

# EU RISK MANAGEMENT PLAN (RMP)

**Eylea<sup>®</sup>**

**BAY 86-5321  
(Aflibercept)**

**No. 31.2**

Date of Report:  
11 JAN 2022

Confidential

**Eylea<sup>®</sup>**  
(Aflibercept)  
EU Risk Management Plan  
**Part I – Product(s) Overview**

---

**EU Risk Management Plan for Eylea<sup>®</sup> (aflibercept)**

**RMP version to be assessed as part of this application:**

RMP Version number: 31.2

Data lock point for this RMP: 05 JAN 2022

Date of final sign off: 11 JAN 2022

Other RMP versions under evaluation: EU RMP v.32.1 for ROP indication.

Rationale for submitting an updated RMP:

The RMP version 30.3 is updated due to the following procedures:

- . Completion of AZURE study (study no. 16598) as part of the pharmacovigilance plan and plan for post authorization efficacy studies.
- Removal of the safety concern “Posology utilized in marketed use” as a missing information.

**Eylea<sup>®</sup>**  
**(Aflibercept)**  
**EU Risk Management Plan**  
**Part I – Product(s) Overview**

---

Summary of significant changes in this RMP:

- Part I: Updated to present summary of significant changes compared to previous approved RMP version 30.3
- Part II SI: not updated
- Part II SII: not updated
- Part II SIII: not updated
- Part II SIV: not updated
- Part II SV: not updated.
- Part II SVI: not updated
- Part II SVII: Updated . Posology utilized in marketed use was deleted from the Missing information.
- Part II SVIII: Updated. Posology utilized in marketed use was deleted from the Missing information
- Part III: Updated . Deletion of the Azure study (study no.16598) from Part III.2 and Part III.3
- Part IV: Updated. Deletion of the Azure study (study no.16598).
- Part V: Updated.
- Posology utilized in marketed use was deleted from the Missing information.
  
- Part VI: Updated. Deletion of AZURE study's (study no. 16598) from post authorization development plan. Posology utilized in marketed use was deleted from the Missing information.
- 
- Part VII:
  - Annex 2 Table 1 was deleted (ongoing and planned additional PV activities) and AZURE study ((study no. 16598) entered in Table 2 (completed additional PV activities).
  - Annex 3 Deletion of the Azure study (study no.16598).
  - Annex 5: Deletion of the Azure study (study no.16598).
  - Annex 8: Major changes to the RMP in current version.

## Table of Content

<b>ADMINISTRATIVE INFORMATION ON THE RMP</b> .....	<b>5</b>
<b>Table of Content</b> .....	<b>7</b>
<b>Index of Tables</b> .....	<b>10</b>
<b>PART I Product(s) Overview</b> .....	<b>18</b>
Overview of Versions.....	21
Current RMP Versions under Evaluation.....	21
<b>PART II Module SI: Epidemiology of the Indications and Target Population</b> .....	<b>22</b>
SI.1 Indications.....	22
SI.2 Epidemiology of the disease .....	22
SI.2.1 Wet age-related macular degeneration (wet AMD) .....	22
SI.2.2 Central retinal vein occlusion (CRVO) .....	25
SI.2.3 Branch retinal vein occlusion (BRVO) .....	27
SI.2.4 Myopic choroidal neovascularization (myopic CNV).....	32
SI.2.5 Diabetic macular edema (DME).....	35
SI.3 Concomitant medication(s) in the target population.....	39
SI.3.1 Wet age-related macular degeneration (wet AMD) .....	39
SI.3.2 Central retinal vein occlusion (CRVO) .....	39
SI.3.3 Branch retinal vein occlusion (BRVO) .....	39
SI.3.4 Myopic choroidal neovascularization (myopic CNV).....	40
SI.3.5 Diabetic macular edema (DME).....	41
SI.4 Important co-morbidities found in the target population.....	41
SI.4.1 Wet age-related macular degeneration (wet AMD) .....	41
SI.4.2 Central retinal vein occlusion (CRVO) .....	44
SI.4.3 Branch retinal vein occlusion (BRVO) .....	44
SI.4.4 Myopic choroidal neovascularization (myopic CNV).....	45
SI.4.5 Diabetic macular edema (DME).....	45
<b>PART II Module SII: Non-Clinical Part of the Safety Specification</b> .....	<b>47</b>
SII.1 Key Safety findings (from non-clinical studies) and relevance to human usage.....	47
<b>PART II Module SIII: Clinical Trial Exposure</b> .....	<b>50</b>
SIII.1 Brief overview of development .....	50
SIII.1.1 Development in the indication "wet age-related macular degeneration (wet AMD)" .....	50
SIII.1.2 Development in the indication "macular edema secondary to central retinal vein occlusion (CRVO)" .....	52
SIII.1.3 Development in the indication "macular edema secondary to branch retinal vein occlusion (BRVO)" .....	54
SIII.1.4 Development in the indication "choroidal neovascularization secondary to pathologic myopia" (myopic CNV).....	55
SIII.1.5 Development in the indication "diabetic macular edema" (DME).....	57
SIII.2 Clinical Trial Exposure.....	59
SIII.2.1 Introduction and overview of studies considered for the calculation of exposure .....	59
SIII.2.2 Tabulated overview of exposure across of all studies .....	65

**Eylea®**  
(Aflibercept)  
EU Risk Management Plan  
**Part I – Product(s) Overview**

SIII.2.3 Duration of exposure (patient months).....	67
SIII.2.4 Number of active injections.....	72
SIII.2.5 Duration of exposure (in patient months) by age, sex, and ethnicity .....	78
SIII.2.6 Exposure in special populations .....	92
<b>PART II Module SIV: Populations not studied in Clinical Trials.....</b>	<b>97</b>
SIV.1 Exclusion Criteria in Pivotal Clinical Studies within the Development Program .....	97
SIV.2 Limitations to Detect Adverse Reactions in Clinical Trial Development Programmes	108
SIV.3 Limitations in Respect to Populations Typically under-represented in Clinical Trial Development Programmes.....	109
SIV.3.1 Children .....	109
SIV.3.2 Elderly .....	109
SIV.3.3 Pregnant or breast-feeding women .....	110
SIV.3.4 Patients with a medical history of hepatic impairment.....	110
SIV.3.5 Patients with renal impairment .....	111
SIV.3.6 Patients with other relevant co-morbidity .....	113
SIV.3.7 Patients with a disease severity different from the inclusion criteria in the clinical trial population.....	113
SIV.3.8 Sub-populations carrying known and relevant polymorphisms .....	113
SIV.3.9 Patients of different racial and/or ethnic origin .....	113
SIV.3.10 Conclusion on the populations not-studied and other limitations of the clinical trial development programme.....	114
<b>PART II Module SV: Post-authorisation Experience.....</b>	<b>115</b>
SV.1 Post-authorisation Exposure .....	115
SV.1.1 Method used to Calculate Exposure .....	115
SV.1.2 Exposure .....	115
<b>PART II Module SVI: Additional EU Requirements for the Safety Specification.....</b>	<b>119</b>
SVI.1 Potential for Misuse for Illegal Purposes.....	119
<b>PART II Module SVII: Identified and Potential Risks .....</b>	<b>120</b>
SVII.1 Identification of Safety Concerns in the Initial RMP Submission .....	120
SVII.1.1 Risks not considered important for Inclusion in the List of Safety Concerns in the RMP .....	120
SVII.1.2 Risks considered important for Inclusion in the List of Safety Concerns in the RMP.....	122
SVII.2 New Safety Concerns and Reclassification with a Submission of an Updated RMP .....	130
SVII.3 Details of Important Identified Risks, Important Potential Risks, and Missing Information .....	130
SVII.3.1 Presentation of Important Identified Risks and Important Potential Risks.....	138
SVII.3.2 Presentation of the Missing Information.....	230
<b>PART II Module SVIII: Summary of the Safety Concerns .....</b>	<b>231</b>
<b>PART III Pharmacovigilance Plan .....</b>	<b>232</b>
III.1 Routine Pharmacovigilance Activities.....	232
III.1.1 Specific Adverse Reaction Follow-up Questionnaires for safety concerns .....	232
III.1.2 Other Forms of Routine Pharmacovigilance Activities for safety concerns .....	232

## Index of Tables

Table Part I.1 – Product(s) Overview.....	18
Table SI.1: Age- and Sex-Standardized Prevalence a of BRVO from 15 studies participating in a meta-analysis (adapted from Rogers et al. (42)) .....	29
Table SI.2: Prevalence of BRVO in a nationwide, population-based, cross-sectional study in South Korea .....	30
Table SI.3: Overview of racial distribution, BRVO prevalence, and population mean age in population-based research that studied BRVO .....	32
Table SII.1: Key safety findings from non-clinical studies and relevance to human usage ....	47
Table SIII.1: No. of subjects who were exposed to Eylea in the wet AMD, CRVO, BRVO, myopic CNV and DME studies (all enrolled subjects) .....	65
Table SIII.2: Clinical trial exposure by treatment duration - Indication: wet AMD (SAF).....	68
Table SIII.3: Clinical trial exposure by treatment duration - Indication: CRVO (SAF).....	69
Table SIII.4: Clinical trial exposure by treatment duration - Indication: BRVO (SAF).....	69
Table SIII.5: Clinical trial exposure by treatment duration - Indication: myopic CNV (SAF) .....	70
Table SIII.6: Clinical trial exposure by treatment duration - Indication: DME (SAF) .....	71
Table SIII.7: Clinical trial exposure by treatment duration in wet AMD, CRVO, BRVO, myopic CNV, and DME (SAF) .....	72
Table SIII.8: Summary statistics for number of injections among wet AMD subjects (excluding sham injections, SAF) .....	73
Table SIII.9: Summary statistics for number of injections among CRVO subjects (excluding sham injections, SAF) .....	74
Table SIII.10: Summary statistics for number of active injections in the BRVO study VIBRANT through Week 52 (excluding sham injections, SAF).....	75
Table SIII.11: Summary statistics for number of injections among myopic CNV patients (excluding sham injections, SAF) .....	76
Table SIII.12: Summary statistics for number of injections among DME subjects (excluding sham injections, SAF) .....	77
Table SIII.13: Summary statistics for number of injections among wet AMD, CRVO, BRVO, myopic CNV, and DME patients (excluding sham injections, SAF).....	78
Table SIII.14: Number of subjects by treatment group and sex, age, and race in AMD Phase I-IV studies (SAF).....	79
Table SIII.15: Clinical trial exposure (duration in patient months) by demographic subgroups sex, age categories, and ethnicity in wet AMD subjects (SAF) .....	80
Table SIII.16: Number of subjects treated with Eylea by sex, age, and race in the 2 CRVO Phase III studies (SAF).....	81
Table SIII.17: Clinical trial exposure (duration in patient months) by demographic subgroups sex, age categories, and ethnicity in CRVO subjects (SAF) .....	82
Table SIII.18: Age distribution among women enrolled in the CRVO studies (SAF) .....	83
Table SIII.19: Number of subjects treated with Eylea by sex, age, and race in the BRVO Phase III study (SAF) .....	84
Table SIII.20: Clinical trial exposure (duration in patient months) by demographic subgroups sex, age categories, and ethnicity in BRVO subjects (SAF) .....	84
Table SIII.21: Number of patients treated with Eylea by sex, age, and race in the myopic CNV Phase III study (SAF) .....	85

Table SIII.22: Clinical trial exposure (duration in patient months) by demographic subgroups sex, age categories, and ethnicity in myopic CNV patients (SAF) .....	86
Table SIII.23: Number of patients treated with Eylea by sex and age in the myopic CNV Phase III study (SAF) .....	87
Table SIII.24: Number of subjects by treatment group and sex, age, and race in DME Phase I-III studies (SAF) .....	87
Table SIII.25: Age distribution among women enrolled in the pivotal Phase III DME studies VIVID-DME and VISTA-DME (SAF) .....	89
Table SIII.26: Clinical trial exposure (duration in patient months) by demographic subgroups sex, age categories, and ethnic origin in DME subjects (SAF) .....	90
Table SIII.27: Number of subjects by treatment group and sex, age, and race in wet AMD Phase I-IV studies, CRVO Phase III studies, BRVO Phase III study, myopic CNV Phase III study, and DME Phase I-III studies (SAF) .....	91
Table SIII.28: Clinical trial exposure (duration in patient months) by demographic subgroups sex, age categories, and race in wet AMD, CRVO, BRVO, myopic CNV, and DME subjects (SAF) .....	92
Table SIII.29: Clinical trial exposure by special populations in the pivotal wet AMD Phase III studies VIEW 1 and VIEW 2 (SAF) .....	93
Table SIII.30: Clinical trial exposure by special populations in the pivotal CRVO Phase III studies (SAF) .....	94
Table SIII.31: Clinical trial exposure by special populations in the pivotal BRVO Phase III study (SAF) .....	94
Table SIII.32: Clinical trial exposure by special populations in the pivotal myopic CNV Phase III study (SAF) .....	95
Table SIII.33: Clinical trial exposure by special populations in the pivotal randomized, controlled DME Phase III studies (SAF) .....	96
Table SIV.1: Exclusion criteria in the pivotal studies across the development program which are proposed/not proposed to be considered as missing information .....	97
Table SIV.2: Limitations of ADR detection common to clinical trial development programmes .....	108
Table SIV.3: No. of patients by age in Phase I-III AMD studies, Phase III CRVO studies, Phase III BRVO study, Phase III myopic CNV study, and Phase I-III DME studies (SAF) .....	110
Table SIV.4: No. of patients by race in Phase I-III AMD studies, Phase III CRVO studies, Phase III BRVO study, Phase III myopic CNV study, and Phase I-III DME studies (SAF) .....	114
Table SV.1: Post-marketing exposure by country and indication - data lock point 30 SEP 2017 .....	116
Table SVII.1: Overview of important identified risks .....	122
Table SVII.2: Overview of important potential risks .....	126
Table SVII.3: Overview of missing information .....	129
Table SVII.4: Number of subjects with endophthalmitis in the study eye (grouped term and included preferred terms) in randomized Phase III wet AMD studies from baseline through Week 96 (Pool 1, SAF) .....	139
Table SVII.5: Number of subjects with endophthalmitis (likely infectious origin) in the study eye (grouped term and included preferred terms) in the Phase III VIEW 1 extension study in AMD (SAF; all subjects treated with VTE in the extension

## **PART II: Safety Specification**

### **PART II**

### **Module SI: Epidemiology of the Indications and Target Population**

#### **SI.1 Indications**

Eylea (brand name: Eylea<sup>®</sup>) is indicated for adults for the treatment of:

- Neovascular (wet) age-related macular degeneration (wet AMD),
- Visual impairment due to macular edema secondary to retinal vein occlusion (RVO; branch RVO [BRVO] or central RVO [CRVO]),
- Visual impairment due to diabetic macular edema (DME),
- Visual impairment due to myopic choroidal neovascularization (myopic CNV).

These indications are described in this module in the following order: AMD, CRVO, BRVO, myopic CNV, and DME.

#### **SI.2 Epidemiology of the disease**

##### **SI.2.1 Wet age-related macular degeneration (wet AMD)**

###### Characteristics of target indication

Age-related macular degeneration (AMD) is a medical condition which usually affects older adults and results in a loss of vision in the center of the visual field (the macula) because of damage to the retina. It is a leading cause of severe central visual loss in older people (1), (2). With increased life expectancy, the proportion of people over 65 years of age is expected to double by 2030 (1) and the prevalence and burden of AMD is, therefore, expected to increase.

The stages of AMD are categorized as early, in which visual symptoms are inconspicuous, and late, in which severe loss of vision is usual. Late AMD has "dry" and "wet" forms (3). It is the advanced stages of each of these which are responsible for severe vision loss. Dry AMD may eventually lead to a more severe form called "geographic atrophy" (GA), which is characterized by deposits known as drusen and by atrophy of the photoreceptors in the macula. The first sign of wet or neovascular (exudative) AMD (in the following referred to as wet AMD) is serous or hemorrhagic fluid that causes the neuroretina to detach from Bruch's membrane. The fluid originates from a subretinal neovascular membrane. The detachment disturbs the fine arrangement of the photoreceptors and causes image distortion and vision loss (3), (4).

###### Incidence of target indication

A population-based study in Wisconsin, United States (US), the Beaver Dam Eye Study (5), reported a 15-year cumulative incidence for advanced wet AMD of 2.0%. The risk increased with age: in persons aged 43 to 54 years the 15-year cumulative incidence was 0.4% and rose to 2.9% for individuals aged 75 to 86 years.

A 5% sample of US Medicare medical claims data from the Standard Analytical File (n=1,041,009) was used to develop a longitudinal study cohort by the Wilmer Ophthalmological Institute investigators. The 3-year (1995-1998) incidence of wet AMD

**EYLEA<sup>®</sup>**  
(Aflibercept)  
EU Risk Management Plan

**Part II – Module SI: Epidemiology of the Indication(s) and Target Population**

---

ranged between 0.37% (95% CI, 0.35-0.38) and 1.14% (95% CI, 1.12-1.16) depending on the ascertained criteria chosen (6).

A population-based study, the Los Angeles Latino Eye Study (7), reported a 4-year incidence of early AMD of 7.5% and advanced AMD of 0.2%. The overall 4-year progression of any AMD in either eye was 9.2% (95% confidence interval [CI]: 8.3, 10.1). Increasing age was associated with higher rates of progression (test of trend,  $p < 0.0001$ ), ranging from 6.2% in people aged 40 to 49 years at baseline to 21.7% in those over 80 years of age. Age-specific incidence and progression of AMD in Latinos were lower than in non-Hispanic whites.

In the Netherlands the estimated yearly AMD incidence was 0.1% (8).

In Germany approximately 300,000 new cases of AMD are diagnosed each year, generating a yearly incidence of 0.4% (9).

A Nigerian study to determine the incidence of age-related macular degeneration in Nigerian people 50 years of age and older showed that the incidence of AMD between 1997 and 2004 was 3.2% (256 out of 7,966 patients) (10).

#### Prevalence of target indication

The overall prevalence of wet AMD and/or geographic atrophy (advanced dry AMD) in the US population among people 40 years and older is estimated to be 1.47% (95% CI, 1.38% to 1.55%), with 1.75 million citizens having AMD.

In the Baltimore Eye Survey (11) among people 40 years of age and older, the prevalence of wet AMD was 0.61% in whites and 0.11% in blacks. When directly adjusting for age (minimum variance method), the rate among whites was 1.82%.

In a Medicare study (12) among people 65 years of age and older, the prevalence of wet AMD was 2.2% (2.3% in women [65% of wet AMD population] versus 1.7% in men and 2.3% in whites versus 1.2% in blacks;  $p < 0.01$  for both gender and race differences).

In Europe (the EUREYE study), the prevalence of any AMD or wet AMD in either eye was reported as 3.32% and 2.29%, respectively. The corresponding percentages for AMD and wet AMD were reported in men versus women as follows: ages 65-69 years, 0.90% vs. 1.03%, 0.38% vs. 0.92%, ages 70-74 years, 1.97% vs. 2.36%, 1.40% vs. 1.42%, ages 75-79 years, 4.07% vs. 3.15%, 2.63% vs. 2.17%, ages 80 and older, 6.94% vs. 15.00%, 5.56% vs. 10.50%, and in ages 65 and older, 2.49% vs. 4.00%, 1.69% vs. 2.78% (13).

In Germany, about 1 to 4.5 million people are affected by AMD in a population of about 80 million people (1.25%-5.6%) (9).

The prevalence of AMD increases dramatically with age, with more than 15% of the white women older than 80 years having wet AMD and/or geographic atrophy. More than 7 million individuals have drusen measuring 125  $\mu\text{m}$  or larger and are, therefore, at substantial risk of developing AMD. Owing to the rapidly aging population, the number of persons having AMD is likely to increase by 50% to 2.95 million in 2020.

AMD is more prevalent among white than among black persons (14). A systematic review and meta-analysis by Kawasaki et al showed that among Asians 40 to 79 years of age, the age-specific prevalence of late AMD was comparable with that reported from white populations, but early AMD signs were less common among Asians (15).

**EYLEA<sup>®</sup>**  
(Aflibercept)  
EU Risk Management Plan

## **Part II – Module SI: Epidemiology of the Indication(s) and Target Population**

---

### Mortality in target indication

A 2005 report from the Age-Related Eye Disease Study (AREDS) (16) showed that during a median follow-up of 6.5 years, 534 of 4,753 participants (11%) died. Participants with advanced AMD had increased mortality compared to participants with few, if any, drusen (relative risk [RR] 1.41; 95% CI 1.08 to 1.86). Advanced AMD was significantly associated with cardiovascular deaths (RR 1.92; 95% CI 1.18 to 3.12).

### Potential health risk

The neovascular form of AMD is responsible for severe vision loss associated with the disease in 90% of the cases (4), (17), (18). As demonstrated in several studies (19), (20) this condition has serious implications on quality of life and is associated with increased risk of falls and depression. Wet AMD patients also reported that the need for assistance with daily activities was more than 10 times greater compared to controls (26.5% versus 2.2%;  $p < 0.0001$ ) and the prevalence of falls was 3 times that of the control group (13.3% versus 4.3%;  $p = 0.031$ ). Similar results were reported in Canada (20), and in a multicenter European study (18). In a 12-month prospective study in Vancouver (21), Canada community-dwelling women aged  $\geq 70$  years with wet AMD ( $n = 114$ ) had a significantly greater number of falls and almost twice the risk of injurious falls compared to women of the same age from that community without the condition who had recent normal eye exam ( $n = 132$ ). A mean of 0.37 injurious falls per person-year were experienced among wet AMD participants, compared to 0.16 injurious falls per person-year among non-wet AMD participants ( $p = 0.006$ ). The age-adjusted incidence rate for injurious falls, for individuals with wet AMD was 1.77 (95% CI 1.07 to 3.02) times higher than in those without the condition.

In a Nigerian study to determine ocular morbidity associated with age-related macular degeneration in the Nigerian population ( $N = 256$ ), 34 patients (13.3%) were bilaterally blind and 130 (50.8%) had bilateral visual impairment. Of the blind patients 13 (38.3%) had wet AMD and 6 (17.7%) had geographic atrophy. The authors concluded that AMD was the cause of blindness in 7.4% of the patient population (10).

### Demographic profile of target population

The target population as studied by some investigators is subjects 40 years of age and older with rates of disease increasing with increasing age (5), (22), (23).

Ethnic variations have been described suggesting a higher prevalence among whites (24). AMD is also more prevalent in older women compared to older men (5), (25).

On average, people with AMD are more likely to be elderly white women with hypertension, diabetes, or history of MI compared to people without the condition (12). In the large non-interventional study (NIS) OCEAN, in which patients treated with ranibizumab in a real-world setting are being observed in Germany ( $N = 5,606$  overall), the cohort of subjects with wet AMD ( $n = 3,614$ ) had a mean age of  $77.9 \pm 8.2$  years, 61.2% were females, 22.3% had a medical history of arterial hypertension, 5.5% of MI, 4.0% of stroke or apoplexy, and 0.1% of TIA (26). A similar demographic structure was found in a retrospective, comparative, non-randomized cohort study based on patients' real-world data from electronic medical record databases in Australia and the UK. The mean age in the Australian ( $N = 570$ ) and UK cohort ( $N = 2,755$ ) was  $78.5 \pm 6.8$  and  $78.0 \pm 8.1$  years, respectively, and 57.8% and 63.7%, respectively, were women (27).

### **SI.2.2 Central retinal vein occlusion (CRVO)**

#### Characteristics of target indication

Abruptly decreased vision and a "blood and thunder" retina are classic signs of CRVO, a retinal vascular disease first described by Leibreich in 1855 and Michel in 1878. Dilated tortuous retinal veins, optic disc hyperemia and edema, 360-degree intraretinal hemorrhages, and often massive central edema lead to an abrupt decrease in visual acuity (28).

Central retinal vein occlusion (CRVO) is an important cause of moderate to severe visual loss in older persons (29) and a serious risk factor for macular edema in CRVO (30). The pathogenesis of macular edema in CRVO remains uncertain but is likely multifactorial (31). Thrombosis of the central retinal vein results in venous stasis, leading to disc swelling, diffuse nerve fiber layer and pre-retinal hemorrhage, macular edema and cotton wool spots. There are two types of CRVO: non-ischemic and ischemic. The former has a better prognosis than the latter, which is often complicated by iris neovascularization and neovascular glaucoma. Usually CRVO occurs in the elderly with a peak of incidence in the sixth to seventh decade and is frequently associated with systemic vascular conditions including atherosclerosis, diabetes, and hypertension (31), (32).

Results of a small study (n=30) by Turello et al. 2010 (33) showed that 84.2% of patients over 50 years and 90.9% of patients under 50 years with CRVO were found to have one or more hemostasis-related risk factors. Other small studies could not consistently confirm an important role of impaired hemostasis as a major systemic risk factor for RVO (34, 35). However, in patients without acquired risk factors, screening analyses for thrombophilia were recommended (36). To date, classic systemic risk factors that are commonly considered to be the cause of retinal vein occlusion (RVO, central and branch) are: smoking, diabetes mellitus and arterial hypertension.

A longitudinal study aimed to identify risk factors associated with CRVO among 1,302 managed care enrollees (from 2001 to 2009) ≥55 years of age. Cox regression analysis was used to determine the hazard of CRVO. After adjustment for known confounders, blacks had a 58% increased risk of CRVO compared with whites (HR, 1.58; 95% CI, 1.25–1.99), and women had a 25% decreased risk of CRVO compared with men (HR, 0.75; 95% CI, 0.66–0.85) (37).

In a population-based, cross-sectional study to evaluate the prevalence and associated factors of retinal vein occlusion in the Korean National Health and Nutritional Examination Survey (2008–2012), the following risk factors were found to be significantly associated with any RVO (i.e. CRVO or BRVO) in multivariate logistic regression analyses after adjusting for all potential factors: advanced age (OR=1.72, 95%-CI: [1.27; 2.34]), hypertension (OR=2.56, 95%-CI: [1.31; 5.08]), history of stroke (OR=2.08, 95%-CI: [1.01; 4.45]), and hypercholesterolemia (OR=1.84, 95%-CI: [1.01; 3.35]) (38).

#### Incidence of target indication

CRVO remains a common cause of unilateral visual loss (39). After diabetic retinopathy, retinal vein occlusions, both branch and central, are the second most common cause of visual loss from retinal vascular disorders (40).

**EYLEA<sup>®</sup>**  
(Aflibercept)  
EU Risk Management Plan

## **Part II – Module SI: Epidemiology of the Indication(s) and Target Population**

---

Based on the 2008 world population, and on the prevalence rates ranging from 0.1% to 0.5% of the middle aged to older groups (32), (41), it was estimated, that 2.5 million adults were affected by CRVO worldwide (42).

In the Wisconsin Beaver Dam Eye Study in the US (4,926 residents, 43 to 84 years of age at baseline from 1990 to 1995), the 5-year cumulative incidence of CRVO was 0.2% (32) and the 15-year cumulative incidences was 0.5% (43). The incidence increased with age affecting 1.3% of those aged 65 to 74 years or older at Baseline (43).

In Australia, the 10-year cumulative incidence reported by the Blue Mountain Eye Study (44), 3,654 Australian residents 49 years of age and older from 1992 to 2004) for CRVO was 0.4%, which is similar to the cumulative incidence reported in the Beaver Dam Eye Study.

Based on the before-mentioned 2 studies, Petrella et. al. estimated the incidence of CRVO to be 0.04%/year in adults aged  $\geq 45$  years in Caucasian populations (45).

The 9-year cumulative incidence (1998-2007) of CRVO in a Japanese population was 0.3% and it significantly increased with increasing age (46).

### Prevalence of target indication

In the combined populations of the Atherosclerosis Risk in Communities Study (n=12,642; mean age, 60 years) and the Cardiovascular Health Study (n = 2824; mean age, 79 years), the prevalence of retinal vein occlusion was 0.3% (n=39) (47).

Combined individual-level data from 15 major population-based studies around the world estimated the prevalence of CRVO. Overall, the authors collated data for 68,751 participants from 15 studies from the US, Europe, Asia, and Australia. Of these participants, 43.7% were male, 48.4% were white, 27.1% were Asian, 17.2% were Hispanic, and 7.2% were black. The age- and sex-standardized prevalence (per 1,000 persons) was 0.65 in the pooled analysis. The standardized prevalence rates for CRVO in individual studies varied from 0.04 per 1,000 in the Cardiovascular Health Study (CHS) to 1.59 per 1,000 in the Blue Mountains Eye Study (42).

A longitudinal study aimed at determining the incidence of CRVO among managed-care enrollees (from 2001 to 2009)  $\geq 55$  years of age. Of 494,165 enrollees, 1,302 (0.26%) were diagnosed with CRVO over  $5.4 \pm 1.8$  years (37).

In the Hisayama study (N=1,775) of Japanese people 40 years of age and older, the prevalence of CRVO was 2 per 1,000 people (48).

In a population-based, cross-sectional study to evaluate the prevalence and associated factors of retinal vein occlusion in the Korean National Health and Nutritional Examination Survey (2008–2012), the crude prevalence (expressed as weighted estimate in %) of CRVO among the 25,765 evaluable participants with ophthalmic examination was  $<0.1\%$  (38).

### Mortality in target indication

In some clinical studies, overall mortality and cardiovascular mortality in CRVO patients have been reported to be similar to patients from the general US population without the condition (49), (50). A pooled data analysis from two US population-based cohort studies, the Beaver Dam Eye and the Blue Mountains Eye Study, evaluated cardiovascular and cerebrovascular mortality in patients with and without RVO (central or branch) (51). After adjusting for age, gender, body mass index, hypertension, diabetes, smoking, glaucoma, and

**EYLEA<sup>®</sup>**  
(Aflibercept)  
EU Risk Management Plan

**Part II – Module SI: Epidemiology of the Indication(s) and Target Population**

---

study site, RVO was not associated with cardiovascular-related mortality (Hazard ratio (HR)) 1.2, 95% CI 0.8 to 1.8) or cerebrovascular-related mortality (HR 0.9, 95% CI 0.4 to 2.1) among participants of all ages. However, in persons under 70 years of age, baseline RVO was associated with higher cardiovascular mortality (HR 2.5; 95% CI 1.2–5.2).

Potential health risk

CRVO may lead to moderate to severe vision loss (32) and with it to reduced quality of life and risks of injuries. A study which utilized the 25-item National Eye Institute Visual Function Questionnaire (NEI-VFQ-25) found that patients with CRVO had a clinically relevant decrease in their vision-related quality of life as they scored significantly lower than patients without ocular disease (52). Responses correlated most strongly with visual acuity in the better-seeing eye, the number of systemic medical conditions and patients' opinions about their general health.

Demographic profile of target population

CRVO frequency is commonly similar in men and women and occurs for the most part in persons over the age of 65 years (32), (42).

In the large NIS OCEAN, in which patients treated with ranibizumab in a real-world setting are being observed in Germany (N=5,606 overall), the cohort of subjects with CRVO (n=121) had a mean age of 70.3 ± 11.5 years, and 52.9% of CRVO subjects were females (26).

The findings from the Hisayama study (48) suggest that the prevalence of RVO (central and branch) is higher in Japanese than in other Asians or Caucasians.

### **SI.2.3 Branch retinal vein occlusion (BRVO)**

Characteristics of target indication

Branch retinal vein occlusion (BRVO) is a venous occlusion that can occur in any of the branches of the central retinal vein and is considered to be the most common form of retinal vein occlusions (RVOs) (53). In BRVO, abnormal arteriovenous crossing with vein compression, degenerative changes of the vessel wall and abnormal hematological factors constitute the primary mechanism of vessel occlusion. The first case of BRVO was described by Leber in 1877 (54). BRVO is classified according to its anatomical location either as major, when one of the major branch veins draining one of the retinal quadrants is involved, or as macular, when a small venous vessel draining a specific sector of the macula is occluded (55). In the superotemporal quadrant the incidence of BRVO is higher as compared to the other quadrants. A tendency to a greater number of arteriovenous (AV) crossing at the site has been suggested to be causative (53). In 66% of eyes with BRVO, there is occlusion of the major branch in the superotemporal quadrant followed by 22–43% of eyes with occlusion of the major branch in the inferotemporal quadrant (56).

Generally, risk factors for BRVO are consistent with those identified for CRVO (see also section on CRVO above). Risk factors for BRVO are eyes with focal retinal arteriolar narrowing or glaucoma history, a history of smoking, migraine headaches, asthma and increase in systolic blood pressure (57), as well as, hyperlipidemia, diabetes mellitus, thrombophilia, hypercoagulation, systemic vasculitis, and inflammatory diseases (53). Hypertension and atherosclerotic cardiovascular disease have been postulated to cause retinal arteriosclerotic changes, especially at the arteriovenous crossings, resulting in RVO through

**EYLEA<sup>®</sup>**  
(Aflibercept)  
EU Risk Management Plan

**Part II – Module SI: Epidemiology of the Indication(s) and Target Population**

---

endothelial cell damage and thrombosis (58). Arteriosclerosis resulting in arteriolar insufficiency has been described as a possible underlying etiologic factor resulting in BRVO (57), (59).

Incidence of target indication

The Beaver Dam Eye study (Wisconsin USA) (57) was a population-based (age 43-86 years) study where BRVO and CRVO were detected (if present) at baseline in 1988-90 (n = 4,068) and at three 5-year follow-up examinations (ending in 2005), by grading 30° color fundus photographs.

The 5-year incidence of BRVO in the Beaver Dam eye study was 0.6% (6/1,000). The incidence by age group was:

Age 43-54: 0.2% (2/1,000)  
Age 55-64: 0.5% (5/1,000)  
Age 65-74: 1.3% (13/1,000)  
Age 75-86: 0.9% (9/1,000) (32).

