Appendix J – Asbestos Assessment

Asbestos

Asbestos exposure principally occurs when dry material containing asbestos is disturbed such that asbestos fibres are released into the air and the airborne fibres are breathed in. There are various estimates for airborne dust concentrations that can arise from wind blowing across the ground surface, and that can arise from more localised physical disturbance of soil. The Environment Agency's CLEA methodology (Environment Agency, 2009) identifies a range of average outdoor ambient air dust concentrations for different land-uses, based on land cover and land area. The authors of CIRIA C733 (Nathanail, et al., 2014) proposed a reasonable worst-case localised airborne dust concentration resulting from activity such as gardening (but also applicable to children playing with soil). These estimates are summarised in the table below.

Estimates for Ambient Air Dust Concentrations

Scenario/land-use	Ambient Air Dust Concentration (PM10)
Residential land-use	0.4 µg/m^3
Commercial land-use	12 µg/m^3
Public open space in residential areas	4 µg/m^3
Public open space - parks	8.5 µg/m^3
Gardening	100 µg/m^3

A cautious estimate of the potential airborne asbestos concentration associated with such dust levels can be made using laboratory research published by the Institute of Occupational Medicine (Addison, et al., 1988). The average normalised airborne asbestos fibre to dust concentration in the dust experiments were:

- For asbestos in soil concentrations of 0.001%wt/wt:

  0.01 f/ml asbestos per mg/m^3 dust for chrysotile (values ranged from 0.01-0.02 between different soil types).

  0.03 f/ml asbestos per mg/m^3 for amosite (values ranged from 0.01-0.04 between different soil types).

- For asbestos in soil concentrations of 0.01%wt/wt:

  0.04 f/ml asbestos per mg/m^3 dust for chrysotile (values ranged from 0.02-0.06 between different soil types).

  0.07 f/ml asbestos per mg/m^3 for amosite (values ranged from 0.02-0.15 between different soil types).

Crocidolite fibres have been detected in a small number of samples alongside fibres of chrysotile and/or amosite, and it is expected that the crocidolite is present as a result of being a minor constituent or cross-contaminant of the original asbestos containing material (ACM). Consequently, the reported asbestos concentrations in the samples are interpreted to be indicative of the chrysotile or amosite concentration and not that of crocidolite. Calculations for crocidolite have not been done on this basis.

Taking the residential land-use ambient dust concentration of 0.4µg/m^3 and the localised dust concentration of 100µg/m^3 for gardening/playing, cautious estimates of airborne asbestos concentrations can be made as follows the table below.

Cautious estimates of asbestos ambient air concentrations

Soil Concentration	Residential land-use	Gardening/Playing	Comparison with Dutch Study (Swartjes & Tromp, 2008) Estimates$^+$
Chrysotile 0.001%wt/wt	0.000004f/ml	0.001f/ml	0.000015-0.00035f/ml
Amosite 0.001%wt/wt	0.000012f/ml	0.003f/ml	0.000015-0.00035f/ml
Chrysotile 0.01% wt/wt	0.000016f/ml	0.004f/ml	0.0001-0.0015f/ml
Amosite 0.01%wt/wt	0.000028f/ml	0.007f/ml	0.0001-0.0015f/ml

[+] These estimates are based on different laboratory experiments and field monitoring of activities that are different to those based on the CLEA/CIRIA/IOM data. SoBRA has published a calculation tool (Cole, et al., 2021) that can be used to calculate risk estimates based on predicted or measured ambient air concentrations and this tool has been used to perform the calculations detailed below. In addition to the ambient air concentration, the tool requires the age of the people breathing in the air, and the hours per day, days per year, and number of years those people might breathe in that air.

The CIRIA garden dust estimate is based on very dry soil conditions and the authors of that guidance provide an example based on a previous investigation in the UK that very dry conditions might persist for on average 90 days per year, noting that UK summer weather is characteristically variable year on year. This is considered to be a reasonable assumption on that basis – noting that days of very dry and dusty conditions are not the same as days without rain. For the CLEA residential area average it is appropriate to conservatively assume 365 days per year. The SoBRA model reports are appended and the risk estimates (likelihood of developing and dying of asbestos disease) are summarised in the table below.

