based on symptom frequency as reported in other data sources. Frequency of searches for symptoms is compared with a baseline calculated from historical daily data.

During week 42, the overall and media-debiasing weighted Google search scores remained stable with an increase noted in the latter part of the week (Figure 24).

**Figure 24: Normalised Google search score for COVID-19 symptoms, with weighted score for media-debiasing and historical trend, England**
The NHS 111 service monitors daily trends in phone calls made to the service in England, to capture trends in infectious diseases such as influenza and norovirus.

Up to 18 October 2020, the daily percentage of NHS 111 ‘potential COVID-19-like’ calls (as a percentage of total NHS 111 calls) remained stable whereas the number of online assessments are decreased slightly. The daily percentage of cold/flu calls (as a percentage of total NHS 111 calls) and cold/flu completed online assessments decreased (Figure 25 and 26). The daily percentage of loss of taste or smell calls decreased while online assessments for loss of taste or smell remained stable.

Please note that NHS 111 callers (from 11 May 2020) and NHS 111 online users (from 11 June 2020), who are assessed as having probable COVID-19 symptoms are now triaged using symptom specific pathways e.g. cold/flu, which are included in routine syndromic indicators.

Further information about these caveats is available from the PHE Remote Health Advice Syndromic Surveillance bulletin.

Figure 25: NHS 111 telephony indicators (and 7-day moving average) for (a) daily potential COVID-19 calls, (b) daily cold/flu calls and (c) daily loss of taste or smell calls, as a percentage of total calls for all ages, England

(c)
Primary care surveillance

RCGP (England)

The weekly ILI consultation rate through the RCGP surveillance was 1.8 per 100,000 registered population in participating GP practices in week 42 compared to the 1.7 per 100,000 in the previous week. This is below the baseline threshold (12.2 per 100,000) (Figure 27). By age group, the highest rates were seen in the 45 to 64 year olds (3.0 per 100,000) and in the 15 to 44 year olds (1.8 per 100,000). The Lower Respiratory Tract Infections (LRTI) consultation rate was at 22.1 per 100,000 in week 42, which was similar to the rate of 23.4 per 100,000 from the previous week. The COVID-19-like indicator consultation rate increased at 63.5 per 100,000 in week 42 compared to 72.7 per 100,000 in the previous week (Figure 28).

Figure 27: RCGP ILI consultation rates, all ages, England
Figure 28: RCGP ILI, LRTI and COVID-19-like indicator consultation rates, England
Overall, weekly ILI consultations rates were below baseline levels in Scotland, Northern Ireland and Wales in week 42 (Table 4).

By age group, the highest rates were seen in the 45 to 64 year olds in Scotland (1.0 per 100,000), in the 65 to 74 year olds in Wales (4.3 per 100,000) and in the 15 to 44 year olds in Northern Ireland (3.1 per 100,000).

**Table 4: GP ILI consultations in the UK for all ages with MEM thresholds applied**

| GP ILI consultation rates (all ages) | 40 | 41 | 42 | 43 | 44 | 45 | 46 | 47 | 48 | 49 | 50 | 51 | 52 | 1  | 2  | 3  | 4  |

| Wales                                | 1.0| 1.0| 1.0|    |    |    |    |    |    |    |    |    |    |    |    |    |
| Scotland                             | 0.5| 0.7| 0.5|    |    |    |    |    |    |    |    |    |    |    |    |    |
| Northern Ireland                     | 1.3| 1.5| 2.2|    |    |    |    |    |    |    |    |    |    |    |    |    |

The Moving Epidemic Method (MEM) has been adopted by the European Centre for Disease Prevention and Control to calculate thresholds for GP ILI consultations for the start of influenza activity (based on 10 seasons excluding 2009/10), in a standardised approach across Europe. For MEM threshold values for each country, please visit: https://www.gov.uk/guidance/sources-of-uk-flu-data-influenza-surveillance-in-the-uk#clinical-surveillance-through-primary-care
GP In Hours, Syndromic Surveillance

The GP In Hours (GPIH) syndromic surveillance system monitors the number of GP visits during regular hours of known clinical indicators.

Up to 18 October 2020, GPIH consultations for potential COVID-19-like consultations and ILI consultations remained stable (Figure 29). Please note that the GPIH COVID-19-like indicator presented in this report is derived from a reduced denominator population, compared to ILI.