The 15-year cumulative incidence of BRVO was 18 per 1,000 (1.8%, 95% CI, 1.4%-2.2%) and varied with age reaching the highest rates (2.9%) at ages 65-74. The frequencies were similar in men and women (age-adjusted frequencies, 1.5% vs 2.1%, respectively, p=0.55).

The 15 years incidence (accounting for competing risk of death) by age groups was:

Age 43-54: 1% (10/1,000)  
Age 55-64: 1.5% (15/1,000)  
Age 65-74: 2.9% (29/1,000)  
Age 75-86: 2.3% (23/1,000) (57).

In right eyes as compared with left eyes, the overall 15-year cumulative incidence was similar (1.0% vs 0.9%, respectively; p=0.70) (57).

The Blue Mountain Eye Study (Australia) was a population-based cohort study of a suburban Australian population of ages 49 years and older at baseline (1992-94). The surviving baseline participants were invited to attend follow-up examinations after 5 years (1997-1999) and after 10 years (2002-2004). The 10-year cumulative incidence of BRVO was 1.2% (60).

Prevalence of target indication

A recent meta-analysis (42) pooled data from 15 studies totaling 68,751 participants (age range 30-101 years) from several countries. The age- and sex-standardized prevalence of BRVO in 11 studies that assessed  $\geq 2$  fundus fields of both eyes (n=49,869) was 4.4 per 1,000 people with a range between 0.26 and 6.85 per 1,000 people. The age and sex standardized prevalence of BRVO by the 15 individual studies representing over 8 countries is displayed in following Table SI.1.

### Mortality in target indication

In a prospective study in Denmark (61) to assess BRVO as a prognostic marker of mortality, cases of BRVO were identified from a background population of 5.4 million and compared for risk of mortality with the non-BRVO segment of this population. Standardized mortality rates were calculated.

A total of 329 BRVO patients (173 women, 156 men) born between 1902 and 1956 were identified. They were 39 to 91 years old when diagnosed between 1973 and 1998. Follow-up was concluded on 08 JUL 2004, when 144 deaths were recorded among the BRVO patients (74 women, 70 men), compared with an expected number of 145.5 deaths in the background population. The standardized mortality rate was 0.99 (95%-CI: 0.84-1.16). Thus, the overall mortality rate of the BRVO population was almost identical to the background population. Stratified analyses revealed no significant effect of age, gender, or time of diagnosis (61).

The study investigators noted that an association between BRVO and cardiovascular/cerebrovascular risk factors has previously been documented in cross-sectional studies. The outcome in this longitudinal study may have been influenced by interventions instituted after the diagnosis of BRVO was made and by preferential survival before the diagnosis of BRVO of the more fit patients with the necessary precursor condition of having arteriovenous nicking, which is more prevalent in subjects with diabetes and hypertension (61).

A Danish case-control study (62) with prospective follow-up data from Danish national registries covering 80% of the Danish population (4.4 million) was performed to study BRVO comorbidities. A total of 1,168 patients with photographically verified branch retinal vein occlusion and 116,800 controls aged ≥40 years when the occlusion was diagnosed in the corresponding case were selected. The mortality hazard ratio adjusted for sex and year of diagnosis and with age as the underlying time scale, was similar in cases and controls (hazard ratio 0.94, 0.85 to 1.05; p=0.30).

---

Potential health risk

BRVO is a component of retinal vein occlusion, which is the second most common retinal vascular disorder after diabetic retinopathy and is considered to be an important cause of visual loss (63).

Most BRVO cases (particularly major BRVO) result in retinal ischemia, predominantly affecting macular retinal ganglion cells, which are most vulnerable to ischemic damage, and pigmentary degeneration and/or epiretinal membrane that may develop in the foveal region secondary to prolonged macular edema (64).

Complications of BRVO include macular edema, ischemic maculopathy, retinal neovascularization, macroaneurysmal formation, retinal telangiectasia, retinal detachment, and vitreous hemorrhage (53, 56, 65, 66). The most common complications are macular edema, followed by retinal neovascularization, vitreous hemorrhage, or retinal detachment (53).

The average reduction in visual acuity for ischemic BRVO is 20/50 and for non-ischemic BRVO it is 20/60. In the retina, acute BRVO presents with flame-shaped hemorrhages, dot and blot hemorrhages, cotton wool spots, hard exudates, edema, and dilated tortuous veins in the affected eye. In the chronic phase after absorption of intraretinal hemorrhage, morphological signs are more subtle and include capillary non-perfusion, dilatation of capillaries, microaneurysms, teleangiectatic vessels, and collateral vessel formation, in addition to the previously mentioned complications (53).

A Danish case control study found that after a BRVO diagnosis, patients had an increased risk of developing arterial hypertension (incidence rate ratio 1.37, 95% CI: 1.15 to 1.57), diabetes (1.51, 1.17 to 2.04), congestive heart failure (1.41, 1.12 to 1.68), and cerebrovascular disease (1.49, 1.27 to 1.76) compared to the non-BRVO reference group (62).

Demographic profile of target population

BRVO affects most frequently patients at the age of 50 years and older, and the sex distribution is similar or includes a slightly higher female population (42), (53), (57).

In population-based research that studied BRVO, the racial distribution, BRVO prevalence, and population mean age was as summarized in Table SI.3.

**EYLEA<sup>®</sup>**  
(Aflibercept)  
EU Risk Management Plan

**Part II – Module SI: Epidemiology of the Indication(s) and Target Population**

**Table SI.3: Overview of racial distribution, BRVO prevalence, and population mean age in population-based research that studied BRVO**

Country/ Study	Ethnicity of Population	Prevalence (per 1,000 persons)	Mean age (years)
<b>USA</b>			
The Atherosclerosis Risk in Communities (ARIC)	77% White 23% Black	0.45	59.9
Beaver Dam Eye Study (BDES)	100% White	2.82	62.1
Cardiovascular Health Study (CHS)	83% White, 17% Black	0.26	78.7
Proyecto VER Study	100% Hispanic	6.85	56.9
Los Angeles Latino Eye (LALES)	100% Hispanic	6.02	54.9
<b>Europe</b>			
European Eye (EUREYE) study	100% White	1.48	72.7
Rotterdam study	98% White 1% Asian	1.60	69.0
<b>Asia- Pacific</b>			
Australia -	99% White	5.63	66.2
Blue Mountain Eye Study (BMES)			
China - Beijing Eye Study	100% Asian,	4.67	56.2
China - Handan Eye Study:	100% Asian	6.16	52
Taiwan – Shihpai Eye Study	100% Asian	3.45	71.8
Singapore – Singapore Malay Eye Study (SiMES)	100% Asian	2.82	58.7
Japan - Funagata study	100% Asian	3.87	60.0
Hisayama Study	100% Asian	9.32	61.9

Overall, the prevalence findings of these studies suggested that BRVO occurs more frequently and possibly at younger age among Asians and Hispanics compared to Whites.

A retrospective study of 95 patients with retinal vein occlusion was carried out to determine the clinical presentation and pattern of distribution of the condition in the local Malaysian population. There was no significant difference in the sex distribution of the subjects. When comparing racial distribution between BRVO and CRVO patients, in the BRVO group, 40% were Indians, 29% Malays, and 31% Chinese. For CRVO in contrast, the Indians made up only 20% of the cases, the Malays 38% and the Chinese 43% (67).

In the large NIS OCEAN, in which patients treated with ranibizumab in a real-world setting are being observed in Germany (N=5,606 overall), the cohort of subjects with BRVO (n=204) had a mean age of 71.2 ± 10.0 years, and 58.3% of BRVO subjects were females (26).

### SI.2.4 Myopic choroidal neovascularization (myopic CNV)

#### Characteristics of target indication

Choroidal neovascularization (CNV) is the most common vision-threatening complication of high myopia. The exact pathogenesis of myopic CNV remains unclear (68). In myopic populations, elongation of the eyeball and mechanical stress in the eye may induce choroidal ischemia followed by atrophy of the retinal pigment epithelium (RPE) and overlying retina and subsequent growth factor release (69). These changes may lead to the formation of breaks in Bruch's membrane (lacquer cracks), RPE atrophy, and subsequent CNV formation (70). Lacquer cracks and chorioretinal atrophic areas are predictive of an unfavorable course in

**EYLEA<sup>®</sup>**  
(Aflibercept)  
EU Risk Management Plan

## **Part II – Module SI: Epidemiology of the Indication(s) and Target Population**

---

pathologic myopia and are associated with macular atrophy and CNV (71). Blood vessels from the underlying choriocapillaris may grow through the ruptured Bruch's membrane and under the retina. The appearance of lacquer cracks and the presence of high levels of vascular endothelial growth factor (VEGF) and low levels of pigment epithelium-derived factor (PEDF) (72), are probably involved in the development of myopic CNV (70).

Myopic CNV usually appears at an earlier age than that associated with age-related macular degeneration (AMD) and the diameter of the lesion is usually smaller; however, myopic CNV is subfoveal in up to 89% of cases (70).

Myopic CNV can be classified into two groups: Type 1 is formed by well delimited lesions with early hyperfluorescence and little leakage in late phases of the angiogram. Type 2 is formed by lesions with early hyperfluorescence and leakage causing a neuroepithelial detachment (70).

### Incidence of target indication

Although a number of epidemiology studies in general and high myopia (> minus 5, > minus 6 or > minus 8 diopters) are available, little is known regarding the prevalence or incidence of pathologic myopia.

Among Caucasians in Australia and the United States, approximately 20% of the population has (simple) myopia. In many Asian countries, however, the incidence exceeds 20%. In the Tajimi Study (Sawada et al. 2008, (73), myopia among Asians was found to be roughly 2.5 times greater than among Caucasians, and the incidence of high myopia, defined as > minus 6 diopters, is approximately 2.3 greater.

Ohno-Matsui reviewed the medical records of 218 consecutive Japanese patients (325 eyes) with myopic fundus changes in the macula. During an average follow-up of 130 months, of the 325 highly myopic eyes, 33 eyes (10.2%) developed myopic CNV. The incidence was higher (34.8%) among the fellow eyes of patients with pre-existing CNV than among eyes of patients without pre-existing CNV (6.1%). CNV developed in 3.7% of patients with diffuse chorioretinal atrophy, in 20.0% with patchy atrophy, and in 29.4% with lacquer cracks (74).

In a retrospective cohort study using data from an administrative claims database in Taiwan (JAN 2009 to DEC 2011), the cumulative annual incidence of myopic CNV rose from 11.9/100,000 (95%-CI: [11.4; 12.4]) in 2010 to 12.5/100,000 (95%-CI: [12.0; 13.0]) in 2011 (75)

### Prevalence of target indication

CNV is the most common vision threatening complication of high myopia (68). The prevalence of choroidal neovascularization in people with highly myopic eyes was estimated at 5% of eyes (69, 70).

In a cohort examined by Lai et al. in 2008 (76), 11 % of highly myopic asymptomatic eyes with ≤-6 D were found to have posterior pole lesions, and more than 50 % had peripheral retinal lesions. In France, a retrospective study of 363 patients under 50 years of age who were referred to a tertiary care ophthalmology department found that 62% of CNV was secondary to pathologic myopia (77).

A retrospective cohort study using data from an administrative claims database in Taiwan (JAN 2009 to DEC 2011) (75) reported the prevalence of myopic CNV to be 0.017%

**EYLEA<sup>®</sup>**  
(Aflibercept)  
EU Risk Management Plan

**Part II – Module SI: Epidemiology of the Indication(s) and Target Population**

---

(n=9,068 myopic CNV patients identified over a total of 15,011.98 person-years of follow-up).

Mortality in target indication

No information was identified.

Potential health risk

The long-term prognosis for natural progression of myopic CNV over time is extremely poor. It is believed that, after the onset of CNV, chorioretinal atrophy expands outward from around the periphery of the CNV in the process of gradual shrinkage of the CNV, and that this is the primary cause of the decline in visual acuity and progression of central scotoma (78). Yoshida et al. found that approximately 90% of their patients had a visual acuity of 20/200 or less after 5 years, and almost all (96.3%) had a visual acuity of 20/200 after 10 years (79).

Degenerative myopia is estimated to be the seventh most common cause of blindness in adults in the US, is present in about 0.5% of the general population in Europe, and is estimated to represent 2% of all types of myopia (80). Caution should be exercised in interpreting these figures, however, as they date from the last century, and more recent publications are not available.

Myopic CNV usually appears at an earlier age than that associated with age-related macular degeneration (AMD) and the diameter of the lesion is usually smaller (70, 81). Serous retinal detachment is a risk as well with associated hemorrhages (81).

It has been estimated that 36% to 82% of eyes with CNV show lacquer cracks (69, 82).

Demographic profile of target population

Myopic CNV affects both men and women and occurs in young adults as well as those over 50 years of age.

In various studies of myopic CNV the population age ranged between 12 and 93 years and was younger on average compared to AMD populations (83). In the Japanese study by Yoshida et al., the age of the patient population ranged from 7 to 82 years [mean 48.3 (SD 14.8)] (79). In a retrospective cohort study using data from an administrative claims database in Taiwan (JAN 2009 to DEC 2011; n=9,068 myopic CNV patients identified) the mean age was 52.6 ± 16.5 years, and 39.0% were male (75).

CNV occurs in approximately 5% of eyes with pathologic myopia. Ethnic origin seems to influence the likelihood of developing pathologic myopia, with prevalence being higher in Asian populations and lower in African and Pacific island groups (83), (84). There is strong evidence that pathologic myopia has a genetic factor, based on studies in twins and in families with pathologic myopia. Pathologic myopia appears to be a multi-factorial and polygenic disorder that is genetically heterogeneous. The simultaneous development of CNV in both eyes is uncommon (83).

### SI.2.5 Diabetic macular edema (DME)

#### Characteristics of target indication

Diabetic macular edema is the result of retinal microvascular changes that occur in patients with diabetes mellitus. Thickening of the basement membrane and reduction in the number of pericytes is believed to lead to increased permeability and incompetence of retinal vasculature. This compromise of the blood-retinal barrier leads to leakage of plasma constituents into the surrounding retina, resulting in retinal edema and vision loss. The hypoxic state achieved through this mechanism can also stimulate the production of vascular endothelial growth factor (VEGF) (85, 86). The role of VEGF appears to be central, since it increases microvascular permeability (87, 88).

The ETDRS group defined DME, based on stereoscopic fundus photography, as an increase in retinal thickness at or within 1 disk diameter of the foveal center. This increase in thickness may be focal or diffuse, and hard exudates or macular cysts may or may not be present as well (ETDRS Group 1985). The term "clinically significant macular edema" (CSME) was introduced to characterize the severity of disease, and for treatment guidelines. Clinically significant macular edema meets at least 1 of the following 3 criteria: retinal thickening at or within 500 µm from the center of the macula; hard exudates at or within 500 µm from the center of the macula associated with thickening of the adjacent retina; an area or areas of retinal thickening at least 1 disk area in size, at least part of which is within 1 disk diameter of the center of the macula (89).

#### Incidence of target indication

- USA:

The 25-year cumulative incidence of DME in people with type I diabetes in the Wisconsin Epidemiologic Study of Diabetic Retinopathy (WESDR) was 29% (90). The 10-year incidence of DME in the WESDR was 20.1% in type I diabetics; 25.4% in insulin-treated type II diabetics, and 13.9% in non-insulin treated type II diabetics (91).

The 4-year incidence of DME in the Los Angeles Latino Eye Study was 5.4% (38/699) (92).

- EU and USA:

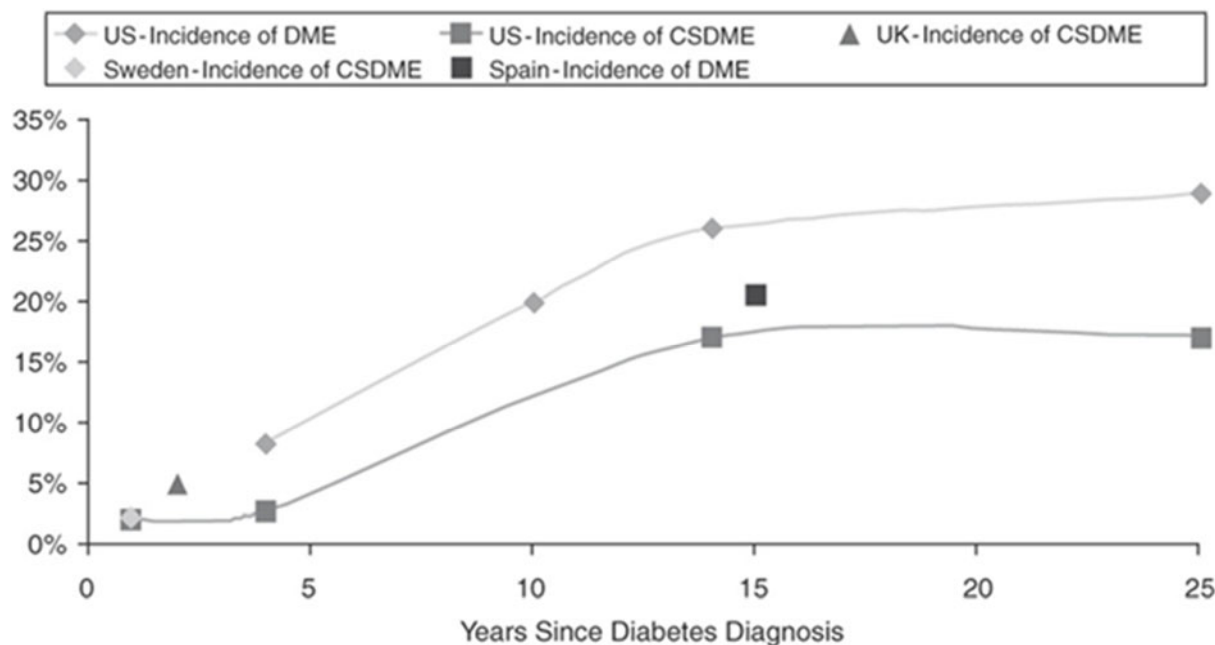

In a review of the literature, Chen et al. 2010 (93) provided a figure describing the increasing incidence of DME and CSDME over time in diabetic patients (see following figure). This information indicates a considerably higher DME risk in the US compared to EU countries, which continued to increase over time from the diagnosis of diabetes. The incidence rates of DME/CSDME in the overall diabetic population by reported countries were:

Sweden 1999 (94):	1-year CSDME:	2.3%
UK 2002 (95):	2-year CSDME:	4.79%
Spain 2007 (96):	15-year DME (type 1 diabetics):	20.5%

CSDME: clinically significant diabetic macular edema; DME: diabetic macular edema

Source: 12,14,24-26,29-31

There seems to be a decrease in the annual incidence of DME and CSDME over time in some countries. In WESDR, the annual incidence of DME was found to be lower in the last follow-up period compared with earlier follow-up periods (2.3% from 1980–2 to 1984–6, 2.1% from 1984–6 to 1990–2, 2.3% from 1990–2 to 1994–6, and 0.9% from 1994–6 to 2005-7) (90). The authors attributed the decline to better glycemic control (i.e., decreasing glycosylated hemoglobin), decreasing mean arterial blood pressure level, and earlier treatment of hypertension. A clinic-based study in Denmark also showed a decline in the incidence of DME in patients over time. The incidence after 15 years of diabetes duration was 11% and 12% for patients diagnosed in 1965–1969 and 1970–1974, respectively, while only 5% for patients diagnosed in 1975–1979 (90).

#### Prevalence of target indication

In 2010, of an estimated 285 million people worldwide with diabetes, over one-third had signs of diabetic retinopathy (DR), and a third of these are afflicted with vision-threatening retinopathy, defined as severe non-proliferative DR or diabetic macular edema (DME) (97).

The global prevalence of diabetes for all age groups is expected to increase from 2.8% in 2000 to 4.4% in 2030. The total number of people with diabetes is predicted to rise to 300 million by the year 2025, with the most significant increases in developing countries, due to population growth, aging, obesity and sedentary lifestyles (98).

The prevalence of DME is strongly related to the duration of diabetes. In the USA, an estimated 29% of adults with diabetes have DR and 3% have DME (99). In a cross-sectional

**EYLEA®**  
(Aflibercept)  
EU Risk Management Plan

**Part II – Module SI: Epidemiology of the Indication(s) and Target Population**

---

study of 778 individuals with ages 45 to 85 years with diabetes, participating in the Multi-Ethnic Study of Atherosclerosis (MESA) (100), the prevalence of any retinopathy was 33.2% and macular edema 9.0%. When looking at racial distribution, the prevalence of macular edema was significantly higher in Blacks (11.1%) and Hispanics (10.7%) than in Whites (2.7%) and Chinese (8.9%) (p=0.007). Data from the Wisconsin Epidemiologic Study of Diabetic Retinopathy (WESDR) (101) showed that after 15 years of known diabetes, the prevalence of DME was 18% in patients with type I diabetes, 20% in patients with type II diabetes who are taking insulin, and 12% in patients with type II diabetes who do not take insulin.

Outside of the USA, rates in diabetic populations have been reported as follows:

Spain: A population-based study of 8,187 type II diabetes and 488 type I diabetes patients in Spain in 2008 reported a yearly prevalence of 5.7% for macular edema in type I diabetes and 6.4% in type II diabetes (102).

India: The overall prevalence of macular edema in a population-based cross-sectional study (Sankara Nethralaya Diabetic Retinopathy Epidemiology and Molecular Genetics, (103) was 31.76% (95%-CI: 26.04 – 37.47). The prevalence of macular edema was higher in persons with known diabetes than in those with newly diagnosed diabetes (32.9% vs. 13.3%).

Australia: In a population-based study of 2,177 diabetic adults aged  $\geq 25$  years in 42 randomly selected areas of Australia, 15.3% had retinopathy, and diabetic macular edema was present in 1.2% of these patients with retinopathy (n=4) (104).

South Asia: In a community-based cross-sectional study (2009) involving 10 general practices; 1,035 patients with type 2 diabetes were studied: 421 of South Asian and 614 of white European ethnicity. The prevalence of DME was 12% (105, 106).

Rural China: In a cross-sectional study of 6,830 Han Chinese aged 30 years and older from 13 villages, 387 participants (6.9%) were diagnosed with diabetes mellitus. The overall prevalence of macular edema in the diabetic population was 5.2% and of CSDME 3.5% (107).

A pooled analysis of 35 studies (1980–2008) (97) provided data from 22,896 individuals with diabetes. The overall prevalence for DME was 6.81% (6.74–6.89). Studies from the USA, Australia, Europe, and Asia were included. In the pooled data, 52% were female, 44.4% were Caucasian, 30.9% were Asian, 13.9% were Hispanic, and 8.9% were African American. The mean age was 58.1 years (range 3–97), median diabetes duration was 7.9 years (interquartile range [IQR] 3–16). The prevalence of DME in the different studies ranged between 54% (49%, 59%) in the ARIC study (USA) and 15.19% (14.17%, 16.21%) in the EDC study (USA).

The World Health Organization estimates that 346 million people worldwide have diabetes, and this is expected to rise as the number of people with diabetes has doubled over the last 3 decades (108). Diabetic retinopathy (DR) is the most common microvascular complication of diabetes and is a major cause of visual impairment (109-112). In the US, it is estimated that about 28% of subjects 40 years and older with diabetes have DR, and 4.4% have vision-threatening DR (99). Outside the US, the estimates of diabetic patients who have DR range from 18% (India) to almost 50% in western European countries (103, 112, 113). The rate of vision-threatening DR outside the US ranges from 5.3% to 10% (113, 114).

**Part II – Module SI: Epidemiology of the Indication(s) and Target Population**

---

Mortality in target indication

A 20-years follow-up of the Wisconsin Epidemiologic Study of Diabetic Retinopathy, WESDR (115) showed that clinically significant DME decreased survival in people with older onset (diagnosed at age >30) diabetes mellitus (hazard ratio [HR] 1.27, 95%-CI 1.01 to 1.61) compared to people in the older age group with diabetes but without clinically significant macular edema. Clinically significant DME in WESDR was also associated with increased all-cause and ischemic heart disease mortality in older-onset diabetic patients (HR, 1.55; 95%-CI, 1.25-1.92; and HR, 1.56; 95%-CI, 1.15–2.13, respectively) compared to people in the older age group with diabetes but without clinically significant macular edema, when adjusting for age and gender. After controlling for other risk factors, the association remained significant for ischemic heart disease mortality (HR, 1.58; 95% CI, 1.07–2.35; p=0.02) among those taking insulin.

In the Early Treatment Diabetic Retinopathy Study (ETDRS) (116), type I and type II diabetic retinopathy patients had an increased risk for all-cause mortality compared to none/mild non-proliferative diabetic retinopathy patients, mostly due to cardiovascular disease (55-56%). A multivariable analysis controlling for demographic, cardiovascular, and insulin intake variables, still showed increased mortality in diabetics due to macrovascular disease, proteinuria, increased serum creatinine, ulceration, amputation, and reduced visual acuity.

Potential health risk

In the WESDR study, clinically significant DME was associated with higher risk of ischemic heart disease in people with older onset diabetes who were taking insulin (HR 1.58, 95%-CI 1.07 to 2.35). Stroke and ischemic heart disease were not significantly associated with this condition in those not taking insulin (115). Also, in the WESDR, univariate analysis showed that the incidence of DME was associated with male sex, more severe diabetic retinopathy, higher glycosylated hemoglobin, proteinuria, higher systolic and diastolic blood pressure, and more pack-years of cigarette smoking. Multivariate analyses showed that the incidence of DME was related to higher baseline glycosylated hemoglobin (HR per 1% 1.17; 95%-CI, 1.10–1.25; p=0.001) and higher systolic blood pressure (HR per 10 mmHg 1.15; 95%-CI, 1.04–1.26; p=0.004) and marginally to proteinuria (HR 1.43; 95%-CI, 0.99–2.08; p=0.06) (90).

A clinic-based study (Schepens Eye research Institute, Harvard, USA) (117) investigated the systemic and ocular factors associated with diffuse macular edema in patients with diabetic retinopathy (DR) in 160 DR patients. The risk of developing diffuse macular edema was 3.2 times greater in patients with high blood pressure (HBP) (95% confidence interval (CI), 1.5 to 6.9). Patients with cardiovascular disease (CVD) had a higher prevalence of diffuse (58.0%) than focal (26.0%) or no maculopathy (16.0%) (p=0.01). The odds for developing diffuse macular edema were 3.4 times greater in patients with vitreomacular adhesion (95%-CI, 1.15 to 13.30) than in those with complete posterior vitreoretinal attachment or vitreoretinal separation. The odds for development of diffuse macular edema were 7.7 times greater (95%-CI, 3.12 to 19.12) in patients with proliferative DR (PDR) in comparison with those with non-PDR (NPDR).

Demographic profile of target population

The target population is adults with type I or type II diabetes who have developed DME as a sequelae of diabetic retinopathy. Racial variations exist: In the third National Health and

**EYLEA<sup>®</sup>**  
(Aflibercept)  
EU Risk Management Plan

**Part II – Module SI: Epidemiology of the Indication(s) and Target Population**

---

Nutrition Examination Survey in the USA, the prevalence of diabetic retinopathy was 46% higher in blacks and 84 % higher in Mexican Americans than in Whites with diabetes (118).

In the large NIS OCEAN, in which patients treated with ranibizumab in a real-world setting are being observed in Germany (N=5,606 overall), the cohort of subjects with DME (n=1,211) had a mean age of 67.6 ± 10.9 years, and 41.9% of DME subjects were female. The majority of subjects (77.3%) suffered from T2DM; 9.6% had a medical history of T1DM (26).

In the WESDR, univariate analyses found that the incidence of DME was associated with male sex, more severe diabetic retinopathy, higher glycosylated hemoglobin, proteinuria, higher systolic and diastolic blood pressure, and more pack-years of cigarette smoking. Multivariate analyses showed that the incidence of DME was related to higher baseline glycosylated hemoglobin (HR per 1% 1.17; 95%-CI, 1.10–1.25; p=0.001) and higher systolic blood pressure (HR per 10 mmHg 1.15; 95%-CI, 1.04–1.26; p=0.004) and marginally to proteinuria (HR 1.43; 95% CI, 0.99–2.08; p=0.06) (90).

### **SI.3 Concomitant medication(s) in the target population**

#### **SI.3.1 Wet age-related macular degeneration (wet AMD)**

Eylea is approved in the EU and US for the treatment of wet AMD. Therapeutic options apart from Eylea to treat wet AMD include other IVT anti-VEGF therapies such as Macugen<sup>®</sup> (pegaptanib; approved) Lucentis<sup>®</sup> (ranibizumab; approved), conbercept (approved in the People's Republic of China), or bevacizumab (currently off-label), and photodynamic therapy in combination with verteporfin as photosensitizer. To date, intravitreal injections of anti-VEGF drugs have been the gold standard for the treatment of CNV secondary to AMD (119).

Eylea is administered as monotherapy; no systematic experience in terms of possible interactions with these alternative treatment approaches is currently available.

#### **SI.3.2 Central retinal vein occlusion (CRVO)**

Eylea is approved in the EU and US for the treatment of macular edema following RVO (including CRVO). Other therapeutic options besides Eylea to treat the macula edema caused by CRVO include other IVT anti-VEGF therapies such as Lucentis<sup>®</sup> (approved) or bevacizumab (currently off-label), IVT-applied corticosteroids such as dexamethasone (Ozurdex<sup>®</sup>) or triamcinolone acetate (Triesence<sup>®</sup>, Trivaris<sup>®</sup>), and panretinal photocoagulation (in the event of disease progression to anterior segment neovascularization).

Eylea is administered as monotherapy; no systematic experience in terms of possible interactions with these alternative treatment approaches is currently available.

#### **SI.3.3 Branch retinal vein occlusion (BRVO)**

Over the last three decades three main treatment options for macular edema secondary to BRVO have been developed:

- 1) Macular grid laser photocoagulation is considered to be the standard of care in BRVO since the mid 80's (63). Although grid laser photocoagulation showed benefits in a sizeable proportion of patients with perfused BRVO, in some patients poor vision persisted despite treatment (120). One principal concern with laser photocoagulation is, that the laser would cause sudden damage of the retina through coagulation, which would be an important

**EYLEA<sup>®</sup>**  
(Aflibercept)  
EU Risk Management Plan

**Part II – Module SI: Epidemiology of the Indication(s) and Target Population**

---

factor for permanent VA reduction. So especially in the presence of macular ischemia, effects of grid laser photocoagulation may be limited (120). The relatively low frequency of vision gain and delayed vision improvement following grid laser photocoagulation for BRVO, has prompted interest in other treatment modalities (for an overview see below and (121)).

- 2) Two different glucocorticoid drugs have been studied following IVT administration, (preservative-free) triamcinolone acetonide and, more recently, dexamethasone implants (Ozurdex<sup>®</sup>). For IVT triamcinolone acetonide results of the SCORE study (122) suggest that for macular oedema secondary to BRVO it is not more effective than the use of macular grid laser photocoagulation alone. A combination treatment showed a higher risk of adverse events and is therefore not recommended. The authors of the SCORE study group concluded that grid laser photocoagulation would still be the standard of care for macular oedema secondary to BRVO. The sustained-release IVT dexamethasone implant (Ozurdex<sup>®</sup>) received approvals for the treatment of macular oedema secondary to RVO from the US FDA in 2009 and in the EU in 2010. Two pivotal studies included a total subgroup of 291 BRVO eyes. In the 0.7 mg group of Ozurdex<sup>®</sup> the proportion of BRVO patients with VA gain  $\geq 15$  letters was 24% (0.7 mg dose group) at Day 90 compared to 15% in the sham control. This result was only statistically significant up to Day 90 of the study. At Day 180 the difference in the proportion of the 15-letter gainers was no longer statistically significant between groups. IVT dexamethasone is contraindicated in patients with glaucoma.
- 3) Numerous case series and uncontrolled studies have shown that IVT injections of anti-VEGF agents (bevacizumab and ranibizumab) can improve visual acuity (VA) and reduce retinal edema in patients with both BRVO and CRVO (30, 121, 123, 124). Only recently, a well-controlled study (BRAVO) of IVT ranibizumab has provided the first pivotal evidence that inhibition of VEGF is effective in the treatment of visual impairment due to macular edema secondary to BRVO (125, 126). Ranibizumab was approved for the treatment of macular edema following RVO by US FDA in 2010 and by European Commission in 2011.

Eylea has been approved in the EU and US for the treatment of macular edema following RVO.

### **SI.3.4 Myopic choroidal neovascularization (myopic CNV)**

Until recently, treatment modalities were limited to thermal laser photocoagulation for extrafoveal CNV and photodynamic therapy for juxtafoveal and subfoveal CNV (68), (83), (127), and possibly surgery (83). Both these modalities primarily aim at prevention of further visual loss with no improvement in vision (i.e., maintenance of vision) (70). Novel inhibitors of VEGF may now successfully restore visual acuity to some extent in patients with subfoveal myopic CNV (70), (83).

To date, both Eylea (by European Commission) and ranibizumab (by US FDA) are approved anti-VEGF agents for the treatment of myopic CNV. The recommended dose for Eylea is a single IVT injection of 2 mg. Additional doses should be administered only if visual and anatomic outcomes indicate that the disease persists. Recurrences are treated like a new manifestation of the disease.