Health Risk Estimates

Scenario	Risk for chrysotile at 0.001%wt/wt in soil	Risk for chrysotile at 0.01%wt/wt in soil	Risk for amosite at 0.001%wt/wt in soil	Risk for amosite at 0.01%wt/wt in soil
Gardening/playing – exposure for 6 years[1] as a young child	1.3×10^{-8}	5.12×10^{-8}	3.9×10^{-6}	9.0×10^{-6}
Gardening/playing - exposure through adulthood	1.4×10^{-8}	5.9×10^{-8}	4.0×10^{-6}	9.6×10^{-6}
Ambient air exposure – 6 years continuous exposure as a young child	5.1×10^{-11}	2.0×10^{-10}	1.5×10^{-8}	3.6×10^{-8}
Ambient air exposure – through adulthood	2.0×10^{-10}	8.1×10^{-10}	5.9×10^{-8}	1.4×10^{-7}

Note: 1×10^{-6} is a one in a million risk, 1×10^{-8} is a one in a billion risk

In summary, as noted in **Section 6.7, Table 20**, nine reported concentrations of asbestos in soil equalled or exceeded the GSC (Dutch Tier 2 values). No reported concentrations exceed 0.01%wt/wt for dispersed loose fibres (the form of asbestos soil contamination assessed by Addison et al). Average soil concentrations of asbestos are therefore expected to pose a very low risk to health from ambient airborne exposure. Ad hoc higher exposure (such as from gardening or playing) is similarly expected to pose a low to very low risk to health - with exposure to chrysotile posing a lower risk than to amosite. Although typical background concentrations are not available, asbestos is known to be present in urban soils and there is no robust evidence that the range of concentrations identified in the soil samples is specifically higher than typical urban conditions. The highest reported soil concentrations are from samples taken beneath areas of turf, and very low levels of fibre bundles have been detected in soil samples from raised beds where periodic soil replenishment is undertaken. Whilst the deposition of dust and debris from the fire is less likely to be the cause of the higher concentrations detected beneath areas of turf, it cannot be ruled out that the very low concentrations detected in raised beds may in part be the result of the fire.

[1] 6 years exposure from birth is considered the critical (most sensitive) period of exposure in the CLEA methodology

Top 2 applied? No

Where top 2 method is applied, two produce categories use 90th percentile rates, while the remainder use the mean. Produce categories vary on a chemical-by-chemical basis. Where top 2 method is not used, all produce categories for all chemicals assume 90th percentile rates.

Top 2 applied? No

Where top 2 method is applied, two produce categories use 90th percentile rates, while the remainder use the mean. Produce categories vary on a chemical-by-chemical basis. Where top 2 method is not used, all produce categories for all chemicals assume 90th percentile rates.

Derivation of Schools Generic Screening Criteria

This appendix sets out the derivation of the generic screening criteria (GSC) for schools that have been developed for lead and benzo(a)pyrene. The purpose of these GSC is to permit the reliable screening of soil concentration data attributable to soil samples taken from schools as part of the Stage 2 Investigation. Paragraph 3.30 of the Statutory Guidance for Part 2A permits the development of GSC to help assessors decide when land might be assumed to be in Category 4, i.e. decide when land can be excluded from the need for further inspection or assessment, and the GSC detailed below are designed specifically for this purpose. Existing published exposure model assumptions and parameter values have been used where possible, and reasonable (precautionary) assumptions have been made where land-use scenario-specific assumptions are required. These land-use scenario-specific assumptions are based on reasonable estimates rather than the extensive research undertaken by the Environment Agency in the development of the CLEA methodology (Environment Agency, 2009) and associated Soil Guideline Values, and that undertaken by the CL:AIRE consortium in the development of the Category 4 Screening Levels (CL:AIRE, 2014). The exposure assumptions and GSC set out below therefore do not constitute a definitive exposure model for schools but do constitute a set of assumptions and GSC that are protective of human health consistent with the definition of Category 4.