Please note GP data should be interpreted with caution due to changes in advice regarding accessing GP surgeries due to COVID-19. Further information about these caveats is available from the PHE GP In Hours Syndromic Surveillance bulletin.

Figure 29: GPIH clinical indicators for (a) potential COVID-19 GP consultations and (b) influenza-like illness GP consultations, England

(a)
GP Out of Hours, Syndromic Surveillance

The GP Out of Hours (GPOOH) syndromic surveillance system monitors the numbers of daily unscheduled visits and calls to GPs during evenings, overnight, on weekends and on public holidays. Both systems cover around 55% of England’s population.

Up to 18 October 2020, GP out-of-hours and unscheduled care consultations for acute respiratory infections, influenza-like illness and difficulty breathing/asthma/wheeze remained stable (Figure 30).

![Graph](image)
Sentinel swabbing scheme in England and the Devolved Administrations

In week 42 2020, 11 samples tested positive for SARS-CoV-2 with an overall positivity of 8.1% (11/135) compared to 5.5% (10/181) in the previous week, through the UK GP sentinel swabbing schemes (Figure 31).

Samples up to week 41 were only tested for SARS-CoV-2.

*For the most recent week, more samples are expected to be tested therefore the graph in Figure 31 should be interpreted with caution

*Positivity (%) is not calculated when the total number tested is less than 10
Secondary care surveillance

SARI Watch

The Severe Acute Respiratory Infection (SARI) Watch surveillance system was established in 2020 to report the number of laboratory confirmed influenza and COVID-19 cases admitted to hospital and critical care units (ICU/HDU) in NHS acute trusts across England. This has replaced the USISS Mandatory and Sentinel data collections for influenza surveillance used in previous seasons, and the COVID-19 hospitalisations in England surveillance system (CHESS) collections for COVID-19 surveillance.

The weekly rate of new admissions of COVID-19 and influenza cases is based on the trust catchment population of those NHS Trusts who made a new return. This may differ from other published figures such as the total number of people currently in hospital with COVID-19.

Trends in hospital and critical care admission rates need to be interpreted in the context of testing recommendations.
Hospitalisations, SARI Watch

In week 42, the weekly hospital admission rate for COVID-19 increased further whilst the hospital admission rate for influenza was low.

The hospitalisation rate for COVID-19 was at 7.74 per 100,000 in week 42 compared to 5.55 per 100,000 in the previous week. The hospitalisation rate for influenza was at 0.02 per 100,000 in week 42 compared to 0.03 per 100,000 in the previous week; and there were two new confirmed influenza (one influenza A(H1N1)pdm09 and one influenza B) hospital admissions reported.

By NHS regions, the highest hospital admission rate for COVID-19 and influenza were observed in the North West. By age groups, the highest hospital admission rate for confirmed COVID-19 and influenza were in the 85+ year olds and in the 5 to 14 year olds respectively.

![Weekly overall hospital admission rates per 100,000 of new COVID-19 and influenza positive cases reported through SARI Watch, England](image)

* influenza hospital admission rate is reported from week 40 2020 onwards
* influenza hospital admission rate based on 26 sentinel NHS trusts for week 42

(b)
ICU/HDU admissions, SARI Watch

In week 42, the weekly ICU/HDU admission rates for COVID-19 increased further whilst the ICU/HDU admission rate for influenza was low.

The ICU/HDU rate for COVID-19 was at 0.59 per 100,000 in week 42 (based on data reported from 110 NHS Trusts) compared to 0.47 per 100,000 in the previous week. The ICU/HDU rate for influenza was at 0.00 per 100,000 in week 42 (based on data reported from 110 NHS Trusts) and there were two influenza (2 influenza A(unknown subtype)) confirmed ICU/HDU admissions.

By NHS regions, the highest ICU/HDU admission rates for COVID-19 and influenza were observed in the North West. By age groups, the highest ICU/HDU admission rates for COVID-19 and influenza were observed in the 65 to 74 year olds and in the 0 to 4 year olds respectively.