**EYLEA<sup>®</sup>**  
(Aflibercept)  
EU Risk Management Plan

**Part II – Module SI: Epidemiology of the Indication(s) and Target Population**

---

### **SI.3.5 Diabetic macular edema (DME)**

Standard treatments for DME include focal/grid laser photocoagulation, IVT steroids, and vitrectomy for selected cases and advanced stages of DME. The disadvantage of laser photocoagulation and vitrectomy is the limited number of patients showing significant visual improvement. Many patients still lose VA despite these procedures, and in some cases, vision is further compromised as a result of these interventions. More recently, anti-VEGF compounds have been used in the treatment of DME. The effectiveness of anti-VEGF agents for the treatment of DME was demonstrated in several clinical studies. Based on the data from the pivotal Phase III studies RISE and RIDE (128), the Phase II study RESOLVE (129), and the pivotal Phase III study RESTORE (130), ranibizumab was approved in the EU and in the USA for the treatment of DME in 2011 and 2012, respectively.

Additionally, ranibizumab with prompt or deferred laser treatment demonstrated superior efficacy compared to laser alone in a large randomized clinical trial sponsored by The Diabetic Retinopathy Clinical Research Network. At Year 1, the mean change in BCVA letter score was statistically superior for the ranibizumab + prompt laser group (+9 letters) and the ranibizumab + deferred laser group (+9 letters) compared with the laser group (+3 letters). A significantly greater proportion of patients gained  $\geq 15$  letters for the ranibizumab + prompt laser group (29.0%) and the ranibizumab + deferred laser group (26.7%) compared with the laser group (14.2%). The mean central retinal thickness was significantly reduced from baseline for the ranibizumab + prompt laser group (-112  $\mu\text{m}$ ) and the ranibizumab + deferred laser group (-111  $\mu\text{m}$ ) compared with the laser group (-79  $\mu\text{m}$ ). There were also significantly greater proportions of eyes with  $\geq 2$ -step improvement in the Diabetic Retinopathy Severity Scale for the ranibizumab + prompt laser group (20.9%) and the ranibizumab + deferred laser group (21.4%) compared with the laser group (6.2%). There were 3 injection-related cases of infectious endophthalmitis in the ranibizumab-treated groups. Elevation of IOP was reported more frequently in eyes in the triamcinolone + prompt laser group (50%) than in the ranibizumab (9%) or sham (11%) groups (131).

The favorable results for ranibizumab plus prompt or deferred laser were sustained through the second and third years of the study, which constitutes the extent of the currently available evidence (132, 133).

Eylea has been approved in the EU and US for treatment of DME. The recommended dose for Eylea is 2 mg aflibercept administered by IVT monthly (once every 4 weeks) for the first 5 consecutive doses, followed by one injection every 2 months (8 weeks).

### **SI.4 Important co-morbidities found in the target population**

#### **SI.4.1 Wet age-related macular degeneration (wet AMD)**

Important co-morbidities in the AMD population include glaucoma, cataract, stroke, hypertension, and hyperlipidemia. In a case control study of 26,057 wet AMD patients and an equal number of controls from the Medicare population, wet AMD subjects had at least 20% higher odds for hypertension, hypercholesterolemia, emphysema, chronic obstructive pulmonary disease, atherosclerosis, arthritis, coronary heart disease, cataract, glaucoma, and myopia (134).

In a combined cross-sectional and cohort study of 1,519,086 Medicare enrollees identified between 2000 and 2003, the prevalences of hypertension, diabetes, and history of MI were

**EYLEA<sup>®</sup>**  
(Aflibercept)  
EU Risk Management Plan

**Part II – Module SI: Epidemiology of the Indication(s) and Target Population**

---

75%, 33%, and 5%, respectively, in the wet AMD group. In contrast, they were 73%, 27%, and 4.68% in the non-wet AMD group, and 65%, 25%, and 4.54% in the non-AMD group ( $p < 0.01$  for comparing the prevalence in wet and non-wet AMD versus non-wet AMD groups) (12).

A study to determine the incidence, pattern and ocular morbidity associated with age-related macular degeneration (AMD) at the Guinness Eye Center Onitsha Nigeria examined 256 AMD patients of all types. Systemic co-morbidities were hypertension and diabetes; the main ocular co-morbidities were cataract and glaucoma (10).

A 2011 German publication hypothesized the following: “Oxidative Stress at the retinal level is the common pathway in the development of AMD and cataract. AMD and cataract are not two independent processes. Cataract is a self-defense reaction of the retina to reduce oxidative stress and retinal damage” (135).

While in a German study of 45 wet AMD patients, who were injected with anti-VEGF treatment, no history of glaucoma was detected (136), another study of intraocular pressure (IOP) post anti-VEGF agents in wet AMD patients found the following: Of the 215 eyes receiving injections with bevacizumab and/or ranibizumab, 6% (n=13) had sustained IOP elevation requiring medical or laser interventions. Of the eyes receiving only bevacizumab, 9.9% (10/101) had sustained elevated IOP, while 3.1% (3/96) of eyes receiving only ranibizumab experienced increases ( $p=0.049$ ). Patients with pre-existing glaucoma experienced higher rates of elevated IOP when compared with patients without pre-existing glaucoma (33% vs. 3.1% respectively;  $p<0.001$ ). The glaucoma subgroup had a lower median number of injections (6; interquartile range 5-10) compared with the non-glaucoma group (9.5; interquartile range 6-13.7;  $p=0.031$ ) (137).

In a rural Italian community, 210 patients (79%) 65 year of age and older participated in a study of risk factors for AMD and age-related maculopathy. Older age ( $p = 0.014$ ), prior cataract surgery ( $p < 0.001$ ) and hypertension history ( $p = 0.005$ ) were associated with the two conditions (138).

Stroke is also considered an important co-morbidity in the AMD patient population. A 5-year population-based follow-up study in Taiwan reported that wet AMD is associated with a higher risk of stroke in patients 65 years of age and older compared to a same age control group. The adjusted hazard ratio for stroke during the follow-up period was 2.21 ( $p = 0.001$ ) (139).

An Australian study followed participants for cardiovascular disease mortality. Of 3,654 baseline participants (1992-4) aged 49+ years, 2,335 were re-examined after 5 years and 1,952 after 10 years. Retinal photographs were graded using the Wisconsin System. History and physical examination provided data on possible risk factors. Deaths and cause of death were confirmed by data linkage with the Australian National Death Index. Among persons aged <75 years at baseline, early AMD predicted a doubling of cardiovascular mortality (RR, 2.32; 95% confidence interval (CI), 1.03 to 5.19), over the next decade, after controlling for traditional cardiovascular risk factors. Late AMD predicted 5-fold higher cardiovascular mortality (RR, 5.57; 95% CI, 1.35 to 22.99) and 10-fold higher stroke mortality (RR, 10.21; 95% CI, 2.39 to 43.60) after adjusting for age and sex only. These associations were not present when persons older than 75 were included (140).

**EYLEA<sup>®</sup>**  
(Aflibercept)  
EU Risk Management Plan

**Part II – Module SI: Epidemiology of the Indication(s) and Target Population**

---

In a study to investigate whether AMD is associated with the development of ischemic and hemorrhagic stroke among elderly Americans, Medicare data were utilized. Baseline demographic variables and chronic conditions (AMD and type, history of MI, stroke, hypertension, and diabetes) were defined based on the occurrence of relevant ICD-9 codes in relevant diagnosis fields of the baseline Medicare Data. A total of 215,900 persons who had a diagnosis of MI or stroke during baseline period were excluded to form a cohort of 1,303,186 individuals who were free of major cardio-cerebral vascular disease (CVD) at baseline. The prevalence of AMD was 10.6%, with 19.7% being wet AMD and 80.3% being non-wet AMD. Baseline age, gender, race, hypertension, and diabetes adjusted 2-year incident odds ratios and 95% confidence interval of stroke associated with AMD were 1.31 (1.26, 1.36) for wet AMD, 1.18 (1.15, 1.21) for non-wet AMD, and 1.21 (1.18, 1.23) for either neovascular or non-wet AMD. The conclusion was that the findings are suggestive of an association between AMD, especially wet AMD, and incident stroke, independently of demographic factors and co-morbidity (141).

In the Women's Health Initiative Sight Examination (WHISE) study, on the other hand, stroke was not found to be a risk factor for AMD. A total of 4,288 women aged 63 years and older participated. Prevalence of any AMD was 21.4% (n = 919). Of those with AMD, 5.8% (n = 53) had signs of exudative AMD (n = 39) or pure geographic atrophy (n = 14), limiting the power to examine associations. Significant associations between late AMD and CVD risk factors were (odds ratio [OR], 95% CI) older age (1.19, 1.13 to 1.27, p<.0001), more pack years smoked (1.02 per pack-year smoked, 1.003 to 1.03, p=0.01), systolic blood pressure (0.84 per 10 mm Hg, 0.71 to 0.995, p=0.04), report of taking calcium channel blockers (2.49, 1.21 to 5.12, p=0.04), self-reported history of diabetes (2.00, 1.01 to 3.96, p=0.05), and greater body mass index (1.05 per 1 kg/m<sup>2</sup>, 1.001 to 1.10, p=0.05). History of MI, stroke, use of statins, or white blood cell count was not associated with AMD (142).

A report from a case series in Frankfurt, Germany, indicated that AMD patients who took anticoagulants and antiplatelet agents tended to develop large subretinal hemorrhages compared to non-AMD patients. Moreover, arterial hypertension was reported to be a strong risk factor for large subretinal hemorrhages in AMD patients receiving anticoagulants or antiplatelet agents (143).

The AMD patient population has shown higher odds of hyperlipidemia than the general population (134). The Beaver Dam Offspring Study (32) reported that older age, male sex, more pack-years of cigarettes smoked, higher serum high-density lipoprotein cholesterol level and hearing impairment were associated with early AMD.

The association between arteriosclerosis and AMD was studied in a cross-sectional study with 730 patients from the Munster age and retina study (MARS) which examines patients in the age range 60 to 80 years who were referred by ophthalmologists from the Muenster area. Patients with narrow angle glaucoma were excluded. All patients underwent a standardized ophthalmoscopic examination and were classified into four groups: without AMD (n=190), with unilateral or bilateral early forms of AMD (n=340), with unilateral late forms of AMD (n=139) and with bilateral late forms of AMD (n=50). The mean age was 72 years, 58% were women and the sex distribution within groups did not differ significantly. Risk factors for arteriosclerosis such as diabetes, body-mass-index and hypertension did not differ significantly. The number of smokers increased significantly with the severity of AMD (p=0.02). Associations with lipids were examined, adjusting for age and sex, and showed

**EYLEA<sup>®</sup>**  
(Aflibercept)  
EU Risk Management Plan

**Part II – Module SI: Epidemiology of the Indication(s) and Target Population**

---

significant decrease of HDL ( $p=0.087$ ) and significant increases of the HDL/LDL quotient ( $p=0.0007$ ). The non-fasting triglyceride values ( $p=0.0058$ ) correlated with the severity of AMD. The conclusions was that there was a highly significant, direct association of indicators of dyslipidemia such as increasing HDL/LDL quotient and decreasing HDL with increasing severity of AMD (144).

#### **SI.4.2 Central retinal vein occlusion (CRVO)**

A clinic-based case control study compared 408 patients with CRVO aged 21 years and older and 566 controls that were seen between 01 JAN 1990, and 31 DEC 2001 to determine risk factors for CRVO. An increased risk of CRVO was found in patients with systemic hypertension, but odds ratios were greater for older patients. Risk of CRVO also increases with hypercoagulability, diabetes mellitus, kidney disease, and glaucoma (145).

A population-based, cross-sectional study of 6,147 participants (whites, blacks, Hispanics, Chinese) from 6 US communities compared people with RVO (central and branch) to those without RVO. Independent risk factors associated with RVO were hypertension (OR 2.06, 95% CI 1.18 to 3.59), hypertriglyceridemia (OR 1.98, 95% CI 1.10 to 3.56), renal dysfunction (OR 1.85, 95% CI 1.01 to 3.39), presence of retinal arteriovenous nicking (OR 4.01, 95% CI 2.06 to 7.81) and focal arteriolar narrowing (OR 4.38, 95% CI 1.44 to 13.34) (146).

In a study comparing 117 patients (61 males, 56 females; mean age  $51 \pm 13$  years) with a history of RVO (62 CRVO, 48 BRVO, 7 both) to 202 age- and sex-matched control subjects, arterial hypertension was significantly more frequent in the RVO (central and branch) patients than in the control group (64.9% versus 28.2%, adjusted OR 4.5, 95% CI 2.4 to 7.9,  $p = 0.0001$ ). Diabetes was significantly more frequent as well (17.9% versus 7.9%,  $p = 0.05$ ) (147).

A longitudinal study aimed to identify risk factors associated with CRVO among 1,302 managed care enrollees (from 2001 to 2009)  $\geq 55$  years. Cox regression analysis was used to determine the hazard of CRVO.

After adjustment for known confounders, a diagnosis of stroke increased the hazard of CRVO by 44% (HR, 1.44; 95% CI, 1.23–1.68), and hypercoagulable state was associated with a 145% increased CRVO risk (HR, 2.45; 95% CI, 1.40–4.28). Individuals with end-organ damage from hypertension or diabetes mellitus had a 92% (HR, 1.92; 95% CI, 1.52–2.42) and 53% (HR, 1.53; 95% CI, 1.28–1.84) increased risk of CRVO, respectively, relative to those without these conditions (37).

A Medline literature review of RVO publications specified the following co-morbidities for CRVO: poor visual acuity at diagnosis, and presence of macular edema (which resolves in 30% of non-ischemic CRVO eyes and in up to 73% of ischemic CRVO eyes). Cardiovascular disease was indicated in association with RVO (148).

#### **SI.4.3 Branch retinal vein occlusion (BRVO)**

Cardiovascular diseases are important co-morbidities in people with BRVO. A meta-analysis of several BRVO studies showed that, in patients with BRVO, the odds for hypertension were 3.0 (95%-CI: 2.0–4.4), for hyperlipidemia 2.3 (95%-CI: 1.5–3.5), and for diabetes mellitus 1.1 (95%-CI: 0.8–1.5) compared to non-BRVO controls (149). Kaderli et al. (150) found that arterial stiffness as measured by pulse wave velocity and aortic distensibility was abnormal in BRVO patients, in comparison with both healthy and hypertensive controls.

**EYLEA®**  
(Aflibercept)  
EU Risk Management Plan

## **Part II – Module SI: Epidemiology of the Indication(s) and Target Population**

---

A retrospective case–control study of 60 patients younger than 50 years indicated that hypertension, hyperlipidemia, and body mass index were more prevalent in this patient group compared to controls (151). History of asthma and of migraine showed also increased odds for the development of BRVO (Odds ratio 2.00 and 2.73, respectively) (57). Glaucoma is among the ocular comorbid conditions in BRVO populations (53).

A Danish case-control study (62) with prospective follow-up data from Danish national registries covering 80% of the Danish population (4.4 million) was performed to study BRVO comorbidities. A total of 1,168 patients with photographically verified BRVO and 116,800 controls aged  $\geq 40$  years when the occlusion was diagnosed in the corresponding case were selected. Risk factors present 1 year before the diagnosis of BRVO included peripheral artery disease (odds ratio 1.83, 95%-CI: 1.14 - 2.95), diabetes (1.74, CI: 1.40 to 2.17), cardiovascular disease (2.07, CI: 1.79-2.40), and arterial hypertension (2.16, CI: 1.86 to 2.51). After the diagnosis, patients had an increased risk of developing arterial hypertension (incidence rate ratio 1.37, 95%-CI: 1.15 to 1.57), diabetes (1.51, 1.17 to 2.04), congestive heart failure (1.41, 1.12 to 1.68), and cerebrovascular disease (1.49, 1.27 to 1.76). The study conclusion was that diabetes, hypertension, and peripheral artery disease were associated with an increased risk of developing BRVO. BRVO was also associated with subsequently developing hypertension, diabetes, congestive heart failure, and cerebrovascular disease. These results fit the assumption that BRVO is a consequence of arterial thickening and that the arteriovenous crossing signs that precede it can be hallmarks of arterial disease (62).

### **SI.4.4 Myopic choroidal neovascularization (myopic CNV)**

Evidence suggest that eyes with myopic CNV tend to have an early stabilization of vision followed by gradual and progressive decrease in visual acuity (VA) over time primarily due to the development of chorioretinal atrophy around regressed CNV (68).

It has been estimated that 36 to 82% of the eyes with CNV show lacquer cracks while the latter's frequency among highly myopic eyes without CNV is considerably lower (0.6%) (70).

A retrospective study of (any) CNV patients younger than 50 years of age, who had been referred to a tertiary care ophthalmology department, was performed in Western Europe. CNV was associated with high myopia in 225 (62%) patients, pseudo-presumed ocular histoplasmosis syndrome in 42 (12%), angioid streaks in 17 (5%), and hereditary or traumatic or inflammatory disorders in 16 (4%) (77).

### **SI.4.5 Diabetic macular edema (DME)**

Diabetes is a leading cause of mortality and reduced life expectancy in the western world (152). In the USA it is ranked as the 6<sup>th</sup> leading cause of death accounting for over 71,000 deaths per year (116).

Diabetic retinopathy is the leading cause of vision loss in people 20 to 74 years of age in the developed world (118, 153)(118, 153) and macular involvement is the major cause of visual loss in patients with DR (117, 154).

A study investigated the systemic and ocular factors associated with diffuse macular edema in 160 patients with diabetic retinopathy (DR). The risk of developing diffuse macular edema was 3.2 times greater in patients with high blood pressure (95%-CI, 1.5 to 6.9). Patients with cardiovascular disease had a higher prevalence of diffuse (58.0%) than focal (26.0%) or no maculopathy (16.0%) ( $p=0.01$ ). The odds for developing diffuse macular edema were 3.4

**EYLEA<sup>®</sup>**  
(Aflibercept)  
EU Risk Management Plan

---

times greater in patients with vitreomacular adhesion (95%-CI, 1.15 to 13.30) than in those with complete posterior vitreoretinal attachment or vitreoretinal separation. The odds for development of diffuse macular edema were 7.7 times greater (95%-CI, 3.12 to 19.12) in patients with proliferative DR (PDR), respectively, in comparison with those with non-PDR (117).

(Aflibercept)  
EU Risk Management Plan

**Part II – Module SII: Non-Clinical Part of the Safety Specification**

---

## **PART II**

### **Module SII: Non-Clinical Part of the Safety Specification**

#### **Introduction**

A comprehensive toxicology program was conducted to support the clinical use as well as marketing authorization of aflibercept. The monkey was identified as the only relevant species for repeated-dose studies with intravitreal (IVT) administration. This module summarizes the relevant non-clinical findings. As an overall conclusion, none of the non-clinical findings are considered a safety concern for aflibercept requiring risk management activities other than information via the suggested label.

#### **SII.1 Key Safety findings (from non-clinical studies) and relevance to human usage**

**Table SII.1: Key safety findings from non-clinical studies and relevance to human usage**

<b>Key Safety findings (from non-clinical studies)</b>	<b>Relevance to human usage</b>
<ul style="list-style-type: none"> <li>• Potential to impair fertility.</li> <li>• Potential to be embryo-fetotoxic.</li> </ul>	<p><i>Results from animal studies with high systemic exposure indicate that aflibercept can impair male and female fertility. Such effects are not expected after ocular administration with very low systemic exposure. Although the systemic exposure after ocular administration is very low, aflibercept should not be used during pregnancy unless the potential benefit outweighs the potential risk to the fetus. Aflibercept is not recommended in women of childbearing potential not using contraception. Appropriate contraception during the treatment and for at least 3 months after the last administration has to be indicated for women who could possibly become pregnant.</i></p>

#### **Repeat-dose toxicity**

Repeated monthly IVT administration of aflibercept to monkeys for up to 8 months was not associated with ocular effects considered adverse, with ocular findings in the study limited to inflammation that were generally mild and completely or mostly reversed by 4-weeks post-dose.

Erosions and ulcerations of the respiratory epithelium of the nasal turbinates were observed in individual animals treated at and above the clinical dose of 2 mg/eye and with mostly low severity (exception: 1 animal with moderate, one with marked severity) at the end of the dosing period. However, assessing adverse events in clinical trials on humans including a substudy of one of the pivotal phase III studies (VIEW 2), serial nasal endoscopy and ears/nose/throat (ENT) specialist examinations of patients did not reveal any occurrence of these findings following repeated IVT dosing of aflibercept.

The target-organ toxicities observed after systemic administration of aflibercept occurred at exposures well in excess of the exposures achieved after IVT administration and are,

**EYLEA<sup>®</sup>**  
(Aflibercept)  
EU Risk Management Plan

**Part II – Module SII: Non-Clinical Part of the Safety Specification**

---

therefore, not considered relevant for the intravitreal use of aflibercept. The above clinical data resolved the possibly remaining concerns.

**Reproductive and developmental toxicity**

Effects on male and female fertility were assessed as part of the 6-month studies in monkeys with intravenous (IV) administration of aflibercept at doses ranging from 3 to 30 mg/kg. Absent or irregular menses associated with alterations in female reproductive hormone levels and changes in sperm morphology and motility were observed at all dose levels. Based on maximum concentration ( $C_{max}$ ) and area under the concentration time curve (AUC) for free aflibercept observed at the 3 mg/kg IV dose, the systemic exposures were approximately 4,900-fold and 1,500-fold higher, respectively, than the exposures observed in humans after IVT administration of 2 mg and are, therefore, considered not relevant for the intravitreal use of aflibercept. All changes were reversible.

No changes to reproductive organs were observed after IVT administration of aflibercept in monkeys.

Based on its mechanism of action, aflibercept is expected to influence embryo-fetal development. This was shown in an embryo-fetal development study in pregnant rabbits with IV administration (3 to 60 mg/kg). At 60 mg/kg fetal resorptions, pregnancy disruptions and numerous fetal (external, visceral and skeletal) malformations were observed. The maternal "No Observed Adverse Effect Level" (NOAEL) was the dose of 3 mg/kg, whereas the developmental NOAEL was not identified, since at 3 mg/kg still some signs of embryo-fetal toxicity were observed in one fetus. At the lowest dose of 3 mg/kg, systemic exposures of free aflibercept were approximately 600- to 2,000-fold in excess of the maximum human exposure after an IVT administration of 2 mg (based on AUC and  $C_{max}$ , respectively).

In a combined early embryonic / embryo-fetal development study with aflibercept in pregnant rabbits with subcutaneous (SC) administration (0.1 to 1 mg/kg) starting at gestation day (GD) 1, no influence on maternal toxicity, gestation rate, post-implantation loss, placental weight, placental appearance, fetal sex distribution, or fetal weight was observed at all doses tested. The overall rate of cardiac ventricular septal defects (with/without malformation of major vessels), and skeletal malformations was slightly higher in aflibercept treated than control animals but showed no clear dose-dependency. A "spina bifida" was seen in a single fetus from each of 2 different dams that received 0.1 mg/kg during gestation. A "meningocele" was seen in 1 fetus from a single dam that received 1.0 mg/kg during gestation. Based on the results of this study, the maternal NOAEL was considered to be 1 mg/kg. The developmental NOAEL was not identified. Comparison of the systemic exposures observed in this study with mean exposures observed in humans following a 2 mg/eye dose indicate an exposure margin of approximately 10-fold (based on mean AUC for free aflibercept).

These data support that treatment with aflibercept is not recommended during pregnancy unless the potential benefit outweighs the potential risk to the fetus. Likewise, aflibercept is not recommended in women of childbearing potential not using contraception.

**Organ toxicity (Nephro-/Hepatotoxicity)**

No signals indicating a potential for nephro- or hepatotoxicity were observed following intravitreal administration.

**EYLEA<sup>®</sup>**  
(Aflibercept)  
EU Risk Management Plan

**Part II – Module SII: Non-Clinical Part of the Safety Specification**

---

### **Genotoxicity**

In accordance with International Council for Harmonisation (ICH) guideline S6, no genotoxicity studies were conducted. Since aflibercept is a large molecule, it is not expected to interact directly with deoxyribonucleic acid (DNA) or other chromosomal material.

### **Carcinogenicity**

No studies explicitly targeting carcinogenicity were conducted. Based on studies performed so far, there is no evidence that aflibercept (or other VEGF-inhibitory compounds) act as growth factors or are immunosuppressive. Therefore, currently there is no reason to suspect that aflibercept has a tumorigenic potential.

### **General safety pharmacology / Drug interactions**

Effects of aflibercept on blood pressure and wound healing were only observed following systemic administration. Exposures after systemic administration were substantially above those following IVT injection. Therefore, IVT administration of aflibercept is not expected to exert appreciable effects on VEGF-mediated processes outside of the eye.

Since no overlapping substrate specificity in the metabolism of aflibercept and potentially co-administered small molecule drugs has to be expected, no drug interaction studies have been performed.

### **Conclusions on non-clinical data**

The following conclusions can be derived from the non-clinical data outlined above:

No important identified risks (confirmed by clinical data) were identified.

The non-clinical safety studies performed in monkeys and rabbits with systemic administration of aflibercept, suggest a potential of aflibercept to impair fertility and to exert embryo-fetotoxic effects. However, the systemic exposure to free aflibercept in these models was distinctly higher than the exposure observed in humans following intravitreal injection of 2 mg. Overall, aflibercept should not be administered during pregnancy, unless the potential benefit outweighs the potential risk to the fetus, and aflibercept is not recommended in women of childbearing potential not using effective contraception during treatment and for at least 3 months after the last dose. Clinical data on this issue are currently not available. The occurrence of embryo-fetotoxicity (regarded as important potential risk) is an objective of routine pharmacovigilance monitoring.

Erosions and ulcerations of the respiratory epithelium of the nasal turbinates, which were observed in individual monkeys in a repeat-dose IVT study, were not confirmed in a targeted sub-study within the clinical phase III study VIEW 2.

No signs of hepatotoxicity or nephrotoxicity were observed.

Studies focusing on genotoxicity, carcinogenicity, or drug interactions were not performed, since such endpoints are not applicable to the drug or are not relevant for IVT treatment.

Due to the low systemic exposure following the IVT route of administration, aflibercept is generally not expected to exert appreciable effects on VEGF-mediated processes outside of the eye.

Currently, there is no need for additional non-clinical investigations or research activities.

**Part II – Module SIII: Clinical Trial Exposure**

---

**PART II**  
**Module SIII: Clinical Trial Exposure**

**SIII.1 Brief overview of development**

Eylea (international nonproprietary name: aflibercept) was developed by Bayer AG and Regeneron Pharmaceuticals, Inc., as an effective treatment for a number of ophthalmologic conditions.

**SIII.1.1 Development in the indication “wet age-related macular degeneration (wet AMD)”**

The initial clinical development program for the indication neovascular (wet) age-related macular degeneration (AMD) consisted of 4 studies.

In 2005, the clinical development program was initiated by Regeneron Pharmaceuticals, Inc. with the start of the Phase-1 study VGFT-OD-0502 (SN 14395). This study provided the first evidence of a dose-response in the bioeffects of intravitreally (IVT) administered Eylea and indicated that single doses of less than 0.5 mg Eylea were associated with sub-optimal effects. At higher single doses, however, Eylea was associated with improvements in visual acuity and improvements in morphologic characteristics of the choroidal neovascularization (CNV) lesion. These improvements, which were evident for at least 1 month after a single injection, provided the first evidence of the durability of the effect of IVT Eylea in subjects with wet AMD.

In Phase-2 study VGFT-OD-0508 (SN 14394), which assessed 0.5 mg and 2 mg Eylea administered monthly or every 12 weeks and 4 mg Eylea administered every 12 weeks, all treatment groups experienced improvements in visual acuity as early as Week 1 and these improvements were maintained through Week 12 (the assessment of the primary efficacy endpoint). The improvement in visual acuity was maintained during Weeks 16 through 52 with an average of only 2 additional doses during this time. These results and the time course of improvements suggested that initiating treatment with 3 monthly injections was associated with a better outcome than a single injection of either 2 mg or 0.5 mg. In addition, the improvements in visual acuity were similar in all treatment groups at Week 8, suggesting that, in principle, the effects of Eylea may be maintained over an 8-week dosing interval without compromising efficacy. In the subsequent flexible-dosing phase of the study, when criteria-based dosing allowed for prolonged dosing intervals (i.e., subjects were only retreated if one or more of the protocol-specified retreatment criteria was met and there was no limit to how long a subject could go between treatments) the 0.5-mg dose did not perform as well as the 2-mg dose.

The dosing rationale for the Phase-3 studies was based on the improvements in best-corrected visual acuity (BCVA) seen in VGFT-OD-0508 (SN 14394) and the improvements in morphologic endpoints as assessed by optical coherence tomography (OCT) and fluorescein angiography (FA). The two pivotal studies (VIEW 1 [1y] and VIEW 2 [1y]) compared 0.5 mg and 2 mg Eylea dosed monthly and 2 mg Eylea dosed every two months (after an initial three-monthly injections) to ranibizumab 0.5 mg dose monthly. The rationale for including 2 mg Eylea dosed every two months was based on the observation from VGFT-OD-0508 (SN 14394) that, at Week 8, improvements in visual acuity after a single 2-mg dose were

**EYLEA<sup>®</sup>**  
(Aflibercept)  
EU Risk Management Plan

**Part II – Module III: Clinical Trial Exposure**

---

similar to those obtained with 2 mg dosed monthly, suggesting that a longer and less burdensome dosing interval (i.e., every 8 weeks) may be possible without sacrificing efficacy. In Year 2, the mandatory dosing interval was extended to 12 weeks, but subjects were allowed to receive injections more often, if certain re-treatment criteria were fulfilled (the treatment scheme in Year 2 is referred to as "modified quarterly dosing").

In the pivotal studies (VIEW 1 [1y] and VIEW 2 [1y]), the primary endpoint, proportion of subjects maintaining vision at Week 52, was met for all Eylea treatment regimens, was duplicated in both pivotal studies and the integrated analysis (1y) of the data from the pivotal studies, and established the non-inferiority of Eylea to ranibizumab (at a pre-specified 10% margin). The statistical test sequence employed in the two pivotal studies showed confirmatory results with very narrow confidence intervals.

In conclusion, administration of 2 mg Eylea administered every two months produced essentially the same efficacy results as monthly dosing of 2 mg Eylea or monthly dosing of 0.5 mg ranibizumab in subjects with wet AMD. In particular, this was clearly apparent in terms of the primary and clinically most important measure in the pivotal Phase-3 studies, visual acuity.

The efficacy and safety results from the pivotal Phase-3 studies showed that with 2 mg Eylea dosed every two months, subjects with wet AMD can undergo less frequent intravitreal injections, which are associated with certain risks, without sacrificing efficacy. While it cannot be excluded that a more frequent dosing with 2 mg Eylea could lead to even better results in some subjects, the vast majority of clinical subjects receiving 2 mg Eylea every two months, after three initial monthly doses, showed robustly good and durable improvements in vision as well as morphologic characteristics of the CNV lesion.

The results in Year 2 of the studies showed that the improvements achieved after 1 year of treatment were largely maintained on modified quarterly dosing with Eylea, particularly in those subjects continuing an exclusively proactive treatment. The latter were those just receiving the mandatory 3 injections over the course of Year 2.

Therefore, it can be concluded, that the benefits, in particular the possibility of prolonged, proactive dosing intervals of 8 weeks (or even longer, as suggested by the large proportion of subjects who were exclusively treated at intervals of 12 weeks in Year 2 of the pivotal studies) of a Eylea therapy, clearly outweigh potential risks arising from its use. Overall, the dosing experience in Year 1 and Year 2 of the pivotal studies suggested that Eylea treatment should be initiated with 1 injection per month for 3 consecutive months, followed by one injection every 2 months. After the first 12 months of treatment, the treatment interval may be extended based on visual and anatomic outcomes. In this case the schedule for monitoring should be determined by the treating physician and may be more frequent than the schedule of injections.

Based on these results and the favorable benefit/risk balance, the US Food and Drug Administration (FDA) was the first health authority to approve Eylea for the indication of wet AMD on 18 NOV 2011; EU approval was granted on 22 NOV 2012.

Patients originally enrolled in VIEW 1 who completed the core study period of 96 weeks had the opportunity to continue (or start) treatment with Eylea 2 mg in the open-label extension

**EYLEA<sup>®</sup>**  
(Aflibercept)  
EU Risk Management Plan

**Part II – Module SIII: Clinical Trial Exposure**

---

study VGFT-OD-0910 (SN 14832). A total of 320 out of 323 enrolled<sup>2</sup> patients from VIEW 1 received extension treatment in the study eye at individual injection intervals ranging from 4 to 12 weeks for an additional mean treatment duration of 25.8 months (range: 1 to 41 months). In conclusion, visual acuity as measured by BCVA was largely maintained with repeated long-term treatment, and treatment with Eylea was generally safe and well tolerated. No new safety signals were observed in this long-term extension study.

An additional AMD study was SIGHT (SN 13406), a randomized, double-masked, photodynamic therapy-controlled Phase III study of the efficacy, safety, and tolerability of IVT VEGF Trap-Eye in Chinese subjects with wet AMD. In addition to the exposure data, the safety results observed in the VIEW 1 extension study and in SIGHT were also considered in this RMP version.

Another additional study included in this RMP version is ALTAIR (SN 17668). This randomized, open-label Phase IV study assessed the efficacy and safety of intravitreal administration of aflibercept with two different approaches of Treat and Extend dosing regimen in Japanese subjects with wet AMD for up to 2 years; the 1-year data are considered for this RMP version.

### **SIII.1.2 Development in the indication "macular edema secondary to central retinal vein occlusion (CRVO)"**

The clinical development program for the indication “macular edema secondary to central retinal vein occlusion (CRVO)” comprised two pivotal Phase III studies, each comparing 2 mg Eylea IVT injections every 4 weeks (2Q4) for 20 weeks with sham injections every 4 weeks. Eligible subjects in both studies were randomized using a ratio of 3: 2 (Eylea: sham), with stratification by geographic region and baseline BCVA.