Exposure Model

The generic exposure pathways considered relevant to generic school land-use scenario are detailed below and are based on the generic pathways considered in the CLEA and C4SL methodologies. The generic land-use is designed to be relevant to primary schools and secondary schools/colleges, and therefore exposure assumptions have been selected that are protective of the most sensitive receptor (i.e. the youngest children attending primary school).

Table 1. Generic Exposure Pathways

Exposure Pathway	Include?	Reasoning
Direct ingestion of soil (outdoors) and dust derived from soil (indoors)	Yes	This is relevant to children playing outside in play areas and playing fields where there is bare soil or grassed cover as it is for playing in public open spaces and residential gardens, and it is reasonable to assume that tracked back soil into school buildings will apply as it does for residential and commercial buildings.
Ingestion of soil attached to fruit/vegetables	No	Growing beds are present at a number of the schools included in the Stage 2 Investigation. However, an individual child's consumption of produce grown in these locations is expected to be very minor in the context of their overall diet and there is no reliable data available to quantify this exposure in the model. Taking lead as an example, the C4SL for residential land-use is based on the assumption that a 4-5 yr old child consumes approximately 10kg of homegrown produce a year. The amount of produce grown at school that a child might eat in a year is expected to be substantially less than this such that the ad hoc consumption of such produce would not be expected to be of any concern and not reliably quantified. A check for the reasonableness of this assumption has been made in the main report by comparing the contaminant concentrations detected in produce samples from schools with those reported from allotments and community kitchen gardens.
Ingestion of fruit/vegetables	No	See above.
Dermal contact with dust derived from soil (indoors)	Yes	This is as relevant for children in school as it is for children at home in a residential setting when the assuming that soil from outside will be tracked back inside by children.
Dermal contact with soil (outdoors)	Yes	This is directly relevant to children playing outside in areas where there is bare soil or grass cover.
Inhalation of dust derived from soil (indoors)	Yes	This is as relevant for children in school as it is for children at home in a residential setting when the assuming that soil from outside will be tracked back inside by children.
Inhalation of dust derived from soil (outdoors)	Yes	This is directly relevant to children playing outside in areas where there is bare soil or grass cover.
Inhalation of vapours (indoors)	Yes	This is only relevant for volatile and semi-volatile contaminants when they are present (or assumed to be present) directly beneath (or in the proximity of) the footprint of the school buildings.

Exposure Pathway	Include?	Reasoning
Inhalation of vapours (outdoors)	Yes	This is only relevant for volatile and semi-volatile contaminants and where children play outside where there is no impermeable ground cover.

Table 2. CLEA Model Parameterisation

Model Parameter	Value	Reasoning
Land Use	School	N/A
Receptor	Female (residential C4SL)	Default for the derivation of SGV and C4SLs is a female child due to expected lower bodyweight. Physiological parameters used to define children for residential, allotment and public open space land uses equally applicable for schools.
Building	School	N/A (and of minimal relevance to non and low volatility contaminants.
Soil Type	Sandy Loam	Default selection for SGV and C4SLs.
Start Age Class	5 (age 4-5)	Expected starting age for primary school.
End Age Class	11 (age 10-11)	Expected finishing age for primary school. An alternative option is to stop at age class 10 to maintain the international practice for a child receptor of 6 years exposure duration.
Exposure Duration	7 years	A function of the choice of start and end age classes.
Soil pH	7	Default selection for SGV and C4SLs.
Soil Organic Matter Content	6%	Default selection for SGV and C4SLs.
Exposure Frequencies		
Soil and dust ingestion	195 days per year	Approximate number of days in a typical school year.
Consumption of homegrown produce	N/A	Refer to justification in Table 1.
Skin contact indoors	195 days per year	Approximate number of days in a typical school year.
Skin contact outdoors	195 days per year	Approximate number of days in a typical school year. Assumption that children will play outside every day regardless of weather.
Inhalation of dust and vapour indoors	195 days per year	Approximate number of days in a typical school year.
Inhalation of dust and vapour outdoors	195 days per year	Approximate number of days in a typical school year. Assumption that children will play outside every day regardless of weather.
Occupancy period indoors	8 hours per day	Assumption for extended school day that includes breakfast and after school clubs.
Occupancy period outdoors	2 hours per day	Assumption for the combination of mid-morning break, lunchtime, mid-afternoon break and/or some indeterminate time playing on school grounds immediately before and/or after school.
Soil to skin adherence factor indoors	0.06 mg per cm^2 per day	Value used for residential and public open space C4SLs and no reason to change.
Soil to skin adherence factor outdoors	0.1 mg per cm^2 per day	Value used for residential and public open space C4SLs and no reason to change.
Soil and dust ingestion rate	0.1 g per day	Value used for residential SGV and C4SLs. It is noted that the value used for public open space C4SLs is less (0.5-0.75 g per day). These lower values are based on the