Figure 37: Weekly overall ICU/HDU admission rates per 100,000 of new COVID-19 and influenza positive cases reported through SARI Watch, England

(b)
ECMO, SARI Watch

Between 3 March and 20 October 2020, a total of 233 laboratory confirmed COVID-19 admissions have been reported from the 5 SRFs in England. There were two new laboratory confirmed COVID-19 admission reported in week 42 (Figure 42).

**Figure 42: Laboratory confirmed ECMO admissions (COVID-19, influenza and non-COVID-19 confirmed) to Severe Respiratory Failure centres in England**
Emergency Department attendances, Syndromic surveillance

The Emergency Department Syndromic Surveillance System (EDSSS) monitors the daily visits in a network of emergency departments across England.

Up to 18 October 2020, the daily number of ED attendances for all ages as reported by 69 EDs, for COVID-19-like attendances increased while attendances for acute respiratory infections remained stable (Figure 43).

Please note: the COVID-19-like ED indicator is an underestimation of the number of COVID-19 attendances as it only includes attendances with a COVID-19-like diagnosis as their primary diagnosis. The EDSSS COVID-19-like indicator should therefore be used to monitor trends in ED attendances and not to estimate actual numbers of COVID-19 ED attendances. Further information about these caveats is available from the PHE Emergency Department Syndromic Surveillance bulletin.

Mortality surveillance

Cumulative COVID-19 deaths

Changes to the definitions of COVID-19 related deaths in England are described in more detail in an accompanying PHE technical summary.

The current definitions used for mortality surveillance of COVID-19 in England are:

(a) 28 day definition: A death in a person with a laboratory-confirmed positive COVID-19 test and died within (equal to or less than) 28 days of the first positive specimen date
(b) 60 day definition: A death in a person with a laboratory-confirmed positive COVID-19 test and either: died within 60 days of the first specimen date OR died more than 60 days after the first specimen date only if COVID-19 is mentioned on the death certificate

The introduction of these definitions will affect the numbers which have been presented in past reports and therefore Figure 44 represents these differences by definition.

(a)
Figure 46 has been calculated using mid-2019 ONS population estimates.
Daily excess all-cause mortality (England)

Deaths occurring from 1 January to 14 October 2020 were assessed to calculate the daily excess above a baseline using age-group and region specific all cause deaths as provided daily by the General Register Office (GRO). The deaths were corrected to allow for delay to registration based on past data on these delays and the baseline was from the same day of the year in the previous 5 years +/- 7 days with an extrapolated time trend, and with 2 and 3 standard deviation (SD) limits shown (Figure 47).

Weeks in which at least 2 days exceeded the 3SD threshold are shown in Table 7 and the daily difference from the baseline by age and region is given in Figure 47. Note that as these data are by date of death with delay corrections, numbers are subject to change each week, particularly for more recent days.

No significant excess all-cause mortality was observed in week 40 overall, by age group or subnationally. The excess noted in week 33 coincides with a heat wave (Figure 47, 48 and Table 7).

(b)
Microbiological surveillance

Virus characterisation

PHE characterises the properties of influenza viruses through one or more tests, including genome sequencing (genetic analysis) and haemagglutination inhibition (HI) assays (antigenic analysis). These data are used to compare how similar the currently circulating influenza viruses are to the strains included in seasonal influenza vaccines, and to monitor for changes in circulating influenza viruses. The interpretation of genetic and antigenic data sources is complex due to a number of factors, for example, not all viruses can be cultivated in sufficient quantity for antigenic characterisation, so that viruses with sequence information may not be able to be antigenically characterised as well. Occasionally, this can lead to a biased view of the properties of circulating viruses, as the viruses which can be recovered and analysed antigenically, may not be fully representative of majority variants, and genetic characterisation data does not always predict the antigenic characterisation.

In week 42, no influenza viruses were characterised by PHE Respiratory Virus Unit (RVU).

Antiviral susceptibility

Influenza positive samples are screened for mutations in the virus neuraminidase gene known to confer oseltamivir and/or zanamivir resistance. Additionally, testing of influenza A(H1N1)pdm09, A(H3N2), and influenza B virus isolates for neuraminidase inhibitor susceptibility (oseltamivir and zanamivir) is performed at PHE-RVU using a functional assay. The data summarized below combine the results of both testing methods. The samples tested are routinely obtained for surveillance purposes, but diagnostic testing of patients suspected to be infected with neuraminidase inhibitor-resistant virus is also performed.