In the first 24-week period of both studies (i.e., Week 0 to Week 20), subjects received either 2 mg Eylea IVT injections every 4 weeks (2Q4), or sham injections every 4 weeks. The sham injection was performed by pressing a syringe barrel with no active drug to the conjunctival surface (without a needle or intraocular penetration).

In the next 28-week period (Week 24 through Week 52), subjects in both studies were evaluated monthly. In the COPERNICUS study, subjects in both treatment groups were eligible to receive either Eylea 2 mg IVT injections as clinically needed (PRN), according to protocol-defined retreatment criteria, or sham injections. In the GALILEO study, subjects in the Eylea group received either Eylea 2 mg IVT injections PRN, according to protocol-defined retreatment criteria, or sham injections. Subjects in the sham group continued to receive only sham injections.

Starting at Week 52, all subjects in the COPERNICUS study were eligible to continue in a 1-year PRN extension. Subjects were evaluated quarterly to receive 2 mg Eylea IVT injections according to the re-treatment criteria. Sham injections were not given during this

---

<sup>2</sup> Please note: Three subjects enrolled in the VIEW 1 extension study received Eylea 2 mg at Week 96 in the original VIEW 1 study (not counted for the VIEW 1 study exposure) but did not receive further treatment in the extension study. These 3 patients are considered for the safety analyses in the VIEW 1 extension study, and the 3 active injections at Week 96 are considered for the calculation of the AMD and overall exposure across studies.

**EYLEA<sup>®</sup>**  
(Aflibercept)  
EU Risk Management Plan

**Part II – Module III: Clinical Trial Exposure**

---

period. If, in the investigator's opinion, subjects required more frequent dosing, they may have been dosed as frequently as every 4 weeks.

Starting at Week 52, all subjects in the GALILEO study were eligible to continue in a 6-month PRN extension, with follow-up visits every 8 weeks through Week 76. In the Eylea treatment group, subjects received either 2 mg Eylea IVT injections or sham injections, according to the retreatment criteria. In the sham group, subjects received 2 mg Eylea at Week 52 unless the masked investigator decided - for medical reasons - that study drug treatment was not in the best interest of the subject. If Eylea was not administered at this visit, the subject received sham treatment. At Weeks 60 and 68, subjects in the sham group received either Eylea or sham treatment depending on the same retreatment criteria used from Week 24 in the Eylea treatment group. No treatments were administered at Week 76.

All subjects were eligible to receive panretinal photocoagulation (PRP) at any time during the study if they progressed to clinically significant ocular neovascularization.

The primary efficacy variable in both studies was the proportion of subjects who gained 15 letters or more of BCVA (using the ETDRS protocol) over baseline at Week 24. The primary efficacy variable was supported by secondary efficacy variables of change in BCVA from baseline to Week 24, change in CRT from baseline to Week 24, proportion of subjects progressing to any neovascularization by Week 24, and change in NEI VFQ-25 total scores from baseline to Week 24. Tertiary variables were assessed at the 52-week endpoint. Efficacy variables were assessed for each study individually (i.e., COPERNICUS and GALILEO) and in an integrated analysis of the pooled 6-month data from the two Phase-3 studies.

In both studies, Eylea administered 2Q4 was shown to be superior to sham treatment with regard to the proportion who gained  $\geq 15$  letters of vision during the first 24 weeks of treatment. In addition, all other efficacy results (i.e., secondary and tertiary) showed robust benefits. The results of the individual studies and the integrated analysis were consistent over all parameters investigated and confirmed the superiority of Eylea for improving visual acuity over observation alone in subjects with macular edema (ME) secondary to CRVO.

This clinical effect was largely sustained on continued active treatment with Eylea with less frequent PRN dosing up to Week 52 and a significant benefit of treatment was still shown at Week 76 (in GALILEO) or Week 100 (in COPERNICUS). However, the switch from proactive, fixed dosing at Week 24 to reactive PRN dosing gradually led to a mean loss up to approximately 1 line of BCVA. Moreover, the loss was accelerated when the monitoring interval was extended from 4 up to 12 weeks after the first year, suggesting that a proactive regimen might be more adequate to maintain achieved gains. Similar results were seen with most of the other efficacy measures.

Subgroup analyses showed that there are no restrictions regarding efficacy of Eylea in relation to organ function such as renal impairment, liver function, or diabetes status.

Overall, IVT injections of Eylea were safe and well tolerated. Differences seen in the incidence of some disease-related adverse events between the 2Q4 and PRN dosing phases may represent a de-stabilization of the disease with reactive PRN dosing that was well controlled with the proactive fixed-dosing regimen.

Based on these results and the favorable benefit/risk balance, the US Food and Drug Administration (FDA) was the first health authority to approve Eylea for the indication CRVO on

**EYLEA<sup>®</sup>**  
(Aflibercept)  
EU Risk Management Plan

---

21 SEP 2012. In Europe, Eylea was approved by the EMA in the CRVO indication on 26 AUG 2013. In Japan, treatment of CRVO with Eylea was approved by the MHLW in November 2013.

### **SIII.1.3 Development in the indication "macular edema secondary to branch retinal vein occlusion (BRVO)"**

The BRVO clinical development program was initiated by Regeneron Pharmaceuticals, Inc., building directly from the clinical development program of the approved indications AMD and CRVO (see aforementioned considerations). The design of the Phase III BRVO development program was based on advice given at several scientific advice meetings/letters with CHMP and FDA.

The clinical development program for BRVO consisted of one pivotal Phase III study (SN 15432, VGFTe RVO-1027, VIBRANT). VIBRANT was a randomized, double-masked, active controlled 52-week study of the efficacy, safety, and tolerability of repeated IVT administration of VEGF Trap-Eye compared with grid laser photocoagulation in subjects with macular edema secondary to BRVO. A total of 183 patients were randomized and exposed to study treatment (91 in the Eylea group and 92 in the laser group). The study was conducted by Regeneron Pharmaceuticals, Inc. in North America (USA, Canada) and Japan. The primary endpoint was the proportion of subjects who gained at least 15 letters in BCVA from baseline to Week 24. Study treatment (up to 48 weeks, followed by a 4 week observation period) was completed with LPLV on 10 MAR 2014.

Week 24 analyses showed that 53% of patients who received Eylea 2Q4 gained at least 15 letters in vision from Baseline at Week 24, compared to 27% of patients who received standard-of-care treatment with macular grid laser (primary endpoint;  $p < 0.001$ ). At Week 24, patients who received Eylea 2Q4 achieved a 17.0 letter mean improvement over Baseline in BCVA (a secondary endpoint) compared to a 6.9 letter mean improvement in patients who received laser ( $p < 0.0001$ ).

The final study data observed at Week 52 showed that the efficacy achieved at Week 24 (time of primary endpoint assessment) was maintained through Week 52, even with the treatment interval increased from monthly to every 8 weeks during the second study half: Subjects in the Eylea 2 mg group still demonstrated a nominally significant improvement in mean change in BCVA over subjects in the Laser+Eylea 2 mg group<sup>3</sup> from Baseline to Week 52 (mean change of 17.1 vs. 12.2 letters, LS mean change difference 5.2 letters, 95%-CI: [1.7; 8.7],  $p=0.0035$ ; FAS LOCF), treatment initiated with Eylea provided a higher proportion of subjects with an increase of  $\geq 15$  letters in BCVA at Week 52 compared to Laser+Eylea treatment (57.1% vs. 41.1%, adjusted difference 16.2%, 95%-CI: [2.0; 30.5],  $p=0.0296$ ; FAS LOCF), and Eylea led to a mean reduction in CRT, which was greater than Laser+Eylea 2 mg at Week 52 (mean change of -283.9 vs. -249.3 microns, LS mean change difference -29.5 microns, 95%-CI: [-54.7; -4.4],  $p=0.0218$ ; FAS LOCF). The subjects in the Laser+Eylea 2 mg group, who were not exposed to Eylea through Week 20, benefitted from the rescue treatment option with VEGF Trap-Eye (beginning at Week 24, if pre-specified eligibility criteria were

---

<sup>3</sup> Patients randomized to initial laser treatment had the opportunity to be treated with Eylea from Week 24 onwards (i.e., after the evaluation for the primary endpoint), if pre-specified eligibility criteria were met.

**EYLEA<sup>®</sup>**  
(Aflibercept)  
EU Risk Management Plan

**Part II – Module SIII: Clinical Trial Exposure**

---

met) by gaining approximately 5 letters in BCVA (1 line of vision) from Week 24 to Week 52.

Overall, the incidence of ocular TEAEs in the study eye through Week 52 was similar between the 2 groups (47.8% in the Laser+Eylea 2 mg group and 49.5% in the Eylea 2 mg group). Likewise, the incidence of non-ocular TEAEs was similar between groups (68.5% Laser+Eylea 2 mg and 67.0% Eylea 2 mg). The most common ocular TEAEs ( $\geq 5\%$ ) in the study eye were "conjunctival hemorrhage" (15.2% in the Laser+Eylea 2 mg group and 24.2% in the Eylea 2 mg group; this difference was due to the lower number of penetrating injections in the Laser+Eylea 2 mg group), "eye pain" (7.6% Laser+Eylea 2 mg and 5.5% Eylea 2 mg), and "eye irritation" (1.1% Laser+Eylea 2 mg and 7.7% Eylea 2 mg). Other individual ocular TEAEs in the study eye were low and mostly balanced between treatment groups. Treatment-emergent ocular AEs considered by the investigator to be related to the injection procedure in the study eye occurred with a higher frequency in the Eylea 2 mg group (29.7%) than in the Laser+Eylea 2 mg group (19.6%). Also, this difference was probably due to the lower number of penetrating injections in the Laser+Eylea 2 mg group. The incidence of SAEs through Week 52 was slightly higher in the Eylea group (10.9% on Laser+Eylea 2 mg and 15.4% on Eylea 2 mg). Only one study subject (in the Eylea 2 mg group) experienced an ocular SAE in the study eye ("traumatic cataract", which was considered injection-related). No drug-related SAEs were reported. Through Week 52, 2 study subjects experienced an adjudicated APTC event (both patients were in the Laser+Eylea 2 mg group; "cerebrovascular accident" occurred prior to any Eylea rescue and "myocardial infarction" occurred after first Eylea exposure) and there was one death (this patient, randomized to the Laser+Eylea 2 mg group, died from pneumonia prior to any Eylea rescue). Overall, the observed safety profile through Week 52 was as expected and in line with the Week 24 safety results. Eylea was generally well-tolerated with a favorable ocular and systemic safety profile after 52 weeks of treatment in this population of subjects with BRVO.

Based on the favorable Week 24 results that were used for the submission of a supplemental Biologics License Application, Eylea was approved for the treatment of BRVO patients by the FDA on 06 OCT 2014, and in the EU on 25 FEB 2015.

#### **SIII.1.4 Development in the indication "choroidal neovascularization secondary to pathologic myopia" (myopic CNV)**

The clinical development program for the indication "choroidal neovascularization secondary to pathologic myopia" consisted of one pivotal Phase III study comparing a single 2 mg Eylea IVT injection followed by additional injections up to every 4 weeks in case of recurring or persisting CNV with sham. Eligible patients were randomized in a ratio of 3:1 (Eylea: sham).

In the first 24-week period of the study, patients received either one mandatory 2 mg Eylea IVT injection at Baseline followed by sham injections every 4 weeks, which could be replaced by additional active injections in case of recurring or persisting CNV, or sham injections every 4 weeks only. Sham injections were performed by pressing a syringe barrel with no active drug to the conjunctival surface (without a needle or intraocular penetration).

In the next study period (Week 24 through Week 44), patients in both treatment arms (i.e., including the patients who were previously treated with sham) were allowed to receive active Eylea 2 mg treatment in the case of recurring or persisting CNV; otherwise, sham injections

**EYLEA<sup>®</sup>**  
(Aflibercept)  
EU Risk Management Plan

**Part II – Module III: Clinical Trial Exposure**

---

were administered for masking purposes. Initially, all patients in the sham group received one mandatory active injection at Week 24. Patients were evaluated monthly until Week 48.

The primary efficacy variable was the change in BCVA as assessed following the ETDRS protocol from Baseline to Week 24. The primary efficacy variable was supported by one confirmatory secondary efficacy variable of proportion of patients who gain  $\geq 15$  letters in both treatment groups.

Exploratory secondary variables included the proportion of patients who gain or lose certain amounts of letters of BCVA, the change in central retinal thickness assessed on OCT, the change in total CNV lesion size, and leakage as assessed by FA, as well as vision-related QoL as assessed by NEI-VFQ-25 and general health as assessed by ED-5D.

The primary and secondary efficacy analyses performed at Week 24 demonstrated superiority of Eylea over sham (i.e., no active intervention) in the treatment of myopic CNV. Clinically meaningful improvements compared to sham (with nominal p-values  $< 0.05$ ) were observed in all functional (BCVA) and morphological (CRT, CNV lesion size, leakage area) variables as well as in the NEI VFQ-25 total score. In contrast, the baseline disease conditions in the untreated sham group on average continued to persist, or even had deteriorated by Week 24. Beyond Week 24, the mean change in BCVA was maintained and even slightly increased until Week 48 in the Eylea 2 mg group; exploratory analyses of additional morphological and functional outcomes showed consistent improvements up to Week 48. In the Sham+Eylea 2 mg group, the mandatory start of active treatment with Eylea 2 mg as from Week 24 also resulted in clinically meaningful improvement in all efficacy variables up to Week 48. However, the magnitude of change did not reach the same level as in those patients treated with Eylea from the beginning of the study.

Overall, IVT injections of Eylea were safe and well tolerated through Week 48 in either treatment group. No patient died during the course of the study; the overall rate of treatment-emergent SAEs from Baseline through Week 48 was low with 8 study patients involved (6.6%; N=122). In the Sham+Eylea 2 mg group, the only SAE (PT: "VA reduced" in one patient [3.2%; N=31]) occurred in the study eye and was considered unrelated to treatment or injection. In the Eylea 2 mg group, 7 patients (7.7%; N=91) experienced a treatment-emergent SAE, including 3 patients (3.3%) with ocular and 4 patients (4.4%) with non-ocular treatment-emergent SAEs. Only one ocular treatment-emergent SAE (1.1%) occurred in the study eye, a macular hole that was regarded as related to study drug (and injection procedure and study procedure as well). All non-ocular treatment-emergent SAEs were classified as not related to study drug, study procedure, or injection. Only one non-ocular treatment-emergent SAE, a cerebral hemorrhage in the Eylea 2 mg group (1.1%), was classified as an APTC event by the masked Adjudication Committee. Some small differences between treatment groups in the incidence of non-ocular TEAEs were deemed attributable to the 3:1 randomization leading to uneven group sizes.

Based on the favorable benefit/risk balance observed at Week 24, the data obtained from the 15170 study (MYRROR) were submitted in Japan for market approval by PMDA in DEC 2013, and in SEP 2014 the approval for treatment of myopic CNV was received from Japanese Ministry of Health, Labour and Welfare (MHLW). In the EU, Eylea was approved for the treatment of myopic CNV on 28 OCT 2015.

EU Risk Management Plan

**Part II – Module III: Clinical Trial Exposure**

---

### **III.1.5 Development in the indication "diabetic macular edema" (DME)**

The clinical development program for the indication "diabetic macular edema (DME)" is comprised of 4 studies.

In 2006, the clinical development program was initiated by Regeneron Pharmaceuticals, Inc. with the start of the Phase I study VGFT-OD-0512. In this safety and tolerability study of IVT administered VEGF Trap-Eye in 5 patients with DME, a single 4 mg IVT dose of VEGF Trap-Eye was well tolerated. No dose-limiting toxicity was observed. Ocular adverse events (AEs) were mild, and none of the AEs were considered to be related to the study medication. No patient had detectable anti-VEGF Trap-Eye antibodies. Excess retinal thickness (ERT) and total macular volume decreased, and VA improved relative to baseline values.

In the Phase II, double-masked, randomized, controlled study DA VINCI (VGFT-OD-0706) of the safety, tolerability and biological effect of repeated IVT administration of VEGF Trap-Eye in patients with clinically significant DME, 2 doses of IVT administered VEGF Trap-Eye (0.5 and 2 mg) at 3 different dosing schedules (every 4 and 8 weeks, PRN) were compared to macular laser photocoagulation. A total of 221 subjects were randomized and 219 treated. Treatment with VEGF Trap-Eye was superior to laser therapy for the treatment of DME over 24 weeks and 52 weeks. At Week 24, treatment with VEGF Trap-Eye resulted in statistically significantly better mean best corrected visual acuity (BCVA) outcomes (gain of +8.5 to +11.4 letters), and greater mean reductions in retinal thickness (-127.3  $\mu$ m to -194.5  $\mu$ m) compared to the laser arm (gain of 2.5 letters and reduction of -67.9  $\mu$ m, respectively). At Week 52, treatment with VEGF Trap-Eye continued to show greater mean BCVA outcomes (gain of +9.7 to +13.1 letters) and greater mean reductions in retinal thickness (-165.4  $\mu$ m to -227.4  $\mu$ m) compared to the laser arm (-1.3 letters and -58.4  $\mu$ m, respectively).

Considering data from the AMD program and from the DA VINCI study, the dose advanced into the Phase III DME program (VIVID-DME and VISTA-DME) was 2 mg, and the dose regimens were every 4 weeks, and every 8 weeks (after 5 initial monthly doses). Although the DA VINCI study was not designed to distinguish among treatment groups, it was noted that a greater proportion of patients lost vision from baseline at Week 52 in the 0.5 mg group as opposed to the 2Q4 group. This further supported the decision to move forward with the 2 mg dose in DME, evaluating 2Q4 and 2Q8 regimens. The additional dose group studied in the DA VINCI study was 2 mg PRN, in which patients received as needed dosing after 3 initial monthly doses, but were required to be monitored on a monthly basis through Week 52. The 2Q8 and 2PRN groups ended up receiving a similar number of injections and had similar visual acuity and anatomic outcomes. In practice, the 2Q8 regimen would result in a lower burden of monitoring, and therefore the 2Q8 regimen was considered more practical than the 2PRN regimen. In addition, the every 8-week dosing paradigm has an advantage over the PRN dosing regimen in that treatment is delivered on a proactive basis and not in response to recurrence of disease. Therefore, it was decided not to move forward with the PRN dosing regimen in the Phase III DME program. Fluctuations in the 2Q8 group in CRT after the Q8 interval began led to the inclusion of an additional monthly dose in the Phase III DME program. This was done in an attempt to enhance the maintenance of CRT reduction once the maximum decrease in CRT was attained and augment the improvement in BCVA over the Q8 treatment interval. The addition of an extra dose (at Week 12) deferred the start of the first Q8 interval from week 8 to week 16, resulting in 5 initial monthly doses.

**EYLEA<sup>®</sup>**  
(Aflibercept)  
EU Risk Management Plan

**Part II – Module III: Clinical Trial Exposure**

---

A total of 872 patients were randomized and 865 patients (=SAF) treated in the pivotal Phase III DME studies VIVID-DME (404 subjects) and VISTA-DME (461 subjects). Consistently in both studies, Eylea administered 2Q4 and 2Q8 was shown to be superior to laser treatment with regard to the pre-specified primary efficacy analysis, i.e., the change from baseline in mean ETDRS letter score at Week 52, analyzed for the FAS using the LOCF approach. All supportive sensitivity analyses conducted to assess the robustness of these results confirmed the findings of the primary analysis. Also, in the analyses of the secondary efficacy variables the results for all visual acuity and anatomic efficacy variables supported the conclusion drawn from the primary variable that treatment with 2 mg Eylea once every 4 weeks or once every 8 weeks following 5 initial monthly doses is superior to laser treatment.

Results through Week 100 (2-year analysis) and through Week 148 (3-year analysis) of the studies supported the primary, secondary, and additional endpoints analyzed at Week 52 and showed that the effects of treatment with Eylea were maintained in all VA and anatomic endpoints.

The pooled safety analysis of the pivotal Phase III studies through Week 148 showed that Eylea was generally well tolerated.

The overall TEAE rate was without any notable difference compared to the laser treatment. However, since in the laser group, 85% of patients received additional or PRN treatment with VTE, the comparison of AE occurrence between laser and the VTE combined group is of limited value and conclusions should be drawn with caution in the outer years of the studies.

There were no differences compared to laser photocoagulation in the incidence of ocular or non-ocular TEAEs which raise safety concerns, e.g., the differences in drug-related non-ocular/ocular TEAEs, injection procedure-related ocular TEAEs, and non-ocular serious TEAEs.

In general, TEAEs consistent with the injection procedure were more common in the Eylea groups, whereas TEAEs consistent with disease worsening were more common in the laser group.

The most common ocular TEAEs in the study eye were "conjunctival haemorrhage", "cataract", and "eye pain". Most ocular TEAEs had a mild or moderate intensity; few were severe in intensity or were serious. The most common non-ocular TEAEs were "hypertension", "nasopharyngitis", "urinary tract infection", and "anaemia". In general, the frequencies of these events were similar between the Eylea groups and the laser group. Most non-ocular TEAEs had a maximum intensity of mild or moderate. The overall frequency of treatment-emergent APTC events was low and within the expected range in the DME population (22 patients [7.7%] in the laser group, 31 patients [10.7%] in the 2Q4 group, and 21 patients [7.3%] in the 2Q8 group). Any deaths through Week 148 were reported in 8 subjects (2.8%) in the laser group, 19 subjects (6.5%) in the 2Q4 group, and 13 subjects (4.5%) in the 2Q8 group. The causes of the deaths were consistent with the demographics and predisposition of the population being studied. No new ADRs were reported in the DME studies compared with those reported in the AMD studies in the initial marketing authorization application or the CRVO studies in the first supplemental authorization application.

Based on the week 52 / week 100 results and the favorable benefit/risk balance, Eylea was approved in the US (JUL 2014) and EU (AUG 2014) for the indication DME.

**EYLEA<sup>®</sup>**  
(Aflibercept)  
EU Risk Management Plan

**Part II – Module SIII: Clinical Trial Exposure**

---

Two further completed DME studies are considered in this RMP version for the calculation of exposure and the assessment of safety of Eylea in DME patients: VIVID-JAPAN (SN: 15657) was an open-label, single-arm Phase III study in 72 evaluable Japanese DME patients, who were treated with Eylea 2Q8 after 5 initial doses at monthly intervals through Week 48. The other study, VIVID-EAST (SN 15161), was a randomized controlled Phase III study over one year in mostly Asian patients with the same design as in the first year of the pivotal Phase III studies (VIVID-DME and VISTA-DME). In both studies, the safety and efficacy results at Week 52 were generally consistent with those observed after one year in the pivotal Phase III studies.

## **SIII.2 Clinical Trial Exposure**

### **SIII.2.1 Introduction and overview of studies considered for the calculation of exposure**

Clinical trial exposure showing the overall number of patients by study, by treatment duration, dose, number of injections, demographics, age, gender, ethnicity, and special populations are shown in [Table SIII.1](#) through [Table SIII.33](#). The overall clinical exposure includes data from treated subjects in 9 Phase I-IV studies in wet AMD, 2 Phase III studies in CRVO, the single BRVO Phase III study, the single Phase III study in myopic CNV, and 6 Phase I-III studies in DME.

Exposure data in special populations are exclusively shown for the 2 pivotal randomized Phase III wet AMD studies (VIEW 1 and 2), the 2 Phase III CRVO studies (GALILEO and COPERNICUS), the Phase III BRVO study (VIBRANT), the Phase III trial in myopic CNV (MYRROR), and the 2 controlled Phase III DME studies (VIVID-DME and VISTA-DME).

A summary of patient exposure to Eylea IVT injections for wet AMD, CRVO, BRVO, myopic CNV, and DME in the various clinical trials is provided in [Table SIII.1](#). This table includes the number of patients who switched from one dose to another one within the same study according to protocol, or with enrollment into a follow-up long-term safety study (i.e., VGFT-OD-0702).

In the 9 Phase I-IV wet AMD studies, 2 Phase III CRVO studies, one Phase III BRVO study, one Phase III myopic CNV study, and 6 Phase I-III DME studies, a total of 8,455 patients have been enrolled; with 4,635 thereof having received Eylea injections at various doses of  $\leq 1$  mg, 2 mg, or 4 mg (see [Table SIII.1](#)). For this clinical trial exposure overview, the wet AMD Phase I-II studies, final 96 weeks data from the VIEW 1 and 2 studies, the final data from the VIEW 1 extension study VGFT-OD-0910, the final data from the completed Phase I/II extension study VGFT-OD-0702 as well as the final 1-year data from the completed SIGHT study<sup>4</sup> were considered. For CRVO, the final 76 and 100 weeks data from the Phase III CRVO studies (GALILEO and COPERNICUS trials, respectively) were considered. For BRVO, the final study data of VIBRANT up to Week 52 are included. The myopic CNV indication is represented by final 48 weeks data of the Phase III MYRROR study. For DME, final data of the following studies are considered: Phase I study VGFT-OD-0512, Phase II

---

<sup>4</sup> Please note that the SIGHT study, which is included in the calculation of clinical trial exposure, is not part of the EU submission as it solely relates to Chinese patients with AMD.

EU Risk Management Plan

**Part II – Module SIII: Clinical Trial Exposure**

---

study DAVINCI, single-arm, open-label Phase III study VIVID-JAPAN, pivotal Phase III studies VIVID-DME and VISTA-DME, and Phase III study VIVID-EAST.

### **SIII.2.1.1 Brief description of wet AMD studies**

A total of 5,263 patients were enrolled and 2,672 patients exposed to Eylea in the Phase I-IV wet AMD studies (see [Table SIII.1](#)):

VGFT-OD-0502 was a Phase I study, with 3 parts (A, B and C), of single IVT injections of up to 4 mg of Eylea in patients with wet AMD (12-week active observation, 1 year follow-up).

VGFT-OD-0508 (CLEAR-IT) was a Phase II study of repeated IVT injections of doses of up to 4 mg per injection in patients with wet AMD (12-week fixed dosing every 4 weeks (Q4) or Q12, followed by 52 weeks with dosing as needed).

VGFT-OD-0603 was a Phase I study of repeated IVT injections of 4 mg per dose in patients with wet AMD (8 weeks for first 3 doses, up to 9 months, if treatment was required thereafter).

VGFT-OD-0605 (VIEW 1) was a randomized, controlled Phase III study of repeated IVT injections of 0.5 mg and 2 mg Eylea versus ranibizumab for 2 years in patients with wet AMD.

VGFT-OD-0910 [SN 14832] was an open-label extension study (sponsored by Regeneron Pharmaceuticals, Inc.) subsequent to VIEW 1 in order to enable patients who had completed 2 years of treatment in VIEW 1 to continue (or to initiate) therapy with Eylea 2 mg, for an additional mean treatment duration of approximately 110 weeks. A total of 320 patients completed VIEW 1 and were subsequently treated with Eylea in the study eye (2 mg at individual intervals ranging from 4 to 12 weeks) during the extension study (69 patients from the former ranibizumab group and 87/92/72 patients from the former Eylea 0.5Q4/2Q4/2Q8 treatment groups). Three subjects enrolled in the VIEW 1 extension study received Eylea 2 mg at Week 96 in the original VIEW 1 study (not counted for the VIEW 1 study exposure) but did not receive further treatment in the extension study. These 3 patients are considered for the safety analyses in the VIEW 1 extension study (increased SAF: 323, i.e., 69 and 87/95/72 per treatment group), and the 3 active injections at Week 96 are considered for the calculation of the AMD and overall exposure across studies. Exposure data from VIEW 1 and the extension study were pooled for the description of exposure in VIEW 1 (see [Table SIII.1](#)).

311523/91689 (VIEW 2) was a randomized, controlled Phase III study of repeated IVT injections of 0.5 mg and 2 mg Eylea versus ranibizumab for 2 years in patients with wet AMD.

VGFT-OD-0702 was a randomized, single-masked, long-term, safety, and tolerability study of IVT Eylea in Subjects with wet AMD. Subjects enrolled in the original studies VGFT-OD-0502, VGFT-OD-0508, or VGFT-OD-00603 continued to receive Eylea in this study with a follow up period of up to 3 years. A total of 157 patients were enrolled and 149 patients randomized (50 to the vial group and 99 to the PFS group). Patients in study VGFT-OD-0702 are counted once for the exposure tables below and are included in exposure data of their initial study assignment.

**EYLEA<sup>®</sup>**  
(Aflibercept)  
EU Risk Management Plan

**Part II – Module III: Clinical Trial Exposure**

---

SIGHT (SN 13406) was a randomized, double-masked, photodynamic therapy-controlled Phase III study of the efficacy, safety, and tolerability of VEGF Trap-Eye in Chinese subjects with wet AMD. The primary endpoint (mean change in BCVA) was assessed at 28 weeks, while the study had a total follow-up of 52 weeks. The study had 2 treatment arms. Patients in the Eylea arm were treated with 2 mg Eylea every 4 weeks for the first 3 months, thereafter every 8 weeks until the end of the trial. Subjects in the PDT group underwent one PDT procedure at Baseline and then additional procedures as indicated according to local clinical practice and the clinical judgment of the investigator. These subjects crossed over to active VEGF Trap-Eye treatment after the primary efficacy assessments at Week 28. Thus, the Eylea exposure is calculated based on the 229 patients initially randomized to Eylea plus 70 patients of the original PDT group who were switched to Eylea after Week 28 (i.e., 299 patients in total).

ALTAIR (SN 17668) was a randomized, open-label phase IV study evaluating the efficacy and safety of repeated doses of intravitreal aflibercept with variable treatment intervals in Japanese subjects with wet AMD for up to 2 years. The Treat and Extend regimen was a dosing strategy where the injection interval could be gradually extended as long as functional and anatomic stability of a patient was maintained. The interval could also be shortened if the physician saw deterioration of the patient's condition. After a run-in phase consisting of 3 monthly doses and a 4<sup>th</sup> dose given after 8 weeks, 247 patients were randomly assigned to one of the two treatment arms of the study. Depending on various adjustment criteria, the dose regimen was shortened or extended per individual patient for 2 or 4 weeks (124 subjects in the 2-week [2W] adjustment group, 123 subjects in the 4-week [4W] adjustment group, and 7 subjects failed to be randomized). The 1-year data from both of these groups are considered for this RMP version. The ALTAIR study can help guide physicians in optimizing individual treatment while minimizing over- and under-treatment.

All data concerned with wet AMD utilized in this RMP (other than in this exposure module) are mainly based on the final global integrated analysis of the final 96 weeks dataset of the VIEW 1 and 2 studies; safety results from the VIEW 1 extension study VGFT-OD-0910 as well as from SIGHT and ALTAIR are reported separately.

### **III.2.1.2 Brief description of CRVO studies**

During the 76/100 weeks duration of the 2 Phase III CRVO studies, a total of 513 patients were enrolled, of these, 317 patients received Eylea injections (see [Table III.1](#)).

VGFT-OD-0819 (COPERNICUS) was a randomized, double masked, controlled Phase III study of the efficacy, safety, and tolerability of repeated IVT administration of Eylea in subjects with macular edema secondary to CRVO. In the first 6-months, subjects received either 2 mg Eylea every 4 weeks (Eylea 2Q4) for 20 weeks, or sham injections every 4 weeks for 20 weeks. In the second 6-month period (Week 24 through Week 52), subjects were evaluated every 4 weeks and received either Eylea 2 mg injections or sham injections in accordance with protocol-defined re-treatment criteria. Thus, patients randomized to only receive sham through Week 20 were able to receive active Eylea 2 mg injections from Week 24 to Week 52 if they met re-treatment criteria. In COPERNICUS, starting at Week 52, all subjects were eligible to receive treatment with Eylea to Week 100 in an unmasked 1-year extension phase comprising "as-needed" (PRN) treatment. In this phase of the study, subjects were evaluated quarterly (i.e., every 3 months) and received 2 mg Eylea IVT according to the study re-treatment criteria. No sham injections were performed during this phase.

**EYLEA<sup>®</sup>**  
(Aflibercept)  
EU Risk Management Plan

**Part II – Module SIII: Clinical Trial Exposure**

---

14130 (GALILEO) was a randomized, double-masked, sham-controlled Phase III study of the efficacy, safety, and tolerability of repeated IVT administration of Eylea in subjects with macular edema secondary to CRVO. In the first 6-months, subjects received either 2 mg Eylea every 4 weeks (Eylea 2Q4) for 20 weeks, or sham injections every 4 weeks for 20 weeks. Starting Week 24 through Week 52, subjects in the Eylea group received either Eylea 2 mg injections or sham injections according to protocol-defined re-treatment criteria, while subjects in the sham group continued to receive only sham injections until Week 52. In GALILEO, starting at Week 52, all subjects were eligible to receive treatment with Eylea/sham to Week 76 in a masked 6-month PRN extension phase. In this phase of the study, subjects were evaluated every 8 weeks and received either 2 mg Eylea IVT or sham injections according to the study re-treatment criteria.

In this RMP version, the final data up to Week 76 (GALILEO) and Week 100 (COPERNICUS) from both of the above CRVO studies is included.