Model Parameter	Value	Reasoning
		assumption that the ratio between the ingestion of soil and soil-derived dust is 50:50, so the ingestion rate for days with indoor exposure only is 50 mg per day.
Body weight	16.9-35.7 kg	Values for female children in the derivation of the C4SLs.
Body height	1.0-1.4 m	Values for female children in the derivation of the C4SLs.
Inhalation rate	10.1-12.0 m^3 per day	Values for female children in the derivation of the C4SLs.
Maximum exposed skin fraction indoors	0.22-0.35 m^2 per m^2	Values for female children in the derivation of the C4SLs.
Maximum exposed skin fraction outdoors	0.14-0.28 m^2 per m^2	Values for female children in the derivation of the C4SLs.
Building Properties		
Building footprint	100 m^2	Without a detailed inventory of school buildings an assumption of 10 m x 10 m has been used. As lead and benzo(a)pyrene are not volatile contaminants this is not a critical parameter value.
Living space air exchange rate	0.5 oer hour	Value used for residential C4SL. The value for commercial buildings is double (1.0). Residential value in the absence of information for school buildings. As lead and benzo(a)pyrene are not volatile contaminants this is not a critical parameter value.
Living space height (above ground)	2.4 m	Value used for a single storey building in the CLEA methodology. Single storey buildings are the most sensitive to vapour intrusion to the lower indoor air mixing volume.
Living space height (below ground)	0 m	Assumption that schools do not have occupied basements.
Pressure differential (soil to enclosed space)	2.6 Pa	The value used for single storey building in the CLEA methodology.
Foundation thickness	0.15 m	The value used in the derivation of SGV and C4SLs. Building foundation is assumed to be a ground bearing concrete slab.
Floor crack area	800 cm^2	Assumption of a 2 mm perimeter crack between floor and walls. This is the same assumption used in the derivation of SGV and C4SLs.
Dust loading factor	100 µg/m^3	Based on the suggestion from Dutch RIVM report 711701037/2004 that school classrooms are likely to be dustier than residential buildings.
Air dispersion model		
Mean annual windspeed	5 m per second	Value used in the derivation of SGV and C4SLs.
Air dispersion factor at height of 0.8 m	120 g per m^2 per second per kg per m^3	Value for a 0.5-hectare area stated in the CLEA methodology. School areas vary, the larger the area the greater the potential for dust generation. 0.5 hectares is considered to be a reasonable balance for the majority of primary schools.
Air dispersion factor at height of 1.6 m	280 g per m^2 per second per kg per m^3	Value for a 0.5-hectare area stated in the CLEA methodology.