In week 42, no influenza viruses were tested for antiviral susceptibility.
Antimicrobial susceptibility

Table 8 shows in the 12 weeks up to week 40 2020, the proportion of all lower respiratory tract isolates of Streptococcus pneumoniae, Haemophilus influenza, Staphylococcus aureus, MRSA and MSSA tested and susceptible to antibiotics. These organisms are the key causes of community-acquired pneumonia (CAP) and the choice of antibiotics reflects the British Thoracic Society empirical guidelines for management of CAP in adults.

* Macrolides = erythromycin, azithromycin and clarithromycin

Data source: PHE’s SGSS CDR module. Please note that this is different to the data source used during the 2019/20 influenza season when the SGSS AMR module was used, and so the results are not directly comparable.
There has been a reduction in the total number of bacterial positive lower respiratory tract clinical samples reported to PHE since mid-March 2020.
COVID-19 sero-prevalence surveillance

In this week’s report the results from testing samples provided by healthy adult blood donors aged 17 years and older, supplied by the NHS Blood and Transplant (NHS BT collection) between weeks 17 -41 are summarised. Donor samples from two different geographic regions (approximately 1000 samples per region) in England are tested each week. Since week 26, an exclusion of donors aged 70 years and older donating throughout lockdown was lifted, and therefore data since then include donors in this older age group.

Seroprevalence in Adults aged 17 years and older (Blood Donors)

The results presented here are based on testing using the Euroimmun assay for blood donor samples collected between weeks 17-41. This week’s report includes the results of testing the 14th set of samples from London (week 41) and the 7th set of samples from the South West (week 41).

This report presents seropositivity estimates using a 4-week rolling prevalence for national and regional estimates. Seroprevalence estimates reported are based on seropositivity which are unadjusted for the sensitivity and specificity of the assays used. This is because assay sensitivity will change according to the time since infection in these cohorts due to waning of antibodies.

National Prevalence

Overall population weighted (by age group, sex and NHS region) antibody prevalence using the Euroimmun assay among blood donors aged 17 years and older in England was 5.7% (95% CI 5.1% - 6.2%) for the period 16th September– 11th October (weeks 38-41). Estimates are based on 7978 samples, of which 484 were positive. This compares with 5.9% (95% CI 5.4%-6.5%) for the period of 9th September – 4th October (weeks 37-40). Changes in prevalence over time need to take into account demographic changes in the donor population, with later data including donors aged 70 years and older who were previously excluded from donating during lockdown. Waning immunity is also likely to be a contributing factor.

Regional Prevalence over Time

Seropositivity (weighted by age group and sex) vary across the country and over time. Figure 49 shows the overall 4-weekly rolling proportion seropositive in each region over time. Seropositivity estimates are plotted on the mid-point of the 4-weekly period.

In London where estimates have consistently been highest, the 4-weekly rolling seropositivity increased from 11.9% (week 16-19) to 13.7% (weeks 20-23). From week 24, seropositivity declined and plateaued with estimates at 7.8% in weeks 30-33. This was then followed by a rise in seropositivity to 10.4% (95% CI 9.1% - 12%) in weeks 34-37 and a recent slight decline to 8.8% (95% CI 7.6% - 10.1%) in weeks 38-41.
Contributory factors to this fluctuation are likely to include variability in the precise locations of sampling within London and changes in exposure of donors. Increases in seropositivity observed in weeks 34-37 in part may reflect samples being tested from donors who were likely to be returning to donate having donated in earlier parts of the epidemic when incidence was high.

Seropositivity in the South West region was 3.3% (95% CI 2.3 – 4.5%) in (weeks 38-41) lower than the 4.1% (95% CI 2.9% - 5.8%) observed in the previous survey in weeks 37-40.

In the North East and Yorkshire NHS region the seropositivity has increased to 5.6% (95% CI 4.3%-7.3%) in weeks 37-40 compared with 3.7% (95% CI 2.7%-5.0%) in week 36-39.

Data from the Midlands also show a higher proportion seropositive at 6.5% (95% CI 5.0%-8.4%) in weeks 37-40. This compares to 5.5% (95% CI 4.3%-7.0%) in weeks 36-39.