### **SIII.2.1.3 Brief description of BRVO study**

VIBRANT (SN 15432, VGFTe RVO-1027) was a randomized, double-masked, active controlled 52-week study to investigate the efficacy, safety, and tolerability of repeated IVT administration of Eylea compared with grid laser photocoagulation in subjects with macular edema secondary to BRVO. Macular grid laser photocoagulation was chosen as comparator treatment, because at the time of inception of VIBRANT in 2012 it could be regarded as representative standard of care treatment in macular edema secondary to BRVO. A total of 183 patients (281 enrolled) were randomized: 91 patients to treatment with Eylea and 92 patients to treatment with laser (see [Table SIII.1](#)). Study treatment in the 2 treatment arms was scheduled as follows:

**Eylea arm:** Patients received Eylea 2 mg every 4 weeks (2Q4) through (including) Week 24, then every 8 weeks (2Q8) through Week 48. Sham IVT injections were administered every 8 weeks starting from Week 28, alternating with Eylea injections every 8 weeks, through Week 44. The last active injection with Eylea was on Week 48. Patients in the Eylea group also received one sham laser treatment on Day 1. Rescue treatment with active laser in this group was possible, if patients meet the pre-defined laser rescue treatment criteria at Week 36.

**Laser arm:** Patients received grid laser photocoagulation treatment at Day 1, and sham IVT injections every 4 weeks from Day 1 through Week 48. Rescue treatment with laser was possible from Week 12 onwards (minimum intervals of 12 weeks from previous laser treatment) in those patients who met the pre-specified rescue treatment criteria. Patients in the laser arm became generally eligible for rescue treatment with Eylea beginning at Week 24. This rescue treatment had to be started with 3 initial active injections every 4 weeks, followed by 2 mg injections every 8 weeks.

In this RMP version, the final study data up to Week 52 (last active treatment on Week 48) are included. A total of 67 patients randomized to the laser arm additionally received rescue treatment with Eylea from Week 24 onwards, thus a total of 158 patients were exposed to Eylea in the VIBRANT study.

### **SIII.2.1.4 Brief description of myopic CNV study**

Study No. 15170 (MYRROR) was a Phase III, multicenter, randomized, double-masked, sham-controlled study of the efficacy, safety, and tolerability of Eylea in patients with

**EYLEA<sup>®</sup>**  
(Aflibercept)  
EU Risk Management Plan

**Part II – Module SIII: Clinical Trial Exposure**

---

choroidal neovascularization secondary to pathologic myopia. In the first 24-week period of the study, patients received either one mandatory 2 mg Eylea IVT injection at Baseline followed by sham injections every 4 weeks, which could be replaced by additional active injections in case of recurring or persisting CNV, or sham injections every 4 weeks only. In the next study period (Week 24 through Week 44), patients in both treatment arms (i.e., incl. patients in the sham group) were allowed to receive Eylea treatment in case of recurring or persisting CNV. Initially, all patients in the sham group received one mandatory active injection at Week 24. Patients continued to be evaluated monthly until Week 48 (the last active injection could be administered at Week 44). Overall, a total of 122 patients were randomized; of these, 91 received Eylea injections before completion of the primary endpoint assessment at Week 24, while 31 patients were randomized to sham treatment. 25 original sham patients actually received at least one active injection with Eylea at Week 24, thus the number of patients exposed to Eylea in the MYRROR study accumulated to 116 patients in total (see [Table SIII.1](#)).

In this RMP version, the final study data through Week 48 are presented.

### **SIII.2.1.5 Brief description of DME studies**

A total of 2,225 patients were enrolled and 1,372 patients exposed to Eylea in the DME studies (see [Table SIII.1](#)).

VGFT-OD-0512 (SN: 14805) was a Phase I, single dose study to assess the safety and tolerability of IVT administered VEGF Trap-Eye in 5 patients with DME, who were exposed to a single 4 mg IVT dose of VEGF Trap-Eye.

VGFT-OD-0706 (DA VINCI; SN: 13336) was a randomized, double-masked, controlled Phase II study of the safety, tolerability, and biological effect of repeated IVT administration of VEGF Trap-Eye in subjects with DME with central involvement, and a BCVA of 20/40 to 20/320 (letter score of 73 to 24). A total of 221 patients were enrolled and 219 treated in the United States, Canada, and Austria. End of treatment was at Week 52 (followed by a safety observation phase up to Week 76). Subjects were randomized to 1 of the following 5 treatment groups:

- VEGF Trap-Eye 0.5 mg every 4 weeks (0.5q4) to week 52,
- VEGF Trap-Eye 2 mg every 4 weeks (2q4) to week 52,
- VEGF Trap-Eye 2 mg every 8 weeks (2q8) after 3 monthly loading doses, with sham injections at alternating visits, to week 52,
- VEGF Trap-Eye 2 mg PRN after 3 monthly loading doses, according to the VEGF Trap-Eye re-treatment criteria, with sham injections at visits at which VEGF Trap-Eye re-treatment criteria were not met, and
- Laser photocoagulation, using the modified ETDRS technique at week 1, and 1 week after visits at which patients met laser re-treatment criteria, to week 52; sham injections every 4 weeks at each study visit; laser re-treatment was permitted no more than once every 16 weeks  $\pm$  3 days.

VGFT-OD-1009 (VISTA-DME) was a 3-year, randomized, double-masked, active-controlled, multicenter Phase III clinical trial of the efficacy and safety of repeated doses of IVT VEGF Trap-Eye in subjects with DME with central involvement, and a BCVA of 20/40 to 20/320

**EYLEA<sup>®</sup>**  
(Aflibercept)  
EU Risk Management Plan

**Part II – Module III: Clinical Trial Exposure**

---

(letter score of 73 to 24). In VISTA-DME, a total of 461 subjects (SAF) were treated in the US.<sup>5</sup>

BAY 86-5321/91745 (VIVID-DME) was a 3-year, randomized, double-masked, active-controlled, multicenter Phase III clinical trial of the efficacy and safety of repeated doses of IVT VEGF Trap-Eye in subjects with DME with central involvement, and a BCVA of 20/40 to 20/320 (letter score of 73 to 24). In VIVID-DME, a total of 404 subjects (SAF) were treated in European countries, Australia, and Japan. VISTA-DME and VIVID-DME had nearly identical overall study designs and are described together, unless otherwise indicated. Patients in either study were randomized to 1 of the following 3 treatment groups:

- VEGF Trap-Eye 2 mg every 4 weeks (2Q4) to Week 144,
- VEGF Trap-Eye 2 mg every 8 weeks (2Q8) after 5 monthly loading doses, with sham injections at alternating visits, to Week 144,
- Laser photocoagulation through week 144.

Subjects in the VEGF Trap-Eye groups received sham laser at baseline and at visits at which subjects met the criteria for laser re-treatment (no more often than every 12 weeks). Subjects in all groups were assessed for additional treatment (i.e., VEGF Trap-Eye for the laser subjects and laser for the VEGF Trap-Eye subjects) for inadequate responders at each visit starting with week 24. Additional treatment was to be administered if either of the criteria were met:

- A loss of  $\geq 15$  letters from the best previous BCVA score due to DME with current BCVA score not better than baseline,
- A loss of  $\geq 10$  letters at 2 consecutive visits at least 7 days apart from the best previous BCVA score due to DME with current BCVA score not better than baseline.

During Year 3, subjects randomized to the laser group who did not meet the criteria for additional treatment previously could receive VEGF Trap-Eye as needed (PRN) according to the VEGF Trap Eye re-treatment criteria from Week 100 to Week 144. The primary efficacy endpoint in both studies was the change in ETDRS letter score from baseline to week 52. Efficacy (visual function) was assessed using the ETDRS protocol at 4 meters at each study visit. Other measures of efficacy included change in CRT as measured by OCT, improvement in ETDRS Diabetic Retinopathy Severity Scale (DRSS) using fundus photography and fluorescein angiography (FA), and questionnaires to examine vision-related quality of life. Overall safety was assessed by monitoring/evaluation of treatment emergent adverse events (TEAEs), physical examinations, electrocardiograms, vital signs, and clinical safety laboratory tests. Ocular safety was assessed by ophthalmic examinations (slit lamp biomicroscopy, indirect ophthalmoscopy, intraocular pressure, OCT), and FP and FA. Last study assessment was on Week 148.

---

<sup>5</sup> As per amendment No. 4, patients completing Visit 39 (Week 148) in VISTA-DME were allowed to receive further treatment extension with Eylea until the planned date for the last on-study patient to complete Visit 39 (November 2014) in order to avoid a potential treatment gap between study end and availability of commercial Eylea. However, the exposure and safety analyses in VISTA-DME are aligned with VIVID-DME and thus limited to the last core study visit (i.e., Week 148).

**EYLEA<sup>®</sup>**  
(Aflibercept)  
EU Risk Management Plan

**Part II – Module SIII: Clinical Trial Exposure**

Fellow eye treatment for DME with anti-VEGF agents was allowed in both Phase III studies. In VIVID-DME, standard of care was used (including ranibizumab or bevacizumab; licensed treatment preferred). In VISTA DME, VEGF Trap-Eye was provided and required as fellow eye treatment; (although ranibizumab could be used. used if VEGF Trap-Eye was unavailable due to logistical reasons).

BAY 86-5321/15161 (VIVID-EAST) was designed similarly to VIVID-DME and VISTA-DME and was conducted in 25 centers in China, Hong Kong, Republic of Korea, and the Russian Federation. Eligible patients were randomized to the laser group (N=124), the Eylea 2Q4 group (N=127), or the Eylea 2Q8 group (N=127). Patients in the laser group were treated with laser photocoagulation at baseline and from week 12 onwards, if laser-re-treatment criteria were met. Patients in the Eylea 2Q4 group received Eylea 2 mg at monthly intervals continuously through Week 48, and patients in the Eylea 2Q8 group received Eylea 2 mg every 2 months following 5 initial injections at monthly intervals (i.e., from Baseline to including Week 16) through Week 48. Additional treatment (with Eylea in the laser group or with laser in the Eylea groups) was permitted from Week 24 onwards. The final study assessments were performed at Week 52.

BAY 86-5321/15657 (VIVID-JAPAN) was an open-label, Phase III study evaluating the safety and tolerability of repeated doses of IVT VEGF Trap-Eye in 73 Japanese patients with DME (SAF: 72 patients, since one treated patient withdrew informed consent and thus was excluded from the SAF). As with the randomized Phase III studies in the 2Q8 group, all patients in VIVID-JAPAN were treated in an open-label fashion with Eylea every 2 months (2Q8) after 5 initial doses at monthly intervals (i.e., 2Q4 up to Week 16). Last treatment was on Week 48; the final endpoint assessments were performed at Week 52. No additional treatment of the study eye with laser was permitted. Fellow eye treatment was allowed as per local standard of care/medical routine. Systemic concentrations of free and bound VEGF Trap were measured at pre-defined time points during the study period.

In this RMP version, the exposure data of the aforementioned 6 Phase I-III studies are used for the description of clinical trial exposure. Safety data in DME are primarily derived from the pooled data set of the pivotal studies VIVID-DME and VISTA-DME through Week 148, while complementary safety results from VIVID-JAPAN and VIVID-EAST are described separately.

### SIII.2.2 Tabulated overview of exposure across of all studies

Considering the 4,635 subjects who had received at least one dose of Eylea in all wet AMD, CRVO, BRVO, myopic CNV, and DME studies, the clinical trial exposure was as displayed in [Table SIII.1](#).

### SIII.2.3 Duration of exposure (patient months)

#### SIII.2.3.1 Indication: Wet AMD

Subject exposure per treatment duration as well as the total cumulative exposure (expressed as patient months) is shown for the wet AMD indication in [Table SIII.2](#). The actual minimum dose applied per single injection was 0.5 mg (shown as ≤1 mg), and the maximum dose was 4 mg. Total exposure for all wet AMD subjects was 55,787 patient months.

### SIII.2.3.4 Indication: Myopic CNV

The final patient exposure per treatment duration as well as the total exposure in months is shown for the myopic CNV indication (MYRROR) through Week 48 in [Table SIII.5](#). A total of 25 patients in the sham group received at least one active Eylea injection from Week 24 onwards; the exposure, however, was less extensive than in the Eylea 2 mg group, since the potential treatment duration was shorter. Overall, a total of 116 patients were exposed to Eylea in the MYRROR study through Week 48 and the cumulative exposure duration was 1,079 patient months.

## SIII.2.4 Number of active injections

### SIII.2.4.1 Indication: Wet AMD

A total of 36,525 Eylea injections were administered to a total of 2,672 wet AMD subjects (see [Table SIII.8](#)).

### SIII.2.4.3 Indication: BRVO

A total of 1,115 active Eylea injections were administered to the 158 patients exposed to Eylea (91 patients in the original Eylea 2 mg group and, now additionally including, 67 patients randomized to the Laser+Eylea 2 mg group who had received 295 active injections from Week 24 onwards). The maximum number of injections in the studied period was 10 injections as defined per study protocol for the study's fixed dose regimen in the Eylea group (see [Table SIII.10](#)).

#### SIII.2.4.4 Indication: Myopic CNV

By Week 48, the 91 patients randomized to the Eylea group in the myopic CNV study MYRROR have received a total of 380 active injections, while 25 of the 31 patients randomized to the Sham+Eylea 2 mg group were treated with a sum of 94 active injections (see [Table SIII.11](#)). Overall, the 116 patients exposed to Eylea were treated with  $4.1 \pm 2.8$  injections on average; the maximum possible number per patient was 12 injections (Baseline through Week 44 at monthly intervals).

### SIII.2.4.5 Indication: DME

The 1,372 subjects who were treated with at least one active injection with Eylea in the 6 DME studies have received a total of 21,711 active injections, with a mean number of  $15.8 \pm 10.3$  injections (see [Table SIII.12](#)).

### SIII.2.5 Duration of exposure (in patient months) by age, sex, and ethnicity

#### SIII.2.5.1 Indication: Wet AMD

Table SIII.14 presents the allocation to treatment groups of all subjects who were included in the Phase I-IV AMD trials, separated by sex, age category, and race.

Generally, there were slightly more female than male subjects treated with Eylea (52.6% vs. 47.4%). As there were more studies performed in the EU and in the USA than in other countries, the majority of subjects in all dose groups receiving Eylea injection were White (68.6%), followed by Asians (28.6%). The majority of subjects receiving Eylea injections were ≥75 years of age in all dose groups (57.1%), followed by the age group ≥65 to <75 years of age (28.1%).

Overall, the subgroup analyses did not point to a specific risk on treatment with Eylea in any of the analyzed subgroups.

### SIII.2.5.2 Indication: CRVO

[Table SIII.16](#) presents the subjects who were treated with Eylea in the 2 Phase III CRVO trials, separated by sex, age category, and race.

Slightly more men than women were included in the Eylea total group (56.5% vs. 43.5%). As seen in the wet AMD studies, the majority of subjects treated with Eylea were White (76.0%). In contrast to the more age-related condition of wet AMD, the CRVO subjects treated with Eylea were obviously younger than wet AMD subjects: Almost half of the subjects in the Eylea total group (45.7%) were younger than 65 years (wet AMD: 10.4%), whilst 21.5% were at the age of 75 years or older (wet AMD: 63.6%).

Again, no specific risk regarding Eylea injection was identified for CRVO subjects in any of the analyzed subgroup.

\*: Calculated by author based on the "sex by age" results

Integrated Analysis Pool 3 RMP: AMD (up to year 3) + CRVO (w76/100) + BRVO (1y) + mCNV (w48) + DME (3y); Table 1.2/4b

An additional analysis was run to determine the age distribution among the 156 women who participated in the 2 CRVO studies (additionally including 204 males [mean age: 63.6 ± 14.7 years], 360 study subjects in total). Applying a threshold age of <55 years, a total of 23 women (14.7% of the 156 enrolled women) seemed to have been of childbearing potential in the CRVO studies (see [Table SIII.18](#)).

### SIII.2.5.3 Indication: BRVO

Table SIII.19 presents the 158 subjects who were treated with Eylea in the Phase III BRVO study VIBRANT separated by sex, age category, and race.

The proportions of men and women treated with Eylea were similar, 44.9% of patients were younger than 65 years, and 73.4% were White. Generally, the BRVO patient characteristics were similar to those observed in the CRVO population.

No specific risk regarding Eylea injection was identified for BRVO subjects in any of the analyzed subgroup.

### SIII.2.5.4 Indication: Myopic CNV

Table SIII.21 shows the MYRROR study patients separated by sex, age category, and race. All enrolled patients in this study were Asians, and clearly more females than males were treated in the Eylea total group (75.0% vs. 25.0%). In this indication - and in contrast to wet AMD or CRVO, where less than half of the patients were <65 years of age -, the majority of patients were younger than 65 years (65.5%), while only 9.5% were 75 years or older in the Eylea total group.

No specific risks associated with Eylea were identified in any of the analyzed subgroups through study end at Week 48.

**Table SIII.21: Number of patients treated with Eylea by sex, age, and race in the myopic CNV Phase III study (SAF)**

Also, in the myopic CNV population the proportion of females of childbearing potential was evaluated (see [Table SIII.23](#)). Given the same age threshold as used for the CRVO population to assume a childbearing potential (i.e., <55 years), a total of 30 women (32.6%) of the 92 females enrolled in MYRROR were of childbearing potential in the myopic CNV study. This proportion was about twice as high as in the CRVO studies.

### SIII.2.5.5 Indication: DME

Table SIII.24 shows the 1,372 subjects, who were treated with Eylea in the Phase I-III DME studies separated by sex, age category, and race. The majority of exposed DME subjects were White (62.7%), and slightly more men than women were included (56.2% vs. 43.8%). 59.5% of the DME subjects were <65 years of age, while 7.7% were 75 years or older.

So far, no specific risk associated with Eylea has been identified for DME in any of the analyzed subgroups.

### SIII.2.6 Exposure in special populations

Data on special populations are shown for the 2 Phase III wet AMD studies (VIEW 1 and 2), the 2 Phase III CRVO studies (GALILEO and COPERNICUS), the Phase III BRVO study (VIBRANT), the Phase III myopic CNV study (MYRROR), and the pivotal Phase III DME studies VIVID-DME and VISTA-DME. This subsection presents the number of subjects by dose group (treatment group) and special population subgroup in order to provide an overview of the distribution of the exposed study subjects among the pre-defined subgroups.

Generally, 6 special population subgroups were identified by medical history, i.e., diabetes mellitus, hypertension, cerebrovascular disease (e.g., CVA/stroke), ischemic heart disease (e.g., myocardial infarction), history of renal impairment, and history of hepatic impairment. The percentages are related to the number of patients who received the respective dose of Eylea in the respective Phase III studies.

#### SIII.2.6.1 Indication: Wet AMD

As regards the wet AMD indication, a total of 1,824 patients with exposure to Eylea constituted the 96 weeks-safety population in the 2 pivotal Phase III studies in wet AMD (VIEW 1 and VIEW 2). [Table SIII.29](#) shows the number of patients with a medical history of diabetes mellitus, hypertension, cerebrovascular disease (e.g., CVA/stroke), ischemic heart disease (e.g., myocardial infarction), hepatic and renal impairment by dose group. There were

**EYLEA<sup>®</sup>**  
(Aflibercept)

Arterial hypertension	320 (52.2)	352 (58.6)	340 (55.7)	1,012 (55.5)
Cerebrovascular disease (e.g., CVA/stroke)	44 (7.2)	62 (10.3)	39 (6.4)	145 (7.9)
Ischemic heart disease (e.g., myocardial infarction)	98 (16.0)	104 (17.3)	112 (18.4)	314 (17.2)

Mild renal impairment: creatinine clearance >50 to 80 mL/min.

Moderate renal impairment: creatinine clearance >30 to 50 mL/min.

Severe renal impairment: creatinine clearance ≤30 mL/min, or requirement for dialysis.

Source: Integrated Analysis – Pool 1, 96 weeks analysis, RMP Exposure, Table 1.1/2a (selected subgroups)

### SIII.2.6.2 Indication: CRVO

A total of 317 subjects constituted the pooled Phase III CRVO safety population exposed to Eylea (either from the beginning or following sham treatment). [Table SIII.30](#) shows the number of patients with a medical history of diabetes mellitus, hypertension, cerebrovascular disease (e.g., CVA/stroke), ischemic heart disease (e.g., myocardial infarction), hepatic and renal impairment by dose groups. There were no significant safety issues revealed during exposure of special populations to Eylea injections in the CRVO Phase III studies.

Mild renal impairment: creatinine clearance >50 to 80 mL/min.

Moderate renal impairment: creatinine clearance >30 to 50 mL/min.

Severe renal impairment: creatinine clearance ≤30 mL/min, or requirement for dialysis.

\*: Sham (without or before 1st PRN): includes all subjects receiving at least one sham injection and considers time period up to 1st active PRN injection.

\*\* : PRN (following sham, after 1st PRN): includes all subjects receiving at least one active PRN injection and considers time period from 1st active PRN injection onwards. All subjects of PRN (following sham, after 1st PRN) group are also included in Sham (without or before 1st PRN) group, but with a different observation period.

\*\*\*: Eylea total: Eylea 2Q4 + PRN and PRN (following sham, after 1st PRN) combined.

Source: Integrated Analysis – Pool 1 CRVO, RMP, Table 1.1/2

### SIII.2.6.3 Indication: BRVO

The BRVO safety population consisted of 183 patients, with 158 patients exposed to Eylea. [Table SIII.31](#) shows the number of patients with a medical history of diabetes mellitus, hypertension, cerebrovascular disease (e.g., CVA/stroke), ischemic heart disease (e.g., myocardial infarction), hepatic and renal impairment by randomized treatment group. Generally, there were no significant safety issues revealed during the exposure of special populations to Eylea injections in the BRVO Phase III study.

**Table SIII.31: Clinical trial exposure by special populations in the pivotal BRVO Phase III study (SAF)**

Severe renal impairment	0	0	0
Hepatic impairment	0	8 (8.8)	8 (6.9)
Diabetes mellitus	1 (3.2)	6 (6.6)	7 (6.0)
Arterial hypertension	5 (16.1)	29 (31.9)	33 (28.4)
Cerebrovascular disease (e.g., CVA/stroke)	1 (3.2)	4 (4.4)	5 (4.3)
Ischemic heart disease (e.g., myocardial infarction)	0	4 (4.4)	4 (3.4)

Mild renal impairment: creatinine clearance >50 to 80 mL/min.

Moderate renal impairment: creatinine clearance >30 to 50 mL/min.

Severe renal impairment: creatinine clearance ≤30 mL/min, or requirement for dialysis

Source: Integrated Analysis Pool 1 mCNV (48 weeks), Table 1.2/2c

### SIII.2.6.5 Indication: DME

Table SIII.33 shows the number of subjects with a medical history of hypertension, cerebrovascular disease (e.g., CVA/stroke), ischemic heart disease (e.g., myocardial infarction), hepatic and renal impairment in the DME subjects enrolled in the randomized, controlled Phase III studies VIVID-DME and VISTA-DME. Inherently, all enrolled patients suffered from diabetes mellitus. By Week 148, there were no significant safety issues observed during exposure of special populations to Eylea injections in the DME studies.

### **SIV.3 Limitations in Respect to Populations Typically under-represented in Clinical Trial Development Programmes**

#### **SIV.3.1 Children**

No clinical trials were conducted in children so far. Since the indications wet AMD, CRVO, BRVO, myopic CNV, and DME are disorders which occur mainly in adults or in the elderly, clinical studies in children are not warranted or justified.

#### **SIV.3.2 Elderly**

In the wet AMD studies VIEW 1 and VIEW2, more than half of the patients exposed to Eylea (57.7%) were  $\geq 75$  years old and 27.3% were aged between 65 and 74 years. Therefore, there is a high percentage of elderly in the clinical study program.

More than half of the patients enrolled in both Phase III CRVO studies were  $\geq 65$  years (54.3%). 45.7% of the CRVO patients were below 65 years of age. Mean age of patients at enrollment was 64.0 years, with individual patients' ages ranging from 22 to 89 years.

In the Phase III BRVO study VIBRANT, 44.9% of the 158 Eylea-exposed patients were younger than 65 years, 33.5% were aged between 65 to 74 years, and 21.5% were aged 75 years or older.

In the myopic CNV study, 65.5% of the 116 subjects exposed to Eylea (SAF) were at the age of <65 years, 25.0% were aged between 65 and 74 years, and 9.5% were  $\geq 75$  years.

In the Phase I-III DME studies, 32.7% of the 1,372 subjects exposed to Eylea were at the age of  $\geq 65$  to <75 years, and 7.7% were  $\geq 75$  years. Due to the relatively small number of DME patients aged 75 years or older, a statement was included in the SmPC that there is limited experience in patients older than 75 years with DME.

The distribution of the age groups is summarized by indication and in total in [Table SIV.3](#). Overall, approximately one-third each of all exposed patients (N=4,635) belonged to one of the 3 age groups <65 years (32.4% of patients),  $\geq 65$  to <75 years (29.9%), and  $\geq 75$  years (37.6%).

### SIV.3.3 Pregnant or breast-feeding women

Pregnancy and lactation constituted exclusion criteria in all clinical trials. There are no adequate and well-controlled studies in pregnant women.

So far, 8 cases of pregnancy were reported from clinical studies (direct exposure or exposure through male partner; see [Part II Module SVII, Section SVII.3.1.14](#) and 12 cases of pregnancy in female patients treated in the post-marketing setting until 15 SEP 2017 ([Part II Module SVII, Section SVII.3.1.14](#)). These few cases did not suggest that treatment with Eylea might be associated with relevant embryo-fetotoxic effects.

### SIV.3.4 Patients with a medical history of hepatic impairment

No specific studies have been performed in patients with hepatic disorders.

Patients with hepatic disorders were not excluded in the clinical study program.

After intravitreal administration of a maximum of 2 mg per dose, plasma concentrations of free aflibercept are negligibly low compared with those after subcutaneous and intravenous administration. Concentrations of bound aflibercept were also very low. In addition, the active moiety in aflibercept is a large protein. The metabolism and excretion of such molecules is generally by means other than the renal or hepatic pathways. It was therefore not considered necessary to conduct special clinical studies in patients with hepatic impairment.

No PK analyses were performed in VIEW 1, and no specific PK analysis in patients with a medical history of hepatic impairment was performed in the wet AMD study VIEW 2.

In SIGHT (SN 311523), there were only 4 subjects with a medical history of hepatic impairment compared with 195 subjects with no hepatic impairment, with mean values for free (adjusted bound) VTE of 22.85 (160.25) and 10.69 (147.79) µg/L, respectively. The difference in free VTE was attributed to high variability and the small number of subjects in the hepatic impairment group. Overall, the data did not provide any indication for a clinically relevant difference in free or adjusted bound VTE concentrations detected in subjects with different hepatic impairment status.

**EYLEA<sup>®</sup>**  
(Aflibercept)  
EU Risk Management Plan

**Part II – Module SIV: Populations not studied in Clinical Trials**

---

In the ALTAIR study (SN 17668), 17 subjects had a medical history of hepatic impairment compared to 237 subjects with no hepatic impairment. No pharmacokinetic analyses were performed in the frame of this study.

Pharmacokinetic analysis of patients in the GALILEO study (study 14130, Bayer AG study) at Week 12, revealed no differences with respect to plasma concentrations of active drug after intravitreal administration every 4 weeks. It must be considered that the sub-group of subjects with a medical history of hepatic impairment included only one to two subjects across all weeks. No pharmacokinetic analyses were done in the COPERNICUS study (study run by Regeneron Pharmaceuticals, Inc.).

Pharmacokinetic analysis of patients in the VIBRANT study (study VGFTe-RVO-1027-BA01V1, study run by Regeneron Pharmaceuticals, Inc.) revealed no differences with respect to plasma concentrations of active drug after intravitreal administration every 4 weeks through Week 24 (no PK sampling time points were planned after Week 24). It must be considered that the sub-group of subjects with a medical history of hepatic impairment included only one subject.

Similarly, pharmacokinetic analyses of patients in the myopic CNV study (MYRROR) up to Week 24 showed that the systemic exposure to free and bound VEGF Trap was low. The exploratory sub-group analyses did not reveal any relevant influence of hepatic function on the plasma concentration of adjusted bound VEGF Trap. However, it must be considered that the subgroup of patients with a medical history of hepatic impairment included only 7 patients at Week 12 (compared to 53 without medical history of hepatic impairment) and 5 patients at Week 24 (compared to 27 without a medical history of hepatic impairment). For free VEGF Trap, the concentrations measured for the subgroup analyses were below the limit of quantification, therefore definitive conclusions regarding the effect of the covariate factors on systemic exposures to free VEGF Trap could not be drawn. The final analyses at Week 48 did not result in new or unexpected findings compared to Week 24.

In the VIVID-DME study (SN 91745, Bayer AG study), analysis of patients with a medical history of hepatic impairment at Week 0, Day 2-4, Week 24, and Week 52 revealed no influence of a medical history of hepatic impairment on plasma concentrations of free VEGF Trap. For adjusted bound VEGF Trap, a medical history of hepatic impairment showed a slight trend towards lower plasma concentrations with increasing level of impairment. However, the number of patients with liver dysfunction was very low (n=7) compared to patients without (n=118). In addition, plasma concentration ranges overlapped considerably. Therefore, these differences were not considered to be clinically relevant. No PK analyses were performed after the first year of the study.

No pharmacokinetic analysis was done in the VISTA-DME study (study run by Regeneron Pharmaceuticals, Inc.) or in the VIVID-EAST study (study run by Bayer AG). In the Phase III open-label DME study VIVID-JAPAN, exploratory subgroup analyses revealed no clinically relevant effects on free and bound VEGF Trap plasma concentrations with respect to medical history of hepatic impairment.

### **SIV.3.5 Patients with renal impairment**

No specific studies have been performed in patients with renal disorders. Patients enrolled in the clinical studies were classified according to their baseline creatinine clearance values in one of the 4 groups:

**EYLEA<sup>®</sup>**  
(Aflibercept)  
EU Risk Management Plan

**Part II – Module SIV: Populations not studied in Clinical Trials**

---

- Creatinine clearance >80 mL/min (normal renal function),
- Creatinine clearance >50-80 mL/min (mild renal impairment),
- Creatinine clearance >30-50 mL/min (moderate renal impairment),
- Creatinine clearance ≤30 mL/min or requiring dialysis (severe renal impairment).

No PK analyses were performed in VIEW 1. Pharmacokinetic analysis of patients in the VIEW 2 study, of which 40% had a medical history of renal impairment (24% mild, 15% moderate, and 1% severe), revealed no differences with respect to plasma concentrations of active drug after intravitreal administration every 4 or 8 weeks. After intravitreal administration of a maximum of 2 mg per dose, plasma concentrations of free aflibercept were negligibly low compared with those after subcutaneous and intravenous administration. Concentrations of bound aflibercept were also very low. In addition, the active moiety in aflibercept is a large protein. The metabolism and excretion of such molecules is generally by means other than the renal or hepatic pathways. It was therefore not considered necessary to conduct special clinical studies in patients with renal disorders.

In SIGHT (SN 311523), the number of subjects in each creatinine clearance subgroup decreased from normal and mild renal impairment groups (89 subjects in the >80 mL/min group and 93 subjects in the >50-80 mL/min group) to moderate and severe renal impairment groups (12 subjects in the >30-50 mL/min group, and 1 subject in the ≤30 mL/min group). There was no quantifiable free VTE concentration in the one severe renal impairment subject. Overall, there was no difference in free or adjusted bound VTE concentrations detected in subjects with different renal function.

No PK analyses were performed in the ALTAIR study (SN 17668).

Pharmacokinetic analysis of patients in the GALILEO study (study 14130, Bayer AG study) at Week 12, of which 43% had a medical history of renal impairment (39% mild and 4% moderate), revealed no differences with respect to plasma concentrations of active drug after intravitreal administration every 4 weeks. No pharmacokinetic analyses were done in the COPERNICUS study (study run by Regeneron Pharmaceuticals, Inc.).

Pharmacokinetic analysis of patients in the VIBRANT study (study VGFTe-RVO-1027-BA01V1, study run by Regeneron Pharmaceuticals, Inc.) revealed no differences with respect to plasma concentrations of active drug after intravitreal administration every 4 weeks through Week 24 (no PK sampling time points were planned after Week 24). It must be considered that the sub-group of subjects with a medical history of renal impairment included 3 subjects with moderate (>30-50mL/min) and 11 subjects with mild (>50-80 mL/min) renal impairment.

In the Phase III myopic CNV MYRROR study, 63% of patients treated with VEGF Trap had a medical history of renal impairment (52% mild and 11% moderate; solely defined through baseline creatinine clearance values of >50-80 mL/min and >30-50 mL/min, respectively). Pharmacokinetic analyses of patients in MYRROR up to Week 48 revealed no specific influence of medical history of renal impairment on the pharmacokinetics of bound VEGF Trap.

In the VIVID-DME study (SN: 91745, Bayer AG study), analysis of patients with a medical history of renal impairment at Week 0, Day 2-4, Week 24, and Week 52 revealed no influence of renal impairment on plasma concentrations of free VEGF Trap. For (the pharmacologically

**EYLEA<sup>®</sup>**  
(Aflibercept)  
EU Risk Management Plan

**Part II – Module SIV: Populations not studied in Clinical Trials**

---

inactive) adjusted bound VEGF Trap, a slight trend towards higher plasma concentrations with increasing level of impairment was shown. However, the number of patients with renal dysfunction decreased from more than 60 (>80 mL/min creatinine clearance) to 1 (<30 mL/min creatinine clearance). In addition, plasma concentration ranges overlapped considerably. Therefore, these differences were not considered to be clinically relevant. No further PK samples were taken after the first year of the study.

No pharmacokinetic analysis was done in the VISTA study (study run by Regeneron Pharmaceuticals, Inc.) or in the VIVID-EAST study (study run by Bayer AG).