Model Parameter	Value	Reasoning
Fraction of site with hard or vegetative cover	0.75	Value used in the derivation of SGV and C4SLs for both residential and public open space land-uses. No reason to alter this assumption for schools.
Vapour Model		
Use default soil gas ingress rate	No	Default rates are based on specific building assumptions that are not applicable to the chosen school building.
Depth to top of source (beneath building)	65 cm	Value used in the derivation of SGV and C4SLs.
Depth to top of source (no building)	0 cm	Value used in the derivation of SGV and C4SLs.
Time average period for surface emissions	7 years	Set as the exposure duration as per the approach taken in the derivation of SGV and C4SLs.
Effective air permeability of the soil	3.05 E-08 cm^2	CLEA model value for chosen soil type.

Toxicity and Physchem Parameters

All toxicity and physchem parameters adopted in the derivation of the GSC are those used in the derivation of the published C4SLs for these two contaminants. The details of these parameter values can be found in the appended CLEA model output reports and have not been repeated here.

Generic Screening Criteria

The GSC for lead and benzo(a)pyrene calculated using the CLEA model version 1.071 published by the Environment Agency in 2015 are detailed in Table 3 below:

Table 3. GSC

Contaminant	GSC
Lead	1050 mg/kg (based on all routes of exposure)
Benzo(a)pyrene	17 mg/kg (based on oral and dermal routes of exposure) 104 mg/kg (based on inhalation routes of exposure)

Because the derivation of the GSC has not been completed on the back of a detailed review of school-specific parameters the model scenario developed is not definitive and without question. It is plausible that further research could amend one or more of the parameter values that have been assigned here. However, the parameter values chosen have been chosen because they are considered to be reasonable and precautionary values that are relevant and appropriate to the assessment being made.

Top 2 applied? No

Where top 2 method is applied, two produce categories use 90th percentile rates, while the remainder use the mean. Produce categories vary on a chemical-by-chemical basis. Where top 2 method is not used, all produce categories for all chemicals assume 90th percentile rates.

Appendix J – CLEA Model for Plant Uptake of Lead at Treadgold House

CLEA Software Version 1.071

Report generated	23/04/2021
Report title	Treadgold House plant uptake of lead
Created by	AECOM

BASIC SETTINGS

Land Use	Residential with produce (C4SL)						
Building	Small terraced house						
Receptor	Female (res C4SL)	Start age class	1	End age class	6	Exposure Duration	6 years
Soil	Sandy loam						

Exposure Pathways

Direct soil and dust ingestion	✖	Dermal contact with indoor dust	✖	Inhalation of indoor dust	✖
Consumption of homegrown produce	✓	Dermal contact with soil	✖	Inhalation of soil dust	✖
Soil attached to homegrown produce	✓			Inhalation of indoor vapour	✖
				Inhalation of outdoor vapour	✖

Top 2 applied? Yes

Where top 2 method is applied, two produce categories use 90th percentile rates, while the remainder use the mean. Produce categories vary on a chemical-by-chemical basis. Where top 2 method is not used, all produce categories for all chemicals assume 90th percentile rates.

Top 2 applied? Yes

Where top 2 method is applied, two produce categories use 90th percentile rates, while the remainder use the mean. Produce categories vary on a chemical-by-chemical basis. Where top 2 method is not used, all produce categories for all chemicals assume 90th percentile rates.

Top 2 applied? Yes

Where top 2 method is applied, two produce categories use 90th percentile rates, while the remainder use the mean. Produce categories vary on a chemical-by-chemical basis. Where top 2 method is not used, all produce categories for all chemicals assume 90th percentile rates.

BASIC SETTINGS

Land Use	Residential with produce (C4SL)					
Building	Small terraced house					
Receptor	Female (res C4SL)	Start age class	1	End age class	6	Exposure Duration 6 years
Soil	Sandy loam					

Exposure Pathways

Direct soil and dust ingestion	✓	Dermal contact with indoor dust	✓	Inhalation of indoor dust	✓
Consumption of homegrown produce	✓	Dermal contact with soil	✓	Inhalation of soil dust	✓
Soil attached to homegrown produce	✓			Inhalation of indoor vapour	✓
				Inhalation of outdoor vapour	✓

Top 2 applied? Yes

Where top 2 method is applied, two produce categories use 90th percentile rates, while the remainder use the mean. Produce categories vary on a chemical-by-chemical basis. Where top 2 method is not used, all produce categories for all chemicals assume 90th percentile rates.