Data from the North West show that seropositivity was 5.9% (95% CI 4.4% - 7.9%) in weeks 34-37 and more recently 5.3% in weeks 37-40 (95% CI 4.1-6.9%) showing a continued plateauing.

In the East of England seropositivity was 5.9% (95% CI 4.3% - 7.9%) in the most recent data (weeks 38-41) fluctuating between 4.1% (95% CI 3.0% - 5.7%) in weeks 32-35 and 5.9% (95% CI 4.6% - 7.6%) in weeks 35-38.

Seropositivity in the South East region was 3.2% (95% CI 2.2% - 4.7%) in the latest data (weeks 38-41) lower than the 5.1% (95% CI 3.3% - 7.7%) observed in weeks 33-36.

The change in proportion seropositive observed in some regions is likely to be largely driven by changes in the precise locations of sample collection. However, the most recent increases observed in the Midlands and North East regions cannot be fully explained by this and are likely to reflect increased transmission, consistent with other surveillance data. Increases in seropositivity reflect transmission occurring at least two to three weeks previously given the time taken to generate an antibody response following infection. Declines in prevalence observed during the summer months can be partially explained by demographic differences in the donor population as lockdown measures were relaxed. Examples include a reduction in attendance of regular donors in August and that donors aged 70 years and above were not allowed to donate during lockdown, but this exclusion was lifted from week 26. Waning immunity will also be a contributing factor to the lower prevalence.
Prevalence by age group

Population weighted antibody prevalence (unadjusted) estimates have generally remained highest in donors aged 17-29 and decline with age, with lowest prevalence in donors aged 70-84. Donors aged 70-84 years are only included from week 26 onward as this age group, who were advised to shield during lockdown, have been able to return to donor clinics since then (Figure 50).

The largest variation over time are observed in those aged 17-29, prevalence has decreased from 10.8% (95% CI 9.0%-12.9%) in weeks 19-22 to 8.4% (95% CI 6.9.1%-10.2%) in weeks 38-41. Recently the prevalence in 70-84 year olds has fluctuated from 2.9% (95% CI 1.8%-4.5%) in week 36-39 to 3.2% (95% CI 1.9%-5.3%) in week 38-41.

**Figure 49**: 4-weekly rolling SARS-CoV-2 antibody seroprevalence (% seropositive) in blood donors by region, using Euroimmun test; error bars show 95% confidence intervals
Figure 50: Population weighted 4-weekly rolling SARS-CoV-2 antibody seroprevalence (% seropositive) in blood donors by age group, using Euroimmun test; error bars show 95% confidence intervals.
Influenza vaccination

Influenza vaccine uptake in GP patients

Up to week 42 2020 in 90.3% of GP practices reporting weekly to Immform for the main collection, the provisional proportion of people in England who had received the 2020/21 influenza vaccine in targeted groups was as follows (Figure 51):

- 16.4% in under 65 years in a clinical risk group
- 18.0% in pregnant women
- 57.2% in 65+ year olds

**Figure 51: Cumulative weekly influenza vaccine uptake by target group in England**

In 2020/21, all 2 and 3 year olds continue to be eligible for influenza vaccination through their GPs. Up to week 42 2020, in 97.5% of GP practices reporting weekly to Immform for the childhood collection, the provisional proportion of children in England who had received the 2020/21 influenza vaccine in targeted groups was as follows (Figure 52):

- 26.0% in 2 year olds
- 27.4% in 3 year olds
Figure 52: Cumulative weekly influenza vaccine uptake in 2 and 3 year olds, in England

2020/21 season indicated by bold lines, 2019/20 season indicated by fainter lines.
Influenza vaccine uptake in school age children

The first report on influenza vaccine uptake in school age children (Year Reception to Year 7) will be published in November 2020.

Influenza vaccine uptake in healthcare workers

The first report on influenza vaccine uptake in healthcare workers will be published in November 2020.
International update

Global COVID-19 update

Globally, up to 20 October 2020, a total of 40,546,955 cases of COVID-19 infection have been reported worldwide, including 1,120,526 COVID-19 related deaths.

For further information on the global COVID-19 situation please see the WHO COVID-19 situation reports.