In the Phase III open-label DME study VIVID-JAPAN, renal function was assessed by calculated  $CL_{CR}$  and divided into 4 subgroups. The mean of free VEGF Trap concentrations slightly increased with decreasing  $CL_{CR}$ . However, taking into account the absolute values, large variability, and very low number of patients in the lowest  $CL_{CR}$  ( $\leq 30$  mL/min) group, these differences appeared to be small and clinically not relevant. For the pharmacologically inactive adjusted bound VEGF Trap, there was no clear trend seen in plasma concentrations across the different  $CL_{CR}$  groups. Subjects in the >80 mL/min  $CL_{CR}$  group had a lower mean compared to subjects with  $CL_{CR}$  values  $\leq 80$  mL/min. However, the ranges of all  $CL_{CR}$  groups overlapped considerably and in 3 out of the 4 groups the maximum concentrations of adjusted bound VEGF Trap did not exceed the LLOQ (lower limit of quantitation) by more than 4.5-fold (except  $CL_{CR}$  >50-80 mL/min group where it exceeded the LLOQ by 19-fold).

**SIV.3.6 Patients with other relevant co-morbidity**

Not applicable.

**SIV.3.7 Patients with a disease severity different from the inclusion criteria in the clinical trial population**

Not applicable.

**SIV.3.8 Sub-populations carrying known and relevant polymorphisms**

Not applicable.

**SIV.3.9 Patients of different racial and/or ethnic origin**

The VIEW 1 and VIEW 2 studies (Phase III wet AMD trials) were conducted in a total of 28 countries including North and South America, Europe and Asia Pacific. Study populations included Caucasian, Asian, Hispanic, and Black patients. The Phase III AMD study SIGHT was performed among 304 Chinese patients.

The Phase III CRVO trial COPERNICUS was conducted at 61 sites in the USA, Canada, Colombia, Israel and India. The GALILEO study was conducted at 63 sites in Europe and the Asia Pacific region.

The Phase III BRVO study VIBRANT was conducted at 58 sites in the USA, Canada, and Japan.

Only Asian patients were randomized and treated in the Phase III myopic CNV study MYRROR (90 patients in Japan and 32 patients in other Asian countries [Taiwan, South Korea, Hong Kong, and Singapore]).

**EYLEA<sup>®</sup>**  
(Aflibercept)  
EU Risk Management Plan

**Part II – Module SIV: Populations not studied in Clinical Trials**

The Phase III DME study VISTA-DME was performed in the USA, while the Phase III DME study VIVID-DME was conducted in various European countries, Japan, and Australia. Only Japanese patients were included in the open-label Phase III DME study VIVID-JAPAN (72 patients in the SAF). In the Phase III DME study VIVID-EAST, most of the patients were enrolled in China (approximately 80%), while the remaining patients were enrolled in Russia and other Asia-Pacific countries.

Overall, patients of various different racial and/or ethnic origins were exposed to Eylea in the development programs; the majority of exposed patients, however, were White (65.8%; see [Table SIV.4](#)).

**Table SIV.4: No. of patients by race in Phase I-III AMD studies, Phase III CRVO studies, Phase III BRVO study, Phase III myopic CNV study, and Phase I-III DME studies (SAF)**

### SIV.3.10 Conclusion on the populations not-studied and other limitations of the clinical trial development programme

As Eylea belongs to the class of anti-VEGF therapies, which are potentially teratogenic, embryo-fetotoxicity has been identified as an important potential risk. “Use of Eylea in breastfeeding women” is included as Missing Information in the list of safety concerns. No additional safety concerns were identified in this section.

**EYLEA<sup>®</sup>**  
(Aflibercept)  
EU Risk Management Plan

**Part II – Module SV: Post-authorisation Experience**

---

**PART II**  
**Module SV: Post-authorisation Experience**

**SV.1 Post-authorisation Exposure**

**SV.1.1 Method used to Calculate Exposure**

The patient exposure displayed in this RMP (expressed as patient years [PYs]) was estimated based on the number of sold/distributed Eylea vials during the reporting period and the presumed underlying prevalence and treatment schedules of the approved Eylea indications wet AMD, CRVO, BRVO and DME. The following assumptions were made:

wet AMD: 52% of Eylea-treated patients will have AMD and receive 7 vials per year,

CRVO: 6% of Eylea-treated patients will have CRVO and receive 6 vials per year,

DME: 26% of Eylea-treated patients will have DME and receive 8 vials per year,

BRVO: 13% of Eylea-treated patients will have BRVO and receive 6 vials per year,

Myopic CNV: 3% of Eylea-treated patients will have myopic CNV and receive 1 vial per year.

The resulting formula for the calculation of total PYs is:

$$\begin{aligned} \text{Total no. of vials} / ((0.52 \times 7) + (0.06 \times 6) + (0.26 \times 8) + (0.13 \times 6) + (0.03 \times 1)) \\ = \text{Total no. of vials} / 6.89 \end{aligned}$$

and the PYs per indication were calculated as 52%, 6%, 26%, 13%, and 3% from the total PYs for wet AMD, CRVO, DME, BRVO, and myopic CNV, respectively.

This mode of calculation for PYs is considered rather conservative, because patients treated under usual care conditions might receive fewer injections than required per label, meaning that the true number of patient years (i.e., number of treated patients) could be even higher than calculated (which would further decrease the estimated incidence rates of post-marketing safety events related to PYs).

**SV.1.2 Exposure**

A total of 15,967,450 vials were sold world-wide by 30 SEP 2017<sup>6</sup>, resulting in an estimated overall exposure of 2,317,482 PYs across all 5 indications based on the aforementioned formula. The exposure by country and by indication is provided in the following table.

## **PART II**

### **Module SVII: Identified and Potential Risks**

#### **SVII.1 Identification of Safety Concerns in the Initial RMP Submission**

*Introductory note: Please note that the contents of the previous Eylea EU-RMP (Version 24.0) have been transferred into the new EU-RMP template. Therefore, this section does not describe the situation at the time of the initial approval of Eylea, as this information is outdated (initial EU approval was on 22 NOV 2012). Instead, both the definitions of safety concerns and the adverse drug reaction table valid at the time of the first drug renewal procedure (EMA/H/C/002392/R/0033) have been used for the current presentation of safety concerns according to the new template. This section will now be locked after RMP approval and any future changes presented in Section SVII.2*

##### **SVII.1.1 Risks not considered important for Inclusion in the List of Safety Concerns in the RMP**

###### **Adverse drug reactions seen in phase III studies**

The following treatment-emergent drug reactions (reported in patients in Eylea Phase III studies) are included in the current SmPC (version JUL 2017, MedDRA preferred term level):

Very common: Visual acuity reduced, conjunctival haemorrhage, eye pain.

Common: Retinal pigment epithelial tear, detachment of retinal pigment epithelium, retinal degeneration, vitreous haemorrhage, cataract, cataract cortical, cataract nuclear, cataract subcapsular, corneal erosion, corneal abrasion, intraocular pressure increased, vision blurred, vitreous floaters, vitreous detachment, injection site pain, foreign body sensation in eyes, lacrimation increased, eyelid oedema, injection site haemorrhage, punctate keratitis, conjunctival hyperaemia, ocular hyperaemia.

Uncommon: Hypersensitivity, endophthalmitis, retinal detachment, retinal tear, iritis, uveitis, iridocyclitis, lenticular opacities, corneal epithelium defect, injection site irritation, abnormal sensation in eye, eyelid irritation, anterior chamber flare, corneal oedema.

Rare: Blindness, cataract traumatic, vitritis, hypopyon.

The conditions, which are regarded as important identified or potential risks (either as single preferred term event term or by term grouping) are underlined in the preceding listing. The remaining risks are not regarded as important for the following reasons A to C:

###### **A) Risks with minimal clinical impact on patients (in relation to the severity of the indication treated):**

- Visual acuity reduced (very common), vision blurred (common).  
*Comment: This functional loss is mainly considered to occur as a result of the underlying ocular disease. It may represent a symptom of an injection related event such as intraocular inflammation/infection or retinal tear/detachment. These complications pose important identified risk in the EU RMP.*
- Conjunctival haemorrhage (very common), conjunctival hyperaemia (common), ocular hyperaemia (common), vitreous haemorrhage (common), vitreous floaters (common), eye pain (very common), injection site pain (common), injection site

**EYLEA®**  
(Aflibercept)  
EU Risk Management Plan

**Part II – Module SVII: Identified and Potential Risks**

---

haemorrhage (common), injection site irritation (uncommon), lacrimation increased (common), foreign body sensation in eyes (common), abnormal sensation in eye (uncommon), eyelid irritation (uncommon).

*Comment: These are local events likely caused by the intraocular injection procedure, which are usually mild and fully reversible in nature. It is expected that HCPs are well familiar with these concomitant adverse effects of the IVT injection.*

**B) Known risks that do not impact the risk-benefit profile (in relation to the severity of the indication treated):**

- Detachment of retinal pigment epithelium (common), retinal degeneration (common), vitreous detachment (common), corneal erosion (common), corneal abrasion (common), punctate keratitis (common), corneal epithelium defect (uncommon).  
*Comment: These events are likely procedure-related (however, “detachment of retinal pigment epithelium” and “retinal degeneration” could also be promoted by underlying disease) and may result in longer-term complaints. However, no severe sequelae are expected, and these events are not assumed to impair the positive risk/benefit profile of Eylea. It is expected that HCPs are well familiar with these potential adverse effects of the IVT injection.*

**C) Adverse reactions with clinical consequences, even serious, but occurring with a low frequency and considered to be acceptable in relation to the severity of the indication treated:**

- Blindness (rare).  
*Comment: This event is rare and may also occur as a result of the underlying disease.*

**Reasons for considering other risks not important (incl. class effects)**

Potential risk: Sustained intraocular pressure.

Issue: A persistent ocular hypertension (OHT) has been observed after intravitreal injection of VEGF inhibitors (ranibizumab, bevacizumab) (155), (156), (137), (157), leading to an assumed class effect of “sustained” IOP increase. The incidence of sustained OHT after intraocular administration of these VEGF inhibitors ranged between 3.1% and 11.9% in studies with 96 - 512 treated eyes (155), (137). Two hypotheses have been described for the underlying mechanism of chronic OHT:

- 1) The anti-VEGF antibodies (= high molecular proteins) may accumulate in the aqueous outflow channels including the trabecular meshwork or Schlemm’s canal and obstruct aqueous outflow (158).
- 2) Immunological reactions and low-grade inflammation postinjection may be an additional mechanism leading to IOP elevations (137), (159).

Both effects may be amplified by the quality of the injected VEGF inhibitor: aggregation of the antibody to higher molecular structures may enhance the obstruction of the outflow system. Also, contaminants such as silicone oil from the syringe barrel or rubber stopper may block the outflow system or induce subclinical inflammation (156), (160), (161).

**EYLEA<sup>®</sup>**  
(Aflibercept)  
EU Risk Management Plan

**Part II – Module SVII: Identified and Potential Risks**

Comment: A transient increase of IOP, which is often observed after intravitreal injection of fluids, is considered an important identified risk of IVT Eylea administration. It is attributed to an increase in vitreous volume (volume effect), which is compensated within 0.5 to 1 hours after injection, so that IOP normalizes back to baseline values (162), (160). Therefore, the volume effect is not responsible for a chronic elevation of IOP. Thorough monitoring of mean values over time for pre-injection IOP in the clinical Phase III Eylea trials indicated there is no trend towards sustained IOP increase on treatment with Eylea. Therefore, the assumed class effect of "sustained" IOP increase is not regarded as an important risk of treatment with Eylea.

**SVII.1.2 Risks considered important for Inclusion in the List of Safety Concerns in the RMP**

An overview of the important identified risks of Eylea is provided in [Table SVII.1](#).

**Table SVII.1: Overview of important identified risks**

Important identified risk	Risk-benefit impact
Endophthalmitis (likely infectious origin)	<p>Endophthalmitis is an intraocular infection and may occur as a result of an infection with microorganisms, either through direct traumatic injury of the eye (exogenous infection) or through spreading of microorganisms from other areas of the body (endogenous infection). In cases of inflammation where no pathogens can be identified (no/negative culture growth of microorganisms observed), the condition may be characterized as "sterile endophthalmitis" or "non-infectious endophthalmitis".</p> <p>Because of the risk of severe vision loss, treatment should be initiated as soon as possible, and, depending on cause and severity, may consist of topical and intravitreal application of antibiotics, corticosteroids, and surgical removal of matter and infected structures (drainage, vitrectomy).</p> <p>The risk of endophthalmitis (and other intraocular infections) cannot be completely excluded but minimized through strict aseptic and sterile conditions when administering Eylea. Only experienced and appropriately trained ophthalmologists should be charged with the injections, and patients should report any signs or symptoms of intraocular inflammation (e.g., visual acuity decreased, pain, photophobia, or redness) as soon as possible in order to enable the treating physician to introduce appropriate countermeasures in due time. Educational material is provided i.a., to promote optimal administration technique.</p> <p>The proportion of Eylea-exposed patients who experienced endophthalmitis in the study eye in the clinical studies with Eylea was low (range from 0% to 0.9% in the VIEW 1 extension study); endophthalmitis is regarded as an uncommon ADR. Endophthalmitis cases (and other cases of intraocular inflammation) reported in post-marketing setting are subject to additional follow-up</p>

**EYLEA<sup>®</sup>**  
(Aflibercept)  
EU Risk Management Plan

**Part II – Module SVII: Identified and Potential Risks**

**Table SVII.1: Overview of important identified risks**

<b>Important identified risk</b>	<b>Risk-benefit impact</b>
Intraocular inflammation	<p>using specific questionnaires. Currently, the risk-benefit in terms of endophthalmitis is considered favorable for Eylea.</p> <p>Intraocular inflammations (other than endophthalmitis) are inflammations of defined structures of the inner eye (e.g., iritis, uveitis, iridocyclitis). Aside from endophthalmitis / intraocular inflammations with an infectious origin, there are also inflammations where no pathogens can be identified (either no culture performed or negative culture growth), the condition may be characterized as "sterile" inflammatory condition.</p> <p>The cause of a sterile inflammation, independently of the administered drug, remains uncertain, and a multifactorial origin cannot be discarded. An intraocular inflammation generally constitutes a serious condition, which may lead to generalized eye inflammation and risk of blindness. Treatment should be initialized as soon as possible, and, depending on cause and severity, may consist of topical and intravitreal application of antibiotics, corticosteroids, and surgical removal of matter and infected structures (drainage, vitrectomy).</p> <p>The risk of intraocular infections can be minimized through strict aseptic and sterile conditions when administering Eylea (see endophthalmitis).</p> <p>The proportion of Eylea-exposed patients who experienced intraocular inflammation (grouped term) in the study eye in the clinical studies with Eylea ranged from 0% to 2.6% (VIEW 1 &amp; 2 AMD studies). Single preferred terms events associated with intraocular inflammation are considered uncommon ADRs (e.g., iritis, uveitis, iridocyclitis) or rate ADRs (vitritis, hypopyon). Endophthalmitis and other cases of intraocular inflammation reported in post-marketing setting are subject to additional follow-up using specific questionnaires. Currently, the risk-benefit in terms of intraocular inflammation is considered favorable for Eylea.</p>
Transient intraocular pressure increase	<p>Chronically elevated intraocular pressure is a major risk factor for a condition called "glaucoma", which is characterized by a loss of nerve fibers in the optic nerve with the subsequent risk of blindness. However, many different factors may be responsible for the development of glaucoma, and increased intraocular pressure is not a mandatory prerequisite for the development of glaucoma (e.g., normal-tension glaucoma). Transient IOP increase following IVT injection is a well-known side effect of any IVT administration of liquids used for drug dissolution, but this condition is limited and usually resolved once the surplus fluid has been resorbed from the inner eye.</p> <p>The proportion of Eylea-exposed patients who</p>

**EYLEA®**  
(Aflibercept)  
EU Risk Management Plan

**Part II – Module SVII: Identified and Potential Risks**

**Table SVII.1: Overview of important identified risks**

<b>Important identified risk</b>	<b>Risk-benefit impact</b>
	<p>experienced an increase in intraocular pressure (grouped term) in the study eye in the clinical studies with Eylea ranged from 2.8% (VIVID-JAPAN DME study) to 13.6% (CRVO studies GALILEO &amp; COPERNICUS), but the vast majority of these events were resolved. Systematic measurements of IOP during the course of the clinical studies did not indicate a trend towards sustained IOP increase. “Intraocular pressure increased” (single preferred term) is considered a common ADR. Transient intraocular pressure increase reported in post-marketing setting are subject to additional follow-up using specific questionnaires (currently under review). Currently, the risk-benefit in terms of transient IOP increase is considered favorable for Eylea.</p>
Retinal pigment epithelial (RPE) tears	<p>The retinal pigment epithelium is the outer layer of the retina, and tears in that layer may occur secondary to AMD, following intravitreal injections, or for unknown reasons. These tears may be self-sealing or may require sealing by laser coagulation.</p> <p>In clinical trials up to 1.9% of patients with underlying wet AMD who were treated with Eylea developed RPE tear, while none of the patients treated for other Eylea indications (CRVO, BRVO, myopic CNV, DME) had developed RPE tear. RPE tear is considered a common ADR. However, the total incidence of RPE tears with Eylea in the AMD Phase III trials was in line with the known background incidences from literature; and the absence of RPE tear in the clinical studies investigating the non-AMD indications of Eylea suggests that RPE tear development caused by IVT treatment with Eylea is rather unlikely. Currently, the risk-benefit in terms of RPE tear is considered favorable for Eylea.</p>
Retinal tear / detachment	<p>Retinal tear / detachment is characterized by separation of the retina from its attachment to the underlying tissues. Most retinal detachments are a result of a retinal break, hole, or tear. Retinal tear / detachment usually constitutes an ophthalmological emergency that requires medical intervention, including sealing and/or re-attachment of the retinal lesion through laser photocoagulation or freezing (cryotherapy).</p> <p>The risk can be reduced by performing a proper IVT injection technique IVT procedure using a correct angle of the needle while injecting.</p> <p>The proportion of Eylea-exposed patients who experienced retinal tear/detachment in the study eye in the clinical studies with Eylea ranged from 0% to 1.5% (VIEW 1 extension study). Retinal tear / detachment is considered an uncommon ADR. Currently, the risk-benefit in terms of retinal tear / detachment is considered favorable for Eylea.</p>

**EYLEA<sup>®</sup>**  
(Aflibercept)  
EU Risk Management Plan

**Part II – Module SVII: Identified and Potential Risks**

**Table SVII.1: Overview of important identified risks**

<b>Important identified risk</b>	<b>Risk-benefit impact</b>
Cataract (especially of traumatic origin)	<p>Cataract (clouding of lens) may occur spontaneously (particularly in the elderly), as a side effect of certain drugs, or following outside influences such as irradiation or mechanical injury (traumatic cataract).</p> <p>Thus, the needle injury required to inject Eylea through the lens into the eyeball could cause such a traumatic cataract. However, by correct IVT procedure and a correct angle of the needle while injecting, the risk of cataract development can be minimized.</p> <p>The proportion of Eylea-exposed patients who experienced traumatic cataract in the study eye in the clinical studies with Eylea ranged from 0% to 2.8% (VIVID-DME &amp; VISTA-DME). Various forms of cataract (cortical, nuclear, subcapsular) are considered common ADRs; traumatic cataract is regarded as a rare ADR.</p> <p>There is currently no evidence that the occurrence of a traumatic cataract is increased on treatment with Eylea. However, as this might be a hypothetical result of the lens perforation, it has been included as important identified risk. Currently, the risk-benefit in terms of cataract development is considered favorable for Eylea.</p>
Hypersensitivity and immunogenicity	<p>VEGF-Trap Eye is a foreign protein to the patient and, as such, may generate allergic reactions or may prompt the immune system to react by formation of specific antibodies, which in turn may cause immunologic reactions or attenuate the drug effects. Therefore, both hypersensitivity and immunogenicity are considered important identified risks of treatment with Eylea. Patients with known hypersensitivity to Eylea or to any of its excipients must not be treated with Eylea.</p> <p>The proportion of Eylea-exposed patients who experienced any potential hypersensitivity events in the clinical studies (grouped term) with Eylea ranged from 0% to 5.2% (VIEW 1 &amp; VIEW 2). Hypersensitivity is considered an uncommon ADR.</p> <p>Since Eylea is injected locally into the eye, the systemic exposure to Eylea is very small. Furthermore, immunogenicity to Eylea appears to be very low and there is no evidence that it impacts the safety or efficacy of Eylea. Currently, the risk-benefit in terms of hypersensitivity / immunogenicity is considered favorable for Eylea.</p>

[Table SVII.2](#) summarizes the identified potential risks of Eylea. This group mainly includes the class effects known from systematically administered VEGF inhibitors as well as off-label use and medication error.

**EYLEA<sup>®</sup>**  
**(Aflibercept)**  
 EU Risk Management Plan

**Part II – Module SVII: Identified and Potential Risks**

**Table SVII.2: Overview of important potential risks**

<b>Important potential risk</b>	<b>Risk-benefit impact</b>
Arterial thromboembolic events (ATEs), including non-MI ATEs and cardiovascular ischemic events	<p>Intravenous injections of anti-VEGF agents at high doses used to treat cancer are known to be associated with an increased occurrence of arterial thromboembolic events (ATEs). Since Eylea is administered in very small doses directly into the eye, the risk of developing such systemic adverse events is considered very low. However, since Eylea belongs to the class of anti-VEGF therapies, arterial thromboembolic events are considered an important potential risk.</p> <p>The targeted analysis of adjudicated ATE according to the definitions provided by the Anti-Platelet Trialists' Collaboration (APTC) during the clinical development program is highly expressive, since the ATE terms are clearly defined and adjudicated by an independent data review committee. Consistently, the analyses in the AMD, CRVO, BRVO, myopic CNV, and DME studies did not show meaningful differences between Eylea and the respective parallel control groups. No dose-dependent trends could be observed in ATE incidences, and incidences were generally low. So far, there is no relevant indication that treatment with Eylea might be associated with an increased risk of arterial thromboembolic events. Systemic pharmacodynamic effects, including the development of ATEs, are deemed unlikely. ATE cases reported in post-marketing setting are subject to additional follow-up using specific questionnaires.</p>
Venous thromboembolic events	<p>Venous thromboembolic events have been associated with intravenous injection of anti-VEGF therapies at the doses used for cancer treatment. As with the remaining potential systemic class effect risks, the low incidence and the absence of dose dependency in the Phase III AMD, CRVO, BRVO, myopic CNV, and DME studies support that Eylea is unlikely to cause venous thromboembolic events.</p>
Hypertension	<p>Arterial hypertension has been associated with intravenous injection of anti-VEGF therapies at the doses used for cancer treatment. So far, there is no evidence that the very small doses of Eylea that are injected into the eye are associated with an increased risk of hypertension.</p> <p>Following IVT administration of aflibercept at the doses studied, free aflibercept is not present at sufficient plasma concentrations (or for a sufficient length of time) to induce meaningful reductions in available systemic active endogenous free VEGF. Importantly, aflibercept did not accumulate in plasma after IVT administration every 4 weeks (VIEW 2). A contributory role of Eylea to an increase in blood pressure is considered unlikely. Hypertension cases reported in post-marketing setting are subject to additional follow-up using specific</p>

**EYLEA<sup>®</sup>**  
(Aflibercept)  
EU Risk Management Plan

**Part II – Module SVII: Identified and Potential Risks**

**Table SVII.2: Overview of important potential risks**

Important potential risk	Risk-benefit impact
Proteinuria	questionnaires. Proteinuria is associated with intravenous injection of anti-VEGF therapies at the doses used for cancer treatment. The incidence of treatment-emergent proteinuria was low in patients treated with Eylea in the clinical development program and showed no dose dependency. There is no evidence that the very small doses of Eylea that are injected into the eye are associated with an increased risk of proteinuria.
Non-ocular hemorrhage	Non-ocular bleedings are associated with intravenous injection of anti-VEGF therapies at the doses used for cancer treatment. The similar event rates in the Eylea groups compared to the respective parallel groups (i.e., ranibizumab, sham, or laser) as well as the absence of any dose-response relationship among Eylea-treated patients in the Phase III AMD, CRVO, BRVO, myopic CNV, and DME studies suggest that Eylea is unlikely to cause non-ocular (systemic) hemorrhages.
Medication error	There is an excess volume in the marketed vial which exceeds the recommended net dose of 2 mg Eylea per injection. Thus, injection of more than the approved volume results in overdose. However, this numerical overdose is limited, and the drug will be administered only by qualified physicians (not by patients), and this reduces the risk of inappropriate dosing and administration as well. No clinically meaningful events of overdose have been reported so far (neither in clinical trials nor in usual care). Nevertheless, it was decided to consider "medication error " a potential risk of treatment, which is, however, completely avoidable by proper adherence to the dosing recommendations.
Off-label use and misuse	As with other drugs, Eylea might be intentionally used other than recommended, or in clinical conditions outside the approved indications. Eylea does not have any dependence potential. Since the clinical experience with Eylea in such off-label use is limited (in particular in terms of efficacy and safety), any case of off-label use is currently considered an important potential risk.  In addition, intentional off-label use in the context of multiple use of single use product (vial splitting) has been observed with Eylea. The Eylea vial is approved for single eye use only.
Embryo-fetotoxicity	As angiogenesis is a critical component of embryonic and fetal development, inhibition of angiogenesis following systemic administration of anti-VEGF therapies might result in adverse effects on pregnancy. The current experience with IVT-administered anti-VEGF therapies in pregnancy is sparse (single cases reported only) and thus inconclusive. However, early loss of pregnancy after IVT bevacizumab injection has been

**EYLEA<sup>®</sup>**  
**(Aflibercept)**  
 EU Risk Management Plan

**Part II – Module SVII: Identified and Potential Risks**

**Table SVII.2: Overview of important potential risks**

<b>Important potential risk</b>	<b>Risk-benefit impact</b>
	reported in a very few instances (163). Therefore, particular attention is paid to that safety issue. No cases of embryo-fetotoxicity were reported during the clinical development program; however, pregnant females were excluded from clinical study participation. Current post-marketing surveillance data do not suggest an increased risk of embryo-fetotoxicity on treatment with Eylea.
Retinal hemorrhage	Many ocular diseases, including wet AMD, CRVO, BRVO, or DME may lead to retinal bleeding. However, since rare cases of retinal hemorrhages were reported to be related to IVT treatment with anti-VEGF therapies, this condition is also considered an important potential risk.

Table SVII.3 provides an overview of the missing information for Eylea.

**EYLEA<sup>®</sup>**  
(Aflibercept)  
EU Risk Management Plan

**Part II – Module SVII: Identified and Potential Risks**

**Table SVII.3: Overview of missing information**

<b>Missing information</b>	<b>Risk-benefit impact</b>
Use of Eylea in patients with uncontrolled glaucoma	Eylea has not been studied in patients with uncontrolled glaucoma, and it is possible that the additional volume load and secondary transient increase in intraocular pressure caused by the IVT injection might be especially detrimental in those patients with uncontrolled glaucoma. The currently available data do not allow a final judgment of this theoretical concern. No additional PV activities are currently warranted.
Concomitant use of different anti-VEGF therapies and other therapies for wet AMD, CRVO, BRVO, myopic CNV, and DME (including bilateral anti-VEGF therapy).	Under real-world conditions patients may be simultaneously treated with numerous drugs, which might result in interferences that have never been evaluated in clinical studies. Thus, there is a certain probability that Eylea will be administered in combination (or in close temporal sequence) with other anti-VEGF therapies or other treatments for wet AMD, CRVO, BRVO, myopic CNV, and DME. The potential interferences and consequences of such combinations cannot be assessed at the moment; no additional PV activities are currently warranted.
Long term safety beyond 2 years	The clinical studies, which provided the basis for the approval of Eylea, did not cover a treatment period of longer than 2 years. However, since patients in the post-authorization phase are likely to be treated for longer than 2 years, it would be reasonable to systematically collect safety data beyond 2 years in order to assess the long-term safety of Eylea more appropriately. Sufficiently comprehensive data on the long-term safety of Eylea beyond the 2 years of administration is currently not available; no additional PV activities are currently warranted.
Posology utilized in marketed use	Dose recommendations are provided by the marketing authorization holder in the package insert and other documents. However, physicians might choose a different dosage, based on their expert medical opinion. It is useful for the marketing authorization holder to receive information about these intentional deviations from the recommended dosage in order to be better aware of how the medication is being used in practice. Currently, there is insufficient information about the posology actually being used by physicians in clinical practice. Two post-authorization efficacy studies (PAES) are currently being conducted in order to evaluate the effects of an “treat and extend” regimen vs. a fixed treatment regimen in patients with AMD and DME, respectively (Studies BAY 86-5321/16598 and BAY 86-5321/17613, respectively).

---

## **SVII.2 New Safety Concerns and Reclassification with a Submission of an Updated RMP**

No new safety concerns were identified since the last RMP update.

Based on the cumulative review of the proteinuria cases and the use of Eylea as displayed in PSUR#7, the PRAC Rapporteur concluded that “proteinuria” could be removed from the important potential risk list and the topic could be monitored through routine pharmacovigilance activities.

After a cumulative review of all cases received during the period covered by PSUR#9 (from 01 DEC 2018 to 30 NOV 2019) (Procedure no.: EMEA/H/C/PSUSA/00010020/201911), the PRAC Rapporteur recommended to include the AE “retinal haemorrhage” in the SmPC Section 4.8 under “Eye disorder” and delete it as important identified risk.

In Procedure No. EMEA/H/C/002392/II/0075 the PRAC recommended to shorten the list of safety concerns by removing some identified and potential risks not associated with additional risk minimisation measures such as retinal tear/detachment, hypersensitivity and immunology, arterial thromboembolic events, venous thromboembolic events, hypertension and non-ocular hemorrhage. These safety concerns will continue to be addressed in subsequent PSURs. Furthermore, PRAC requested to have the following Missing Information topics removed from the EU RMP due to lack of additional PV activities: Use of Eylea<sup>®</sup> in patients with uncontrolled glaucoma, Concomitant use of different anti-VEGF therapies and other therapies for wet AMD, CRVO and DME (including bilateral treatment with anti-VEGFs), Long term safety beyond 2 years.

Following completion of studies VIOLET and AZURE removal of Posology utilized in marketed use” as a missing information was requested in procedure No. EMEA-H-C-002392-II-0076.

## **SVII.3 Details of Important Identified Risks, Important Potential Risks, and Missing Information**

### **Overview of data sources (clinical studies and post-marketing data)**

#### **Overview of clinical studies**

Important identified and potential risks were determined considering the safety data of Eylea in the following studies:

- Pooled data of the pivotal Phase III AMD randomized controlled studies VIEW 1 and VIEW 2 (96 weeks),
- Open-label VIEW 1 extension study (VGFT-OD-0910),
- Phase III AMD randomized controlled study SIGHT (52 weeks),
- Phase IV AMD study ALTAIR (52 weeks),
- Pooled data of the Phase III CRVO randomized controlled studies GALILEO and COPERNICUS (76/100 weeks),
- Phase III BRVO randomized controlled study VIBRANT (52 weeks),
- Phase III myopic CNV randomized controlled study MYRROR (48 weeks),

**EYLEA<sup>®</sup>**  
(Aflibercept)  
EU Risk Management Plan

**Part II – Module SVII: Identified and Potential Risks**

---

- Pooled data of the pivotal Phase III DME randomized controlled studies VIVID-DME and VISTA-DME (148 weeks),
- Randomized, controlled Phase III DME study VIVID-EAST (52 weeks),
- Single-arm, open-label study Phase III DME study VIVID-JAPAN (52 weeks).

The presented figures represent crude incidences from the data, regardless of the investigator's causality attribution. The study designs are outlined in the following sections.

### Studies in wet AMD

For AMD, pooled data (**VIEW 1 [VGFT-OD-0605] and VIEW 2 [SN 91689] studies**) from baseline through 96 weeks<sup>7</sup> are primarily presented. In Year 1 of the studies, patients received fixed-dose treatment with ranibizumab 0.5 mg every 4 weeks (RQ4), VEGF Trap-Eye 0.5 mg every 4 weeks (0.5Q4), VEGF Trap-Eye 2 mg every 4 weeks (2Q4), and VEGF Trap-Eye 2 mg every 8 weeks (2Q8). The original dose of Year 1 (i.e., 0.5 or 2.0 mg per injection) was maintained in Year 2 of the studies, but the treatment intervals could be extended to 12 weeks at maximum according to pre-specified re-treatment criteria (modified quarterly dosing). The safety data of the 1,824 SAF patients treated in VIEW1 and VIEW 2 are presented by randomized treatment group at Baseline, i.e., RQ4 (N=595), VTE 0.5Q4 (N=601), VTE 2Q4 (N=613), and VTE 2Q8 (N=610).

VIEW 1 patients of any randomized treatment group who had completed the 96 weeks of the core study had the opportunity to start or continue treatment with Eylea 2 mg in the open-label, multi-dose VIEW 1 extension study (VGFT-OD-0910) conducted in order to assess the long-term safety and tolerability of Eylea. During the course of the study, patients were randomized in a 1:1:1 ratio to 3 treatment groups which differed in the packaging or sterilization techniques of Eylea 2 mg (i.e., vials, or one of the externally sterilized prefilled syringes [ethylene oxide, ETO, or hydrogen peroxide, VHP]) in order to investigate the safety profile of the different product configurations and external sterilization techniques. Eylea 2 mg was to be administered no more frequently than every 4 weeks and no less frequently than every 12 weeks (later on amended in the US to 8 weeks). A total of 323 VIEW 1 completers were enrolled in VGFT-OD-0910, 320 received study drug treatment in the extension phase with Eylea in the study eye (69 from the original RQ4 group, 87 from the original 0.5Q4 group, and 92 and 72 from the original 2Q4 and 2Q8 groups, respectively), and 281 were randomized to the different product specifications (93 to vials, 94 to ETO, and 94 to VHP). Three of the 323 subjects enrolled in the VIEW 1 extension study were last treated with Eylea 2 mg at Week 96 of the core VIEW 1 study (all 3 were randomized in the 2Q4 group) but did not receive treatment in the extension phase. These patients were nevertheless included in the safety set of the VIEW 1 extension study, as they had received Eylea at Week 96 of the VIEW 1 core study and thus were exposed to Eylea.