BASIC SETTINGS

Land Use	Public Open Space (res C4SL)						
Building	Small terraced house						
Receptor	Female (res C4SL)	Start age class	4	End age class	9	Exposure Duration	6 years
Soil	Sandy loam						

Exposure Pathways

Direct soil and dust ingestion	✓	Dermal contact with indoor dust	✓	Inhalation of indoor dust	✓
Consumption of homegrown produce	✖	Dermal contact with soil	✓	Inhalation of soil dust	✓
Soil attached to homegrown produce	✖			Inhalation of indoor vapour	✖
				Inhalation of outdoor vapour	✓

Top 2 applied? Yes

Where top 2 method is applied, two produce categories use 90th percentile rates, while the remainder use the mean. Produce categories vary on a chemical-by-chemical basis. Where top 2 method is not used, all produce categories for all chemicals assume 90th percentile rates.

BASIC SETTINGS

Land Use	Residential without produce (C4SL)					
Building	Small terraced house					
Receptor	Female (res C4SL)	Start age class	1	End age class	6	Exposure Duration 6 years
Soil	Sandy loam					

Exposure Pathways

Direct soil and dust ingestion	✓	Dermal contact with indoor dust	✓	Inhalation of indoor dust	✓
Consumption of homegrown produce	✖	Dermal contact with soil	✓	Inhalation of soil dust	✓
Soil attached to homegrown produce	✖			Inhalation of indoor vapour	✓
				Inhalation of outdoor vapour	✓

Top 2 applied? Yes

Where top 2 method is applied, two produce categories use 90th percentile rates, while the remainder use the mean. Produce categories vary on a chemical-by-chemical basis. Where top 2 method is not used, all produce categories for all chemicals assume 90th percentile rates.

CLEA Software Version 1.071

Report generated	26/05/2021
Report title	Grenfell Investigation into Potential Land Contamination Impacts
Created by	DJD at AECOM

BASIC SETTINGS

Land Use	Public Open Space (park C4SL)						
Building	No building						
Receptor	Female (allot)	Start age class	1	End age class	6	Exposure Duration	6 years
Soil	Sandy loam						

Exposure Pathways

Direct soil and dust ingestion	✓	Dermal contact with indoor dust	✗	Inhalation of indoor dust	✗
Consumption of homegrown produce	✓	Dermal contact with soil	✓	Inhalation of soil dust	✓
Soil attached to homegrown produce	✓			Inhalation of indoor vapour	✗
				Inhalation of outdoor vapour	✓

Top 2 applied? Yes

Where top 2 method is applied, two produce categories use 90th percentile rates, while the remainder use the mean. Produce categories vary on a chemical-by-chemical basis. Where top 2 method is not used, all produce categories for all chemicals assume 90th percentile rates.

Report generated	26/05/2021
Report title	Grenfell Investigation into Potential Land Contamination Impacts
Created by	DJD at AECOM

BASIC SETTINGS

Land Use	Public Open Space (res C4SL)						
Building	Small terraced house						
Receptor	Female (res C4SL)	Start age class	4	End age class	9	Exposure Duration	6 years
Soil	Sandy loam						

Exposure Pathways

Direct soil and dust ingestion	✓	Dermal contact with indoor dust	✓	Inhalation of indoor dust	✓
Consumption of homegrown produce	✗	Dermal contact with soil	✓	Inhalation of soil dust	✓
Soil attached to homegrown produce	✗			Inhalation of indoor vapour	✗
				Inhalation of outdoor vapour	✓

Top 2 applied? Yes

Where top 2 method is applied, two produce categories use 90th percentile rates, while the remainder use the mean. Produce categories vary on a chemical-by-chemical basis. Where top 2 method is not used, all produce categories for all chemicals assume 90th percentile rates.

Building Small terraced house