Figure 53: Global map of cumulative COVID-19 cases
Figure 54: Global map of weekly COVID-19 case incidence rate per 100,000, week 42 2020
Global influenza update

Updated on 13 October 2020 (based on data up to 29 September 2020) (WHO website)

In the temperate zone of the northern hemisphere, influenza activity remained below inter-seasonal levels. In the temperate zones of the southern hemisphere, the influenza season remained low or below baseline. Worldwide, of the very low numbers of detections reported, seasonal influenza A(H3N2) viruses accounted for the majority of detections.

In the countries of North America, influenza activity indicators, including the percent of tests positive for influenza, were at very low levels.

In Europe, influenza activity remained at inter-seasonal levels though sporadic detections were reported across reporting countries.

In Central Asia and Northern Africa, there were no influenza updates for this reporting period.

In Western Asia, there were no influenza detections and ILI levels were low across reporting countries.

In East Asia, influenza illness indicators and influenza activity remained at inter-seasonal levels in most reporting countries

In the Caribbean and Central American countries, there were no influenza detections reported.

In tropical South America, tropical Africa and Southern Asia there were sporadic or no influenza detections across reporting countries.

In South East Asia, increased influenza detections were reported in Cambodia and Lao People's Democratic Republic (PDR).

In Oceania, influenza like illness (ILI) and other influenza activity indicators remained below usual levels for this time of year in general.

The WHO GISRS laboratories tested more than 50521 specimens between 14 September 2020 and 27 September 2020. 99 were positive for influenza viruses, of which 60 (60.6%) were typed as influenza A and 39 (39.4%) as influenza B. Of the sub-typed influenza A viruses, 50 (100%) were influenza A (H3N2). Of the characterized B viruses, 5 (22.7%) belonged to the B-Yamagata lineage and 17 (77.3%) to the B-Victoria lineage.
Influenza in Europe
Updated on 16 October 2020 (Joint ECDC-WHO Europe Influenza weekly update)

For week 41 2020, influenza activity remained at interseasonal levels throughout Europe.

Of 26 countries and areas that reported on the intensity indicator, 23 reported activity at baseline levels, 2 reported low intensity (Azerbaijan and Slovakia), and 1 reported medium intensity (Denmark) for week 41/2020. Of 27 countries and areas that reported on geographic spread, 24 reported no activity and 3 reported sporadic spread (Denmark, United Kingdom (Scotland) and Slovakia) for week 41/2020.

For week 41/2020, of 107 sentinel specimens tested for influenza viruses, none were positive.

There were no hospitalised laboratory-confirmed influenza cases in ICUs for week 41/2020.

There were no laboratory-confirmed influenza cases in wards outside ICUs for week 41/2020.

Influenza in the Northern Hemisphere

Influenza activity remains low in the United States of America and in Canada.

For further information on influenza in the United States of America please see the Centre for Disease Control weekly influenza surveillance report.

For further information on influenza in Canada please see the Public Health Agency weekly influenza report.
Other respiratory viruses

Avian influenza

Latest update on 10 July 2020 (WHO website)

Influenza A(H5) viruses:
According to reports received by the World Organisation for Animal Health (OIE), various influenza A(H5) subtypes continue to be detected in birds in Africa, Europe and Asia.

Influenza A(H7N9) viruses:
There have been no publicly available reports from animal health authorities in China or other countries on influenza A(H7N9) virus detections in animals in recent months.

Influenza A(H9N2) viruses:
Between 9 May and 10 July 2020 two new laboratory-confirmed human cases of influenza A(H9N2) virus infections were reported from China.

Middle East respiratory syndrome coronavirus (MERS-CoV)

Latest update on 20 October 2020 (WHO website)

Up to 20 October 2020, a total of five cases of Middle East respiratory syndrome coronavirus, MERS-CoV, (three imported and two linked cases) have been confirmed in the UK. On-going surveillance has identified 1,816 suspected cases in the UK since September 2012 that have been investigated for MERS-CoV and tested negative.

From 1 April to 31 May 2020, the National IHR Focal Point of Saudi Arabia reported 9 new cases of MERS-CoV infection, including five deaths.

Globally, since September 2012, WHO has been notified of 2,562 laboratory-confirmed cases of infection with MERS-CoV, including 881 related deaths. Further information on management and guidance of possible cases is available online. The latest ECDC MERS-CoV risk assessment can be found here, where it is highlighted that risk of widespread transmission of MERS-CoV remains very low.