The mean treatment duration in VGFT-OD-0910 (excluding the core study period of 96 weeks) for all enrolled extension study patients (N=323) was 110.4 weeks. The safety data presented in this module are based on the safety events occurring during the extension period

---

<sup>7</sup> Patients in VIEW 2 who received their last study injection on Week 92 were to be followed up to Week 100 according to regulatory obligations. For the sake of straightforwardness, the duration of observation in both VIEW 1 and VIEW 2 is designated as 96 weeks (although some patients in VIEW 2 were observed for up to 100 weeks).

**EYLEA<sup>®</sup>**  
(Aflibercept)  
EU Risk Management Plan

**Part II – Module SVII: Identified and Potential Risks**

---

in the 323 patients (SAF) who were exposed to Eylea in the extension period (referred to as "Eylea total group"). Two additional analysis groups were defined, with

- i) patients who had been treated with ranibizumab in the preceding core study period (N=69; designated as "ranibizumab group" in the tables and "former ranibizumab group" in the running text), and
- ii) patients who had been treated with Eylea at any dose (i.e., 0.5 Q4, 2Q4, or 2Q8) already during the core study period (N=254; designated as "Eylea combined group" in the tables and "former Eylea groups" in the running text)).

This separation was deemed reasonable, because only the 254 patients from the original Eylea groups were on true long-term treatment with Eylea (i.e., beyond 96 weeks of treatment, for up to approximately 5 years in total). In the 320 subjects who also received treatment in the study extension period, a total of 7,215 injections were administered in the study eye from the original baseline in VIEW 1 through the end of the extension period (range: 12 to 61 injections), and the overall mean treatment duration was  $48.9 \pm 9.8$  months (range: 23 to 64 months).

**SIGHT (SN 13406)** was a randomized, double-masked, photodynamic therapy-controlled Phase III study in order to evaluate the efficacy, safety, and tolerability of Eylea in Chinese subjects with wet AMD. A total of 304 patients were randomized in a 3:1 ratio to treatment with Eylea 2 mg (N=228) or control treatment with PDT (N=76). Primary efficacy assessments were performed at Week 28. Patients in the Eylea 2 mg group received the first 3 IVT injections with Eylea every 4 weeks (i.e., at Baseline, Week 4 and Week 8) and subsequently every 8 weeks until Week 48 (i.e., at Weeks 16, 24, 32, 40, and 48). At Weeks 28 and 36, sham injections were additionally required. Patients in the PDT control group received one PDT procedure at baseline and were allowed to undergo additional PDT procedures through Week 28 as indicated according to local clinical practice and the clinical judgment of the investigator. Sham injections were administered in order to maintain the blind (while patients in the Eylea group underwent a sham PDT procedure at baseline and additional sham PDT procedures as indicated according to local clinical practice and the clinical judgment of the investigator). At Week 28, after all variables for the primary efficacy endpoint had been assessed and the data recorded, subjects in the PDT group were to receive one injection with Eylea 2 mg and subsequent injections with Eylea 2 mg at Weeks 32, 36, 40, and 48. Actually, 71 out of the 76 patients randomized to the PDT control group were exposed to Eylea. Safety data are presented for the entire study period through Week 52 by randomized treatment group (N=76 and 288, respectively) and additionally in the Eylea total group that includes all study patients who were exposed to Eylea (N=299; only AEs occurring during or after the first Eylea exposure are counted in the 71 original PDT patients who received Eylea from Week 28 onwards).

**ALTAIR (SN17668)** was a randomized, open-label phase 4 study evaluating the efficacy and safety of repeated doses of intravitreal aflibercept with variable treatment intervals in Japanese subjects with neovascular age-related macular degeneration. Eligible subjects received an IVT injection of aflibercept at every scheduled treatment visit. After completion of treatment at Week 16, the timing of the subsequent treatment visits was determined at the previous treatment visit by the treating physician based on the criteria of the Treat and Extend regimen. Subjects who had completed the run-in phase were randomly assigned to one of the

**EYLEA<sup>®</sup>**  
(Aflibercept)  
EU Risk Management Plan

**Part II – Module SVII: Identified and Potential Risks**

---

two treatment arms of the study (2-week [2W] adjustment group or 4-week [4W] adjustment group) in 1:1 ratio at Week 16. A total of 247 patients were randomized, 7 patients were treated but not randomized.

**2W adjustment group (N=124):** Aflibercept IVT injection at Week 0, Week 4, Week 8 and Week 16, followed by the variable treatment intervals based on the criteria of the Treat and Extend regimen.

If the study eye of a subject met the respective criteria for shortening or extension, length of either extension or shortening of the treatment interval was 2 weeks from the last interval, respectively.

**4W adjustment group (N=123):** Aflibercept IVT injection at Week 0, Week 4, Week 8 and Week 16, followed by the variable treatment intervals based on the criteria of the Treat and Extend regimen.

Shortening of interval: If the study eye of a subject met the criteria for shortening, the treatment interval was shortened by 2 weeks. However, if the last treatment interval of a subject had been extended by 4 weeks from the second last interval, the treatment interval was shortened by 4 weeks.

Extension: If the study eye of a subject met the criteria for extension, length of extension of the treatment interval was 4 weeks. However, when a subject had a history of receiving treatment with interval shortened by 4 weeks during this study, the length of the extension was 2 weeks.

Subjects were evaluated at Week 52 and Week 96, regardless of treatment schedule. In study eyes, only the study drug was administered while fellow eyes could receive any domestically approved treatments. If a subject was judged to need any extra treatment in the study eye either using study drug or non-study treatment, the subject terminated the study. Ophthalmic evaluations were done at every treatment and evaluation visits other than visit for safety follow-up using visual acuity test with ETDRS score, slit lamp and indirect ophthalmoscopy, and optical coherence tomography (OCT). Fundus photography (FP), FA and indocyanine green angiography (ICGA) were conducted at visit for screening, Week 52 and Week 96. In addition to these ophthalmic evaluations, general evaluation and vital sign assessment in subjects were used for safety evaluation methods. Aflibercept was administered every 4 weeks until Week 8 (Run-in phase). Subjects who completed the Run-in phase were randomly assigned to one of the two treatment arms of the study (2W adjustment group or 4W adjustment group) in 1:1 ratio at Week 16. After the IVT injection at Week 16, treatment was followed by a Treat and Extend regimen with variable treatment intervals up to Week 96 (Treatment phase). During Week 16 to Week 96, treatment interval between two injections must not be less than 8 weeks and must not be more than 16 weeks.

### **CRVO studies**

In the Phase III CRVO study **COPERNICUS (VGFT-OD-0819)**, patients received either Eylea or sham (2Q4) in the first 6 months (Week 24); in the second 6 months sham patients were able to receive active treatment depending on re-treatment criteria defined in the protocol. All subjects were allowed to continue PRN treatment through Year 2 (Week 100).

**EYLEA<sup>®</sup>**  
(Aflibercept)  
EU Risk Management Plan

**Part II – Module SVII: Identified and Potential Risks**

---

In the Phase III CRVO study **GALILEO (SN 14130)**, patients were treated either with Eylea or sham up to 52 weeks. During the 52 weeks study duration, sham patients were not foreseen to be treated with Eylea but could be treated with Eylea from Week 52 to Week 76.

The pooled safety data of the 2 CRVO studies are shown for the entire study period from Baseline to Week 76/100 (the study period was 76 weeks in GALILEO and 100 weeks in COPERNICUS). Treatment groups for data presentation are based on original randomization, i.e., 142 patients randomized to sham with subsequent PRN treatment and 218 patients randomized to Eylea 2Q4 with subsequent PRN treatment. In addition, AEs in all patients from either randomization group who received at least one active injection with Eylea are summarized from the day when the first injection was administered (N=317; i.e., excluding the 43 patients of the sham-PRN group who never received Eylea, referred to as "Eylea total group").

### **BRVO study**

**VIBRANT (VGFTe RVO-1027)** was a randomized, double-masked, active controlled 52-week study to evaluate the efficacy, safety, and tolerability of repeated IVT administration of Eylea compared with grid laser photocoagulation in subjects with macular edema secondary to BRVO. A total of 183 patients were randomized and exposed to study treatment (91 in the Eylea group and 92 in the laser group). The study was conducted by Regeneron Pharmaceuticals, Inc. in North America (USA, Canada) and Japan. Patients in the Eylea group received Eylea 2Q4 through (including) Week 24, then 2Q8 through Week 48. Sham IVT injections were administered every 8 weeks starting from Week 28, alternating with Eylea injections every 8 weeks, through Week 44. The last active injection with Eylea was on Week 48. Patients in the Eylea group also received one sham laser treatment on Day 1. Rescue treatment with active laser in this group was possible, if patients had met the pre-defined criteria at Week 36. Patients randomized to the laser group received grid laser photocoagulation treatment at Day 1, and sham IVT injections every 4 weeks from Day 1 through Week 48. Rescue treatment with laser was possible from Week 12 onwards (minimum intervals of 12 weeks from previous laser treatment) in those patients who had met the pre-specified criteria. Patients in the laser arm could become eligible for rescue treatment with Eylea beginning at Week 24. In this case, they were to receive 3 initial Eylea 2 mg injections every 4 weeks, followed by injections every 8 weeks. Safety data are presented in this RMP version for the final Week 52 study data as per randomized treatment group, i.e., based on the 91 patients in the VTE 2 mg group and the 92 patients in the Laser+VTE 2 mg group (i.e., patients randomized to initial treatment with laser through Week 20 and the option for Eylea rescue therapy beginning at Week 24). In addition, the Eylea total group (N=158) includes all patients who had received Eylea at least once (i.e., in addition to patients from the Eylea treatment group, the 67 patients in the Laser+VTE 2 mg group who had received rescue treatment with Eylea beginning at Week 24). In this group, all adverse events occurring after the first Eylea injection are counted.

### **Myopic CNV study**

In the multi-center, randomized, double-masked, sham-controlled, Phase III myopic CNV study **MYRROR (SN 5170)**, a total of 122 Asian subjects with active subfoveal or juxtafoveal CNV secondary to pathologic myopia were randomized to receive either Eylea 2.0 mg or sham injection. The primary efficacy endpoint (mean change in BCVA) was evaluated after 24 weeks of treatment (injections from baseline through Week 20). In this study period,

**EYLEA<sup>®</sup>**  
(Aflibercept)  
EU Risk Management Plan

**Part II – Module SVII: Identified and Potential Risks**

---

subjects in the Eylea group (N=91) received an active injection at Baseline and were then assessed at regular intervals of 4 weeks for the need of a repeated injection based on pre-defined re-treatment criteria (i.e., in case of recurring or persisting CNV). If no active injection was required, these subjects received a sham-injection. In the sham group (N=31), subjects underwent the same study-related procedures, but were solely treated with sham injections.

After the primary endpoint assessment at Week 24, all patients randomized to sham who continued the study (N=25) received one mandatory injection with active Eylea and continued treatment in the same way as in the Eylea 2 mg group, i.e., active injections, when pre-specified re-treatment criteria were met, or a sham injection otherwise. Patients were still monitored at monthly intervals; the last active injection could be given at Week 44, and the final study assessments were performed at Week 48.

This RMP version includes the final MYRROR study results through Week 48. Safety results of the MYRROR are presented for treatment groups as randomized (i.e., Sham+Eylea 2 mg group [N=31] vs. Eylea 2 mg group [N=91]) and additionally for all patients who were treated with active Eylea at least once during the study period (Eylea total group [N=116]).

### **DME studies**

**VIVID-DME (SN 91745)** and **VISTA-DME (VGFT-OD-1009)** were both 3 year, randomized, double-masked, active-controlled, multi-center, Phase III studies of the efficacy and safety of repeated doses of Eylea in subjects with DME with central involvement. In VIVID-DME, a total of 404 subjects (SAF) were treated in European countries, Australia, and Japan. In VISTA-DME, a total of 461 subjects (SAF) were treated in the US.<sup>8</sup> The studies had nearly identical overall study designs and are described together unless otherwise indicated.

Patients were randomized to 1 of the following 3 treatment groups: Eylea 2Q4 to Week 148, Eylea 2Q8 8 (after 5 initial monthly doses), with sham injections at alternating visits, to Week 148, or laser photocoagulation through Week 148 plus sham injection. Subjects in the Eylea groups received sham laser at Baseline and at visits, at which subjects met the criteria for laser re-treatment (no more often than every 12 weeks). The last administration of study treatment in all treatment groups was at Week 144.

Subjects in all groups were assessed for additional treatment (i.e., "rescue" treatment with Eylea for the laser subjects, and laser for the Eylea subjects) for inadequate responders at each visit starting at Week 24. Additional treatment was to be administered if pre-specified criteria were met.

During Year 3, subjects randomized to the laser group who did not meet the criteria for additional treatment previously were allowed to receive Eylea as needed (PRN) according to the Eylea re-treatment criteria from Week 100 through the end of the study (Week 144).

---

<sup>8</sup> As per amendment No. 4, patients completing Visit 39 (Week 148) in VISTA-DME were allowed to receive further treatment extension with Eylea until the planned date for the last on-study patient to complete Visit 39 (November 2014) in order to avoid a potential treatment gap between study end and availability of commercial Eylea. However, the exposure and safety analyses in VISTA-DME are aligned with VIVID-DME and thus limited to the last core study visit (i.e., Week 148).

**EYLEA<sup>®</sup>**  
(Aflibercept)  
EU Risk Management Plan

**Part II – Module SVII: Identified and Potential Risks**

---

Fellow eye treatment for DME with anti-VEGF agents was allowed in both studies. In VIVID-DME, standard of care was used (including ranibizumab or bevacizumab; licensed treatment preferred). In VISTA-DME, VEGF Trap-Eye was provided and required as fellow eye treatment (although ranibizumab could be used, if VEGF Trap-Eye was unavailable due to logistical reasons).

The primary efficacy endpoint in both studies was the change in ETDRS letter score from Baseline to Week 52. In this RMP version, the final safety-related results through Week 148 are reported. The pooled DME safety results from VIVID-DME and VISTA-DME are presented with tabulated summaries using the following patient groups:

- Laser group (active control): All patients in the SAF randomized to initial treatment with laser. All treatment-emergent AEs up to study end (Week 148) are considered for the analysis.
- VTE 2Q4 group: All patients in the SAF randomized to initial treatment with 2 mg VEGF Trap-Eye every 4 weeks. All treatment-emergent AEs up to study end (Week 148) are considered for the analysis.
- VTE 2Q8 group: All patients in the SAF randomized to initial treatment with 2 mg VEGF Trap-Eye every 4 weeks until Week 16 (i.e., a total of 5 initial monthly doses) and subsequent dosing intervals of 8 weeks (2Q8). All treatment-emergent AEs up to study end (Week 148) are considered for the analysis.
- VTE total (Eylea total group): All subjects (including patients randomized to the laser group) who have received at least one active Eylea injection in the study eye by Week 144. Considered are all treatment-emergent events that started after first study eye exposure to Eylea up to Week 148.

For the interpretation of the DME safety results based on these groups, it should be considered that:

- Patients in all randomized treatment groups were allowed to receive fellow eye treatment with Eylea or other anti-VEGF therapies (this should be particularly considered for the assessment of potential systemic adverse events),
- Patients in the laser group were allowed to receive additional treatment of the study eye with Eylea from Week 24 onwards or Eylea PRN (if re-treatment criteria were met and no additional treatment with Eylea was previously started) in the third year of the study (actually, 243 subjects in the laser group have received at least one additional or PRN treatment with Eylea by Week 144),
- Patients in either Eylea group were allowed to receive additional treatment of the study eye with active laser from Week 24 onwards (actually, 17 subjects in the 2Q4 group and 32 subjects in the 2Q8 group have received at least one additional treatment with active laser by Week 144), and
- The group of subjects included in the VTE total group consisted of the 578 subjects who were enrolled in the Eylea groups plus the 243 subjects the laser group who had received additional (rescue) treatment with VTE in the study eye for varying amounts of time, depending upon when they met the criteria for additional treatment or PRN treatment with VTE (possible in Year 3). In these patients, TEAEs occurring at or after the first exposure to Eylea are considered.

**EYLEA<sup>®</sup>**  
(Aflibercept)  
EU Risk Management Plan

**Part II – Module SVII: Identified and Potential Risks**

---

The study design of **VIVID-EAST (SN 15161)** was very similar to the designs of the pivotal studies VIVID-DME and VISTA-DME in the first year, and was conducted in China, Hong Kong, Republic of Korea, and the Russian Federation. The primary efficacy variable was the change from baseline in BCVA in ETDRS letter score at week 52. A total of 378 SAF patients were randomized to treatment with laser photocoagulation (N=124), the Eylea 2Q4 (N=127), or Eylea 2Q8 (N=127). Laser patients were treated with laser photocoagulation at baseline and from week 12 onwards, if laser-re-treatment criteria were met. Patients in the Eylea 2Q4 group received Eylea 2 mg at monthly intervals continuously through Week 48, and patients in the Eylea 2Q8 group received Eylea 2 mg every 2 months following 5 initial injections at monthly intervals (i.e., from Baseline to including Week 16) through Week 48. As with the pivotal studies, additional treatment with Eylea in the laser group (or with laser in the Eylea groups) was permitted from Week 24 onwards in the case that pre-defined additional treatment criteria were met. The last study treatment was administered on Week 48; final study assessments were performed at Week 52. The safety data are presented by randomized treatment group, and in the Eylea total group considering all TEAEs that occurred at or after the first administration of Eylea (N=299; i.e., the 254 patients initially randomized to Eylea treatment plus 45 laser group patients who received Eylea as additional treatment during the course of the study at Week 24 at the earliest). Generally, the aforementioned considerations about the interpretation of the safety data in the pivotal DME studies do also apply to VIVID-EAST.

**VIVID-JAPAN (SN 15657)** was a 1-year, open-label Phase III study performed in Japan with a treatment schedule that was generally similar to the 2Q8 arm in the randomized, controlled studies, i.e., all subjects were treated (in an open-label fashion) with Eylea 2 mg every 2 months (2Q8) after 5 initial doses at monthly intervals (i.e., 2Q4 up to Week 16). Last treatment was on Week 48; the final endpoint assessments were performed at Week 52. No additional treatment of the study eye with laser was permitted. Fellow eye treatment was allowed as per local standard of care/medical routine. Study assessments included effectiveness and safety of treatment as well as PK analyses. The safety analyses were performed without further stratification in a total of 72 subjects (one of the 73 enrolled and treated patient was excluded from the SAF because he/she withdrew consent).

### **Post-marketing data**

In addition to the clinical study data, the post-marketing cases for the important identified and potential risks, cumulating from market launch through cut-off date 15 SEP 2017, are provided (MedDRA version 20.0). These cases include spontaneously reported cases and cases from non-interventional studies (incl. solicited sources such patient support programs and market research programs), both medically confirmed and non-confirmed cases, and both valid and invalid cases (i.e., one case might include more than one patient).

Invalid/incomplete cases in Bayer's Global Pharmacovigilance Safety Database are defined as cases where at least one of the 4 minimal criteria is not fulfilled. These 4 minimal criteria are: i) identifiable patient, ii) identifiable reporter, iii) suspect Bayer product (in development or marketed drug/device), and iv) an adverse event. Adverse events can include reports of lack of drug effect, medication error, overdose, drug abuse, drug misuse, drug dependency, occupational exposure, pre-existing condition improved, off-label use, drug exposure via mother/father without adverse event and incident reports for medical devices. Reports which fulfil at least the two criteria "adverse event" and "suspect BHC medical product" according

**EYLEA<sup>®</sup>**  
(Aflibercept)  
EU Risk Management Plan

**Part II – Module SVII: Identified and Potential Risks**

---

to the above definitions are recorded and fully processed in the MAH's database. These cases are marked as invalid cases in the Global Pharmacovigilance Safety Database.

### **Evidence sources and strength of evidence**

The evidence sources for the evaluation of identified and potential risks are

- Clinical trial data:
  - AMD: 96 weeks dataset of the two Phase III studies VIEW 1 and VIEW 2,
  - AMD: Final dataset of the VIEW 1 extension study VGFT-OD-0910,
  - AMD: 52 weeks data set of the SIGHT study,
  - AMD: 52 weeks data set of the ALTAIR study,
  - CRVO: 76/100 weeks datasets of the two Phase III studies COPERNICUS and GALILEO,
  - BRVO: 52 weeks dataset of the Phase III study VIBRANT,
  - Myopic CNV: 48 weeks dataset of the Phase III study MYRROR,
  - DME: 148 weeks datasets of the two Phase III studies VIVID-DME and VISTA-DME,
  - DME: 52 weeks dataset of the VIVID-EAST study,
  - DME: 52 weeks dataset of the VIVID-JAPAN study.
- Post-marketing data (pharmacovigilance database; cut-off date 15 SEP 2017).
- Background incidence/prevalence: see embedded references.

Thus, the evidence is primarily based on randomized controlled clinical trials, which are considered highly evident sources. Complementary information is provided by post-marketing surveillance.

### **SVII.3.1 Presentation of Important Identified Risks and Important Potential Risks**

#### **SVII.3.1.1 Identified risk: Endophthalmitis (likely infectious origin)**

##### **Potential mechanisms**

The intravitreal injection procedure can implant pathogens into the eye if there is a break in sterile technique. Source of pathogenic agents is in most cases the patient's conjunctival bacterial flora.

##### **Evidence source(s) and strength of evidence**

###### Main reason for considering endophthalmitis as an important identified risk

Inflammation of the inner structures of the eye (in particular the vitreous body, which fills the globe) may occur as a result of an infection with microorganisms, either through direct traumatic injury of the eye (exogenous infection) or through spreading of microorganisms from other areas of the body (endogenous infection). This pathogen-caused inner eye (intraocular) infection is called endophthalmitis. In cases of inflammation where no pathogens can be identified (no/negative culture growth of microorganisms observed), the condition may be characterized as "sterile endophthalmitis" or "non-infectious endophthalmitis".

**EYLEA<sup>®</sup>**  
(Aflibercept)  
EU Risk Management Plan

**Part II – Module SVII: Identified and Potential Risks**

Because of the risk of severe vision loss, treatment should be initiated as soon as possible, and, depending on cause and severity, may consist of topical and intravitreal application of antibiotics, corticosteroids, and surgical removal of matter and infected structures (drainage, vitrectomy). The proportion of Eylea-exposed patients who experienced endophthalmitis in the study eye in the clinical studies with Eylea ranged from 0% to 0.9% (VIEW 1 extension study).

Evidence sources: refer to the [linked subsection](#).

MedDRA search terms (version 19.1 for clinical studies and version 20.0 for PM data):

Preferred terms included in search: Candida endophthalmitis, endophthalmitis, eye infection, eye infection bacterial, eye infection chlamydial, eye infection fungal, eye infection intraocular, eye infection staphylococcal, infectious iridocyclitis, infective iritis, infective uveitis, mycotic endophthalmitis, and necrotising retinitis.

### Characterization of the risk

#### Frequency

AMD - Pivotal Clinical Trials VIEW 1 and VIEW 2 (pooled data, 96 weeks)

The overall 96-week incidence of endophthalmitis (likely infectious origin, hereinafter referred to simply as endophthalmitis) was 0.3% and 1.0% in the combined Eylea and in the ranibizumab group, respectively (see [Table SVII.4](#) below).

**Table SVII.4: Number of subjects with endophthalmitis in the study eye (grouped term and included preferred terms) in randomized Phase III wet AMD studies from baseline through Week 96 (Pool 1, SAF)**

MedDRA 19.1	Ranibizumab		Eylea		Total n (%)
	Q4 n (%)	2 mg Q4 n (%)	0.5 mg Q4 n (%)	2 mg Q8 n (%)	
Number of subjects	595	613	601	610	1824
Grouped term					
Endophthalmitis	6 (1.0)	4 (0.7)	1 (0.2)	0	5 (0.3)
Included preferred terms					
Endophthalmitis	5 (0.8)	4 (0.7)	1 (0.2)	0	5 (0.3)
Eye infection	1 (0.2)	0	0	0	0

Q4 = every 4 weeks, Q8 = every 8 weeks

Note: All reported events were considered serious (see Table 1.3/4a); the Eylea-treated patients were completely recovered by the end of the study, 4 patients in the ranibizumab group were completely recovered and one was recovered with sequelae (Table 1.3/3a).

Table Source: Integrated Analysis - EU-RMP Pool 1 (AMD), Table 1.1.1/1

The incidence of endophthalmitis in the Eylea treatment arms was very low (0.3%), which is below the incidence reported in the literature for IVT administration of VEGF inhibitors (1.0% to 1.1%; see background incidence/prevalence information).

AMD - VIEW 1 long-term extension study

Three patients (one in the former randomized ranibizumab group [1.4%] and 2 in the former randomized Eylea groups [0.8%] experienced endophthalmitis in the study eye during the extension study period ([Table SVII.5](#)). There were no meaningful differences compared with

**EYLEA<sup>®</sup>**  
(Aflibercept)  
EU Risk Management Plan

<sup>a</sup>: All subjects randomized to initial study eye treatment with active laser.

<sup>b</sup>: All subjects randomized to initial study eye treatment with Eylea (VTE 2Q4 or 2Q8).

<sup>c</sup>: All subjects from any treatment group (incl. laser group; N=243 exposed to additional/PRN treatment with Eylea) who received at least one active Eylea injection in the study eye; counting all AEs which started during or after the first Eylea injection in the study eye through Week 148.

Table Source: Integrated Analysis - EU-RMP Pool 1 (DME), Table 1.5.1/1

DME - Clinical Trial VIVID-EAST (52 weeks)

No events pertaining to the group of endophthalmitis in the study eye were reported in the VIVID-EAST study.

DME - Open-label Clinical Trial VIVID-JAPAN (52 weeks)

No cases of endophthalmitis in the study eye were reported in the VIVID-JAPAN study.

Post-Marketing Data

A total of 844 cases (including 880 events) belonging to the endophthalmitis group were reported by cut-off date 15 SEP 2017 (see [Table SVII.8](#)).

An individual case review of the endophthalmitis cases was performed in order to check whether the diagnosis of endophthalmitis was substantiated by direct evidence of pathogens detected through e.g., tap culture. This review showed that in 232 of the 844 endophthalmitis cases (i.e., 27.5% based on all 844 cases or 66.9% based on the 347 cases with a documented test result) pathogens were identified. In the remaining cases, the samples were negative (115 cases), tests were performed but no outcomes provided (57 cases), or tests not reported/not performed (440 cases).

Considering the sales figures and the estimated cumulative patient exposure in the post-marketing period until 30 SEP 2017, the reporting rate of endophthalmitis cases (N=844) was

**EYLEA<sup>®</sup>**  
(Aflibercept)  
EU Risk Management Plan

**Part II – Module SVII: Identified and Potential Risks**

0.05 cases per 1,000 sold vials (0.005%) and 0.36 cases per 1,000 patient years (0.036%), respectively. The incidence reported thus far during post-authorization use is within the reported incidence reported in the literature with the IVT injection of anti-VEGF agents and other drugs (see sections on incidence and prevalence).

### Seriousness/outcomes

#### AMD - Pivotal Clinical Trials VIEW 1 and VIEW 2 (pooled data, 96 weeks)

All PT "endophthalmitis" events reported in the 5 patients treated with ranibizumab and in the 5 patients treated with Eylea were considered serious, while the single event "eye infection" in the ranibizumab group was non-serious.

All events of endophthalmitis in the Eylea-treated patients were completely resolved by the end of the study. In the ranibizumab group, 5 cases were resolved and one case (PT: "Endophthalmitis") was resolved with sequelae.

#### AMD - VIEW 1 long-term extension study

All 3 reported endophthalmitis cases were considered serious. Two cases were resolved, in the remaining case (one patient [0.4%] in the former randomized Eylea groups; N=254) the outcome was "recovered/resolved with sequelae".

#### AMD - Clinical Trial SIGHT (52 weeks)

No events pertaining to the group of endophthalmitis in the study eye were reported during the course of the SIGHT study.

#### AMD - Clinical Trial ALTAIR (52 weeks)

No events pertaining to the group of endophthalmitis in the study eye were reported during the course of the ALTAIR study.

#### CRVO Clinical Trials COPERNICUS and GALILEO (pooled data, 76/100 weeks)

The only reported event of endophthalmitis (in the Eylea 2Q4+PRN group) was considered serious and the patient completely recovered by the end of the study.

**EYLEA<sup>®</sup>**  
(Aflibercept)  
EU Risk Management Plan

**Part II – Module SVII: Identified and Potential Risks**

BRVO Clinical Trial VIBRANT (52 weeks)

No cases of endophthalmitis in the study eye were reported through Week 52 in the BRVO study VIBRANT.

Myopic CNV Clinical Trial MYRROR (48 weeks)

No endophthalmitis cases were reported in the MYRROR study through Week 48.

DME - Pivotal Clinical Trials VIVID-DME and VISTA-DME (pooled data, 148 weeks)

All 3 endophthalmitis events (occurring in 3 patients through Week 148) were regarded as serious; all 3 patients recovered (see [Table SVII.9](#)).

**Table SVII.9: Number of subjects with endophthalmitis in the study eye by outcome in the pivotal Phase III DME studies from baseline through Week 148 (SAF)**

MedDRA 19.1	Laser <sup>a</sup> n (%)	VTE 2Q4 <sup>b</sup> n (%)	VTE 2Q8 <sup>b</sup> n (%)	VTE total <sup>c</sup> n (%)

<sup>a</sup>: All subjects randomized to initial study eye treatment with active laser.

<sup>b</sup>: All subjects randomized to initial study eye treatment with Eylea (VTE 2Q4 or 2Q8).

<sup>c</sup>: All subjects from any treatment group (incl. laser group; N=243 exposed to additional/PRN treatment with Eylea) who received at least one active Eylea injection in the study eye; counting all AEs which started during or after the first Eylea injection in the study eye through Week 148.

Table Source: Integrated Analysis - EU-RMP Pool 1 (DME), Table 1.5.1/3

DME - Clinical Trial VIVID-EAST (52 weeks)

No events pertaining to the group of endophthalmitis in the study eye were reported in VIVID-EAST.

DME - Open-label Clinical Trial VIVID-JAPAN (52 weeks)

No cases of endophthalmitis in the study eye were reported in the VIVID-JAPAN study.

Post-marketing Data

Almost all of the 844 reported endophthalmitis events were serious (850 events; see previous post-marketing table on endophthalmitis).

Reported outcomes were "recovered/resolved" in 206 events, "recovering/resolving" in 99 events, "recovered/resolved with sequelae" in 28 events, and "not recovered/not resolved" in 105 events (missing or unknown outcomes in the remaining 442 events).

**Severity and nature of risk**

AMD - Pivotal Clinical Trials VIEW 1 and VIEW 2 (pooled data, 96 weeks)

Four out of the 5 endophthalmitis cases were classified as severe in the combined Eylea group (see [Table SVII.10](#) below), and 4 out of 6 cases were severe in the ranibizumab group.

**EYLEA<sup>®</sup>**  
(Aflibercept)  
EU Risk Management Plan

**Part II – Module SVII: Identified and Potential Risks**

Out of 5 cases with reported endophthalmitis in Eylea-treated patients, 3 were identified as culture-positive endophthalmitis.

**Table SVII.10: Number of subjects with grouped term endophthalmitis by maximum severity in randomized Phase III wet AMD studies from baseline through Week 96 (Pool 1, SAF)**

MedDRA 19.1	Ranibizumab		Eylea		Total n (%)
	Q4 n (%)	2 mg Q4 n (%)	0.5 mg Q4 n (%)	2 mg Q8 n (%)

Mild	1 (0.2)	0	0	0	0
Moderate	1 (0.2)	0	1 (0.2)	0	1 (<0.1)
Severe	4 (0.7)	4 (0.7)	0	0	4 (0.2)

Q4 = every 4 weeks, Q8 = every 8 weeks

Note: At each level of subject summarization (Safety topic/PT), a subject is classified according to the maximum intensity, if the subject reported one or more events. At each level of subject summarization, a subject is counted only once.

Table Source: Integrated Analysis - EU-RMP Pool 1 (AMD), Table 1.1.1/2

AMD - VIEW 1 long-term extension study

The severity of the 3 reported endophthalmitis cases (all were serious) was moderate in 2 cases and severe in the remaining case (one patient [0.4%] in the former Eylea groups; N=254).

AMD - Clinical Trial SIGHT (52 weeks)

No events pertaining to the group of endophthalmitis in the study eye were reported during the course of the SIGHT study.

CRVO Clinical Trials COPERNICUS and GALILEO (pooled data, 76/100 weeks)

Endophthalmitis was reported in one subject in the Eylea group and was classified as of "severe" nature. The vitreous culture was positive for coagulase-negative Staphylococcus.

AMD - Clinical Trial ALTAIR (52 weeks)

No events pertaining to the group of endophthalmitis in the study eye were reported during the course of the ALTAIR study.

BRVO Clinical Trial VIBRANT (52 weeks)

No cases of endophthalmitis in the study eye were reported through Week 52 in the BRVO study VIBRANT.

Myopic CNV Clinical Trial MYRROR (48 weeks)

No endophthalmitis cases were reported in the MYRROR study through Week 48.

DME - Pivotal Clinical Trials VIVID-DME and VISTA-DME (pooled data, 148 weeks)

Two of the 3 reported endophthalmitis events were severe and one event was moderate (see [Table SVII.11](#)).

Table Source: Integrated Analysis - EU-RMP Pool 1 (DME), Table 1.5.1/2

#### DME - Clinical Trial VIVID-EAST (52 weeks)

No events pertaining to the group of endophthalmitis in the study eye were reported in VIVID-EAST.

#### DME - Open-label Clinical Trial VIVID-JAPAN (52 weeks)

No cases of endophthalmitis in the study eye were reported in the VIVID-JAPAN study.

#### Post-marketing Data

Event severity is not routinely recorded on the post-marketing case report forms.

### **Background incidence/prevalence**

#### Incidence of endophthalmitis after IVT anti-VEGF injections

A systematic review of 278 publications was published in 2011 to identify adverse events associated with anti-VEGF injections. Endophthalmitis was reported with incidence rates below or equal to 0.04 (95% CI: 0.02–0.08), 0.05 (95% CI: 0.03–0.10) per 100 injections for ranibizumab and bevacizumab<sup>9</sup>, respectively (164)(164)(164)(164)(164)(164)(164).

#### Reports from wet AMD studies

The Phase III trials for ranibizumab (Lucentis<sup>®</sup>) – ranibizumab for wet AMD (MARINA) and ranibizumab versus verteporfin for wet AMD (ANCHOR) – demonstrated a low rate of endophthalmitis. At 96 sites in the US, of the 716 patients enrolled in the 2-year MARINA study, 478 patients received 0.3 mg or 0.5 mg ranibizumab and 238 patients received sham injection. The endophthalmitis rate was 1.0% (5 of 477 patients), or, alternatively, a rate per injection of 0.05% (5 of 10,443 total injections) (165). Similar incidence rates of 1.1% (3 of 277 patients or of 0.05% per injection (3 of 5,921) were reported in the ANCHOR study where 5,921 injections of ranibizumab were administered. In this study 423 patients were

<sup>9</sup> Please note that bevacizumab is not approved for treatment of ocular disorders and no formal PV system has been established in ophthalmological use. Thus, published data on bevacizumab might be limited.

**EYLEA<sup>®</sup>**  
(Aflibercept)  
EU Risk Management Plan

**Part II – Module SVII: Identified and Potential Risks**

---

randomized 1:1:1 in 83 international sites to verteporfin photodynamic therapy (PDT) plus monthly sham intraocular injection (n=143) or to sham verteporfin PDT plus monthly IVT ranibizumab (0.3 mg or 0.5 mg) injection (140 each in the 2 ranibizumab groups) (28). A review of safety data performed by Mitchell et al. reported that 3,252 patients in ANCHOR, MARINA, PIER, and SAILOR study received over 28,500 IVT ranibizumab injections. The overall rate of endophthalmitis in these studies was 0.05% per injection (41).

In the United Kingdom (UK) a 12-month prospective, double masked, multicenter, randomized controlled trial (ABC Trial) enrolled 131 patients (mean age 81) from 3 centers with wet AMD to receive IVT bevacizumab (1.25 mg, 3 loading injections at 6-week intervals followed by further treatment if required at 6-week intervals, n=65) or the standard treatment available at the start of the trial (PDT with verteporfin for predominantly classic type wet AMD, n=16, or IVT pegaptanib, n=38, or sham treatment, n=12, for occult or minimally classic type AMD). There were no cases of endophthalmitis (166).

In 2 Phase III multicenter trials (VISION I and II trial), which evaluated 2 years of therapy with pegaptanib sodium injection for wet AMD, a total of 7,545 IVT pegaptanib sodium injections and 2,557 sham injections were administered. A total of 1,190 patients were randomized to receive 0.3 mg, 1 mg, or 3 mg of pegaptanib sodium by intravitreal injection or sham injection every 6 weeks. The reported endophthalmitis incidence per injection was 0.16%. Most of the cases (75%) resulted from violations of the injection preparation protocol and the rate dropped to 0.07% in the 2nd year after reinforced aseptic procedure (167). During the 3rd year of the VISION trials 422 patients received 3,227 pegaptanib injections and the endophthalmitis rate per injection was 0.06% (168).

No cases of endophthalmitis or intraocular inflammation were reported in the randomized controlled wet AMD-PCV studies LAPTOP over 12 months (169) or EVEREST study over 6 months (170).

#### Reports from CRVO studies

A Phase III, prospective, randomized, sham controlled, double masked, multicenter clinical trial of ranibizumab injection in patients with macular edema secondary to CRVO (CRUISE Study) enrolled 392 patients to monthly IVT injections of 0.3 mg or 0.5 mg of ranibizumab (n=262) or sham (n=130) injections. The 6-month primary end point results reported no events of endophthalmitis (171), as did the 12-month primary end point results (172). The total number of injections was not published.

A dose-ranging, double-masked, multicenter, sham controlled, Phase II trial included 98 subjects with CRVO of ≤6 months duration and assigned them (1:1:1) to receive pegaptanib sodium (0.3 mg and 1 mg, n=33 each) or sham (n=32) injections every 6 weeks for 24 weeks. This study was conducted in practitioners' offices and clinics in Australia, France, Germany, Israel, Spain, and the US. No subject developed endophthalmitis (173). The total number of injections has not been published.

#### Reports from BRVO studies

The Pan American Collaborative Retina Study Group conducted an interventional, retrospective, comparative multicenter study with 63 patients (63 eyes) with macular edema secondary to BRVO that were treated primarily with IVT bevacizumab. Patients were recruited at 8 institutions in Costa Rica, Venezuela, Puerto Rico, Brazil, Peru, Mexico,

**EYLEA®**  
(Aflibercept)  
EU Risk Management Plan

**Part II – Module SVII: Identified and Potential Risks**

---

Argentina, and Spain and had at least 24 months of follow-up. During the 24 months, there were 138 injections recorded in the 1.25 mg dose group and 109 injections in the 2.5 mg dose group. There were no cases of endophthalmitis (174).

In a randomized controlled trial (175) of intravitreal 0.5-ranibizumab injection versus standard grid laser for macular edema following BRVO, there were no events of endophthalmitis, during the 12-month-long treatment period. A total of 36 patients with vision loss in one eye attributable to macular edema were included in the study.

In a randomized controlled clinical trial (BRAVO) to assess 12-month efficacy and safety of intraocular injections of 0.3 mg (n=134) or 0.5 mg ranibizumab (n=131) vs. sham treatment (n=132) in patients with macular edema secondary to BRVO (n=397) (126), one case of endophthalmitis was reported in the ranibizumab 0.5 mg treatment group (n=131, incidence 0.8%). The follow-up study (HORIZON) on ranibizumab for macular edema due to RVO reported no cases of endophthalmitis (in BRVO or CRVO) during the 12 months follow-up period (176).

The SCORE-BRVO study compared the efficacy and safety of 1 mg and 4 mg doses of intravitreal triamcinolone with standard of care (grid photocoagulation in eyes without dense macular hemorrhage and deferral of photocoagulation until hemorrhage cleared in eyes with dense macular hemorrhage) for eyes with vision loss associated with macular edema secondary to BRVO. A total of 411 participants were randomized and followed for 12 months. Through month 12, there were neither reports of infectious endophthalmitis in the standard of care group (n=137) nor in the 1 mg triamcinolone group (n=136), but one case (incidence =0.7%) was reported in the 4 mg triamcinolone group (n=138) 3 days after the third injection (122).

In Russo et al. 2009 (bevacizumab compared with macular laser grid photocoagulation in a randomized, controlled study, in 30 consecutive eyes with macular edema in BRVO), no cases of endophthalmitis were reported (177).

Parodi et al. (178), compared the effectiveness of sub-threshold grid laser treatment (SGLT) with infrared micropulse diode laser alone (n=13) or in combination with intravitreal triamcinolone injection (n=11) in BRVO patients. No endophthalmitis events were observed during the 12 months follow-up study period.

In Donati et al. (179) evaluating in an open-label study the long-term efficacy of intravitreal bevacizumab (IVB) versus combined IVB and macular grid laser photocoagulation for the treatment of macular edema secondary to BRVO, no sterile or infectious endophthalmitis events were observed.

#### Reports from myopic CNV studies

In a case series, records of 35 consecutive patients who were treated with intravitreal injection of bevacizumab from 18 DEC 2008, through 20 JAN 2009 were reviewed. Of the 35 patients, five developed severe intraocular inflammation. There were three patients with myopic CNV, of whom one developed the condition. It was a 49-year-old woman who received one intravitreal bevacizumab injection and symptoms were identified four days after the injection. All five cases were culture negative (180).

In a Japanese study, bevacizumab was aliquotted into smaller doses (5 mg/0.2 ml x 20). Intravitreal bevacizumab (1.25 mg/0.05 ml) was injected into nineteen eyes of fifteen patients,

**EYLEA<sup>®</sup>**  
(Aflibercept)  
EU Risk Management Plan

**Part II – Module SVII: Identified and Potential Risks**

---

two of whom (three eyes) had myopic CNV. Ocular inflammation occurred in 14 eyes of 11 patients, including both of the myopic CNV patients (male age 61, female age 82 in both eyes). Both myopic CNV patients required pars plana vitrectomy (181).

No cases of endophthalmitis were reported through Month 12 in the myopic CNV study RADIANCE (182).

Reports from DME studies

A 12-month, randomized, sham controlled, double-masked, multicenter Phase II study of safety and efficacy of ranibizumab in DME with center involvement (RESOLVE Study) enrolled 151 subjects to either ranibizumab (0.3 mg, n=51; or 0.5 mg, n =51) or sham treatment (n=49). Two cases of endophthalmitis were reported in the ranibizumab treatment group (2%) and no cases in the sham group (129). The total number of injections was not published.

Two 24 month, parallel, methodologically identical, randomized, multicenter, double-masked, sham injection-controlled, Phase III studies (RISE and RIDE) to evaluate efficacy and safety of intravitreal ranibizumab in DME. In RISE, 377 patients were randomized to either ranibizumab (n=125 to 0.3mg and n=125 to 0.5mg) or sham injection (n=127) out of which one case of endophthalmitis occurred in the 0.3mg ranibizumab treatment group (0.8%) and no case of endophthalmitis in 0.5mg ranibizumab and sham group. Total number of injections in sham group was 2,461, 0.3mg ranibizumab was 2,682 and 0.5mg ranibizumab was 2628 in RISE study. In RIDE, 382 patients were randomized to either ranibizumab (n=125 to 0.3mg and n=127 to 0.5mg) or sham injection (n=130) out of which one case of endophthalmitis occurred in the 0.3mg ranibizumab treatment group (0.8%), two cases of endophthalmitis in 0.5mg ranibizumab treatment group (1.6%) and no cases in sham group. Total number of injections in the sham group was 2,647, 0.3mg ranibizumab was 2,560 and 0.5mg ranibizumab was 2,714 in the RIDE study (128).

A 12-month, randomized, laser controlled, double masked, multicenter Phase III study to demonstrate superiority of ranibizumab 0.5 mg monotherapy or combined with laser over laser alone in DME patients (RESTORE study). 345 patients were randomized to ranibizumab + sham laser (n = 116), ranibizumab + laser (n = 118), or sham injections + laser (n = 111). No cases of endophthalmitis were reported in any treatment arms. Total number of injections in ranibizumab + sham laser was 800, ranibizumab + laser was 816 and sham injections + laser were 802 (183).

A 6-month phase 2 randomized, multi-center clinical trial of intravitreal bevacizumab for DME conducted by the Diabetic Retinopathy Clinical Research Network (DRCR.net) at 36 clinical sites in the US reported one case of injection-related endophthalmitis out of 185 injections. In this study 121 patients (109 eligible for analysis) have been randomly assigned to one of five groups: focal photocoagulation at baseline (n=19), intravitreal injection of 1.25 mg bevacizumab at baseline and 6 weeks (n=22), intravitreal injection of 2.5 mg bevacizumab at baseline and 6 weeks (n=24), intravitreal injection of 1.25 mg bevacizumab at baseline and sham injection at 6 weeks (n=22), or intravitreal injection of 1.25 mg bevacizumab at baseline and 6 weeks with photocoagulation at 3 weeks (n=22) (184).

In a Phase II randomized double-masked, sham controlled, trial of pegaptanib sodium for DME one case of endophthalmitis out of a total of 652 injections in 128 pegaptanib subjects occurred. The occurrence rate of endophthalmitis was 0.15% per injection or 0.8% per subject

**EYLEA<sup>®</sup>**  
(Aflibercept)  
EU Risk Management Plan

**Part II – Module SVII: Identified and Potential Risks**

---

assigned to a pegaptanib group. No subject developed endophthalmitis in the sham group (n=42). This 36-week trial enrolled 172 patients with DME from 39 US sites (185).

### **Impact on individual patient**

Endophthalmitis can cause permanent loss of vision if it is not diagnosed at an early stage and appropriately treated. Vision loss as such constitutes a substantial burden for the involved subject.

### **Risk factors and risk groups**

Improper aseptic technique increases the risk of intraocular inflammation.

### **Preventability**

The risk of intraocular inflammation, especially if caused by pathogens, cannot be completely excluded, but may be minimized. In the scope of intravitreal injections of drugs for treatment of wet AMD, CRVO, BRVO, myopic CNV, or DME (by which pathogens might be inadvertently carried into the inner eye), it is absolutely crucial to work under strict aseptic and sterile conditions. Thus, only experienced and appropriately trained ophthalmologists should be charged with the injections.

Moreover, patients should report to their doctors any signs or symptoms of intraocular inflammation (e.g., visual acuity decreased, pain, photophobia, or redness) in order to enable the treating physician to introduce appropriate countermeasures in due time.

### **Impact on the risk-benefit balance of the product**

An educational program is performed as an additional risk minimization measure to raise patients' and physicians' awareness on identified and potential risks. The effectiveness of this program was verified with a post authorization safety study (SN 16526). Furthermore, a specific questionnaire is used to gain more knowledge about this risk.

This important identified risk does not have an impact on the positive risk-benefit balance of Eylea.

### **Public health impact**

Severe intraocular infection/inflammation such as endophthalmitis can cause permanent loss of vision, if it is not rapidly diagnosed and appropriately treated. This condition is likely to impact the ability to work and to increase the dependency on caregivers.

#### **SVII.3.1.2 Identified risk: Intraocular inflammation**

##### **Potential mechanism**

In a certain percentage the intraocular inflammation is culture-negative. However, there are some difficulties in the definition and diagnosis of "sterile" endophthalmitis or intraocular inflammation. Many infectious cases are not diagnosed as such as no tap is performed, or tap is performed, but culture is false negative. Vice versa, true sterile cases may be false positive in culture (e.g., due to contamination of the medium) and thus misdiagnosed as infectious.

The etiology of sterile intraocular inflammations, independently of the administered drug, remains uncertain, and a multifactorial origin has been proposed. Needle trauma *per se* might cause a certain inflammatory reaction. Inflammation secondary both to IVT triamcinolone

**EYLEA<sup>®</sup>**  
(Aflibercept)  
EU Risk Management Plan

**Part II – Module SVII: Identified and Potential Risks**

---

acetone and to IVT bevacizumab (or other anti-VEGF agents) that manifest with acute and painless vision loss is usually interpreted as being primarily toxic and sterile. In these patients, visual acuity improves progressively as the intraocular inflammation reduces without any specific treatment. However, since there remains a substantial uncertainty on origin, the complication is often treated - on top of steroids and NSAID - like an acute (infectious) endophthalmitis with antibiotics because of the devastating visual prognosis of this intraocular infection in the absence of antibiotic therapy (186).

**Evidence source(s) and strength of evidence**

Main reason for considering intraocular inflammation as an important identified risk:

Next to endophthalmitis/intraocular inflammations with an infectious origin, there are inflammations where no pathogens can be identified (either no culture performed or negative culture growth), the condition may be characterized as "sterile" inflammatory condition.

The cause of a sterile inflammation, independently of the administered drug, remains uncertain, and a multifactorial origin cannot be discarded. An intraocular inflammation generally constitutes a serious condition, which may lead to generalized eye inflammation and risk of blindness. Treatment should be initialized as soon as possible, and, depending on cause and severity, may consist of topical and intravitreal application of antibiotics, corticosteroids, and surgical removal of matter and infected structures (drainage, vitrectomy). The proportion of Eylea-exposed patients who experienced intraocular inflammation in the study eye in the clinical studies with Eylea ranged from 0% to 2.6% (VIEW 1 & 2 AMD studies).

Evidence sources: refer to the [linked subsection](#).

MedDRA search terms (version 19.1 for clinical studies and version 20.0 for PM data):

Preferred terms included in search: Anterior chamber cell, anterior chamber fibrin, anterior chamber flare, anterior chamber inflammation, aqueous fibrin, autoimmune uveitis, chorioretinitis, choroiditis, cyclitis, eye inflammation, hypopyon, iridocyclitis, iritis, non-infectious endophthalmitis, non-infective chorioretinitis, pseudoendophthalmitis, uveitis, vitreal cells, vitreous fibrin, and vitritis.

**Characterization of the risk**

**Frequency**

AMD - Pivotal Clinical Trials VIEW 1 and VIEW 2 (pooled data, 96 weeks)

The incidence of intraocular inflammation in the study eye over 96 weeks in the AMD studies VIEW 1 and VIEW 2 was 2.6% and 3.9% in the combined Eylea and in the ranibizumab group, respectively (see [Table SVII.12](#) below).

BRVO Clinical Trial VIBRANT (52 weeks)

One patient experienced intraocular inflammation events in the Phase III study VIBRANT through Week 52: Two events (preferred term: "vitreal cells") occurred in this patient in the Laser+VTE 2 mg group (1.1%; N=92), who was also included in the Eylea total group (0.6%; N=158). The 2 events were mild, non-serious, and resolved.

Myopic CNV Clinical Trial MYRROR (48 weeks)

There was only one patient with intraocular inflammation reported in the MYRROR study through Week 48. This patient was treated in the Eylea 2 mg group (1.1% [N=91] or 0.9% related to N=116 [Eylea total group]). The underlying event (PT: Anterior chamber cell) was non-serious, had a mild severity, and was resolved.

DME - Pivotal Clinical Trials VIVID-DME and VISTA-DME (pooled data, 148 weeks)

The proportion of patients with IOI in the 2 randomized Phase III DME studies up to Week 148 was 1.0% in the laser group and 2.4% in the Eylea total group (see [Table SVII.16](#) below).

<sup>c</sup>: All subjects from any treatment group (incl. laser group; N=243 exposed to additional/PRN treatment with Eylea) who received at least one active Eylea injection in the study eye; counting all AEs which started during or after the first Eylea injection in the study eye through Week 148.

Table Source: Integrated Analysis - EU-RMP Pool 1 (DME), Table 1.5.1/1

#### DME - Clinical Trial VIVID-EAST (52 weeks)

No events pertaining to the group of other intraocular inflammation in the study eye were reported in the VIVID-EAST study.

#### DME - Open-label Clinical Trial VIVID-JAPAN (52 weeks)

In the open-label study VIVID-Japan, one patient was reported to have experienced one intraocular inflammation event (non-serious, mild, and resolved "iritis").

#### Post-Marketing Data

A total of 1,047 cases (including 1,277 events) with IOI terms were reported in the post-marketing environment until 15 SEP 2017 (see following [Table SVII.17](#)). The most commonly reported preferred term events (>100 events) were “eye inflammation” (299 events), “non-infectious endophthalmitis” (295 events), “uveitis” (177 events), and “vitritis” (176 events).

Considering the sales figures and the estimated cumulative patient exposure in the post-marketing period until 30 SEP 2017, the reporting rate of IOI cases (N=1,047) was 0.07 cases per 1,000 sold vials (0.007%) and 0.45 cases per 1,000 patient years (0.045%), respectively. The incidence reported thus far during post-authorization use is within the reported incidence reported in the literature with the IVT injection of anti-VEGF agents and other drugs (see subsequent sections on background incidence and prevalence).

### Seriousness/outcomes

#### AMD - Pivotal Clinical Trials VIEW 1 and VIEW 2 (pooled data, 96 weeks)

Serious IOIs were reported in one patient in the ranibizumab group (resolved non-infectious endophthalmitis; 0.2%) and in one patient in the Eylea 2Q8 group (resolved iridocyclitis; <0.1% of all Eylea-treated patients).

Event outcomes are described in the following [Table SVII.18](#). In 38 patients (2.1%) in the Eylea total group the events were resolved, while 7 patients (0.4%) experienced events that were not resolved (one patient with anterior chamber cell, one patient with anterior chamber flare, 4 patients with vitreal cells, and one patient with vitritis).

EU Risk Management Plan

**Part II – Module SVII: Identified and Potential Risks**

AMD - Clinical Trial ALTAIR (52 weeks)

No events pertaining to the group of intraocular inflammations (excluding likely infectious origin) in the study eye were reported during the course of the ALTAIR study.

CRVO Clinical Trials COPERNICUS and GALILEO (pooled data, 76/100 weeks)

None of the reported IOI events were considered serious. All patients with reports (4 [2.8%] in the Sham+PRN group and 3 [1.4%] in the Eylea 2Q4+PRN group) recovered from their other ocular inflammation events.

BRVO Clinical Trial VIBRANT (52 weeks)

Two IOI events (preferred term: "vitreal cells") occurred in one patient in the Laser+VTE 2 mg group (1.1%; N=92), who was also included in the Eylea total group (0.6%; N=158). Both events were mild, non-serious, and resolved.

Myopic CNV Clinical Trial MYRROR (48 weeks)

There was only one patient with intraocular inflammation reported in the MYRROR study through Week 48. This patient was treated in the Eylea 2 mg group (1.1% [N=91] or 0.9% related to N=116 [Eylea total group]). The underlying event (PT: Anterior chamber cell) was non-serious, had a mild severity, and was resolved.

DME - Pivotal Clinical Trials VIVID-DME and VISTA-DME (pooled data, 148 weeks)

None of the reported intraocular inflammation events in the DME studies up to Week 148 were rated as serious. Event outcomes are provided in the [Table SVII.20](#). In 3 patients, the IOI remained unresolved (see following table; "anterior chamber flare" in one patient in the laser group, "vitreal cells" in another patient in the laser group, and "uveitis" in one patient in the 2Q8 group).

**Table SVII.20: Number of subjects with intraocular inflammation in the study eye by outcome in the pivotal Phase III DME studies from baseline through Week 148 (SAF)**

MedDRA 19.1	Laser <sup>a</sup> n (%)	VTE 2Q4 <sup>b</sup> n (%)	VTE 2Q8 <sup>b</sup> n (%)	VTE total <sup>c</sup> n (%)

<sup>a</sup>: All subjects randomized to initial study eye treatment with active laser.

<sup>b</sup>: All subjects randomized to initial study eye treatment with Eylea (VTE 2Q4 or 2Q8).

<sup>c</sup>: All subjects from any treatment group (incl. laser group; N=243 exposed to additional/PRN treatment with Eylea) who received at least one active Eylea injection in the study eye; counting all AEs which started during or after the first Eylea injection in the study eye through Week 148.

Table Source: Integrated Analysis - EU-RMP Pool 1 (DME), Table 1.5.1/3

DME - Clinical Trial VIVID-EAST (52 weeks)

No events pertaining to the group of other intraocular inflammation in the study eye were reported in the VIVID-EAST study.

**EYLEA<sup>®</sup>**  
(Aflibercept)  
EU Risk Management Plan

**Part II – Module SVII: Identified and Potential Risks**

DME - Open-label Clinical Trial VIVID-JAPAN (52 weeks)

In the open-label study VIVID-JAPAN, one patient was reported to have experienced an intraocular inflammation event (non-serious, mild, and resolved "iritis").

Post-marketing Data

A total of 866 of the 1,277 reported IOI events were regarded as serious (see previous post-marketing table on IOI events).

Reported outcomes were "recovered/resolved" in 520 events, "recovering/resolving" in 129 events, "recovered/resolved with sequelae" in 7 events, and "not recovered/not resolved" in 100 events (missing or unknown outcomes in the remaining 521 events).

**Severity and nature of risk**

AMD - Pivotal Clinical Trials VIEW 1 and VIEW 2 (pooled data, 96 weeks)

Most of the reported events in the ranibizumab group and the Eylea total group had a maximum intensity assessed as "mild" (Table SVII.21). No severe IOIs were reported in the Eylea groups; the 2 severe events reported in 2 patients in the ranibizumab group were hypopyon and non-infectious endophthalmitis.

**Table SVII.21: Number of subjects with intraocular inflammation in the study eye by maximum severity in randomized Phase III wet AMD studies from baseline through Week 96 (SAF)**

#### DME - Clinical Trial VIVID-EAST (52 weeks)

No events pertaining to the group of other intraocular inflammation in the study eye were reported in the VIVID-EAST study.

#### DME - Open-label Clinical Trial VIVID-JAPAN (52 weeks)

In open-label study VIVID-JAPAN, one patient was reported to have experienced an intraocular inflammation event (non-serious, mild, and resolved "iritis").

#### Post-marketing Data

Event severity is not routinely recorded on the post-marketing case report forms.

### **Background incidence/prevalence**

Post-injection, sterile intraocular inflammation is a known risk following intravitreal injections of anti-VEGFs and for other intravitreally applied drugs.<sup>10</sup>

Incidence rates reported in the literature can vary from 0.02% to 0.3% and have been reported to often occur in clusters. In the largest retrospective case series reported to date, Moshfeghi et al. described 12 cases (11 patients) out of 60,322 anti-VEGF injections (bevacizumab n=7; ranibizumab n=5) that developed post-injection inflammation (0.02% per injection) (187). Day et al. conducted a retrospective, longitudinal case-control study using the Medicare 5% claims database. Based on an evaluation of 40,903 intravitreal injections of anti-VEGF agents in wet AMD, an endophthalmitis rate of 0.09% (37 cases) and a uveitis rate of 0.11% (45 cases) were reported (188). Chong et al. reported 44 cases of sterile inflammation after intravitreal injection of bevacizumab (0.27% of 16,166 injections). Seventeen inflammatory

<sup>10</sup> Please consider methodological limitations described in the subsequent section "potential mechanisms".

(Aflibercept)  
EU Risk Management Plan

**Part II – Module SVII: Identified and Potential Risks**

---

reactions were clustered around specific dates, which suggests a possible relation to drug preparation, though a specific cause remains unclear (189).

In Ness et al., a cluster of 10 cases of "toxic vitritis" developed after intravitreal injection of bevacizumab - 6 patients were culture-negative and the remaining 4 were not cultured. The authors attributed these cases to a toxic reaction from the syringe brand used. No further cases occurred after changing to another brand of syringe (190).

Roth et al. described a cluster of 7 patients out of 104 who developed culture negative endophthalmitis, following triamcinolone injection for macula edema. All 7 cases experienced painless, but severe inflammation within 2 days of intravitreal injection (191).

Reports from wet AMD, CRVO, BRVO, myopic CNV, and DME studies

Please see the remarks for previous risk "endophthalmitis".

**Impact on individual patient**

Severe intraocular infection/inflammation can cause permanent loss of vision, if it is not diagnosed at an early stage and appropriately treated. Vision loss as such constitutes a substantial burden for the involved subject.

**Risk factors and risk groups**

Improper aseptic technique increases the risk of intraocular inflammation.

**Preventability**

Measures other than aseptic injection techniques to prevent infectious reactions are not known to minimize the risk of IOI. It is crucial to work under strict aseptic and sterile conditions.

Thus, only experienced and appropriately trained ophthalmologists should be charged with the injection procedure.

Moreover, patients should report to their doctors any signs or symptoms of intraocular inflammation (e.g., visual acuity decreased, pain, photophobia, or redness) as soon as possible in order to enable the treating physician to introduce appropriate countermeasures in due time.

**Impact on risk-benefit balance of the product**

An educational program is performed as an additional risk minimization measure to raise patients' and physicians' awareness on identified and potential risks. The effectiveness of this program was verified with a post authorization safety study (SN 16526). Furthermore, a specific questionnaire is used to gain more knowledge about this risk.

This important identified risk does not have an impact on the positive risk-benefit balance of Eylea.

**Public health impact**

Severe intraocular infection/inflammation can cause permanent loss of vision, if it is not rapidly diagnosed and appropriately treated. This condition is likely to impact the ability to work and to increase the dependency on caregivers.

**SVII.3.1.3 Identified risk: Transient intraocular pressure increase**

**Introductory note:**

**EYLEA<sup>®</sup>**  
(Aflibercept)  
EU Risk Management Plan

**Part II – Module SVII: Identified and Potential Risks**

---

The subsequent analyses are based on the frequency of adverse events coded to the MedDRA preferred terms "intraocular pressure increased" or "ocular hypertension". Inherently, the combined term "intraocular pressure (IOP) increase" does not include information about the duration/persistence of the events. Therefore, the outcome of the adverse events should also be taken into consideration in order to evaluate the occurrence of transient (i.e., "resolved") events of increased intraocular pressure.

### **Potential mechanisms**

Transient IOP increase is attributed to an increase in vitreous volume (volume effect).

### **Evidence source(s) and strength of evidence**

Main reason for considering transient intraocular pressure increase as an important identified risk:

Due to the filling of the eye-ball with liquids (i.e., aqueous and vitreous humor), there is an inherent pressure in the eye, which is measured in the same unit as the blood pressure is (i.e., in millimeter Mercury; mmHg). Normal pressure in the inner eye is approximately 10-21 mmHg. Elevated eye pressure is a major risk factor for a condition called "glaucoma", which is characterized by a loss of nerve fibers in the optic nerve with the subsequent risk of blindness. However, many different factors may be responsible for the development of glaucoma, and increased intraocular pressure is not a mandatory prerequisite for the development of glaucoma (e.g., the condition of normal-tension glaucoma is well-known). In the scope of intravitreal injections, it is easily comprehensible that the volume load caused by the application of the drug, which is dissolved in a certain amount of injection liquid, will lead to a transient increase of intraocular pressure at least until the surplus fluid will have been resorbed from the inner eye.

The proportion of Eylea-exposed patients who experienced an increase in intraocular pressure in the study eye in the clinical studies with Eylea ranged from 2.8% (VIVID-JAPAN DME study) to 13.6% (CRVO studies GALILEO & COPERNICUS).

Evidence sources: refer to the [linked subsection](#).

MedDRA search terms (version 19.1 for clinical studies and version 20.0 for PM data):

Preferred terms included in search: Intraocular pressure increased, ocular hypertension.

### **Characterization of the risk**

#### **Frequency**

AMD - Pivotal Clinical Trials VIEW 1 and VIEW 2 (pooled data, 96 weeks)

AEs of increased IOP in the study eye occurred in 66 patients (11.1%) who were treated with ranibizumab, compared to 142 patients (7.8%) in the combined group of patients treated with Eylea during the 96 weeks treatment period in the VIEW 1 and VIEW 2 studies (see [Table SVII.24](#)).

Myopic CNV Clinical Trial MYRROR (48 weeks)

No adverse events of increased intraocular pressure in the study eye were reported in the period from baseline through Week 48.

DME - Pivotal Clinical Trials VIVID-DME and VISTA-DME (pooled data, 148 weeks)

The incidence of the adverse events related to "intraocular pressure increased" in the study eye through Week 148 was 8.0% of patients in the laser group, 18.2% of patients in the Eylea 2Q4 group, and 10.8% of patients in the Eylea 2Q8 group (Table SVII.29). Thus, the incidence was numerically slightly higher in the Eylea groups compared to the laser group, which is consistent with the procedure-related effects of IVT Eylea administration. Among all patients who had received Eylea at least once (Eylea total group), the frequency of the AEs related to "intraocular pressure increased" after treatment initiation with Eylea was 12.2%.

<sup>a</sup>: All subjects randomized to initial study eye treatment with active laser.

<sup>b</sup>: All subjects randomized to initial study eye treatment with Eylea (VTE 2Q4 or 2Q8).

<sup>c</sup>: All subjects from any treatment group (incl. laser group; N=45 exposed to Eylea) who received at least one active Eylea injection in the study eye; counting all AEs which started during or after the first Eylea injection in the study eye through Week 52.

Table Source: Integrated Analysis - EU-RMP Pool 1 (DME), Table 1.5.3/1

DME - Open-label Clinical Trial VIVID-JAPAN (52 weeks)

In the open-label Phase III study VIVID-JAPAN, a total of 2 subjects (2.8% of the 72 SAF subjects) experienced at least one treatment-emergent adverse event of "intraocular pressure increased" in the study eye through Week 52.

Post-marketing Data

By 15-SEP-2017, a total of 250 cases with 260 events pertaining to the grouping "increased ocular pressure" were reported in the pharmacovigilance database ([Table SVII.31](#)).

Considering the sales figures and the estimated cumulative patient exposure in the post-marketing period until 30 SEP 2017, the reporting rate of cases associated with IOP increase (N=250) was 0.02 cases per 1,000 sold vials (0.002%) and 0.11 cases per 1,000 patient years (0.011%), respectively.

**Table SVII.31: Number of post-marketing events of increased intraocular pressure by 15 SEP 2017**

<b>Group: IOP increase</b>	<b>250 cases</b>		
<b>Grouped preferred terms *:</b>	<b>Non-serious</b>	<b>Serious</b>	<b>All</b>
Intraocular pressure increased	143	95	238
Ocular hypertension	11	11	22
<b>Total number of events</b>	<b>154</b>	<b>106</b>	<b>260</b>

### Seriousness/outcomes

#### AMD - Pivotal Clinical Trials VIEW 1 and VIEW 2 (pooled data, 96 weeks)

There were few serious cases of the AE IOP increase; thus, the frequency was low and very similar across all treatment groups (0.2% in the combined Eylea group; [Table SVII.32](#)).

**Table SVII.32: Number of subjects with serious increased intraocular pressure in the study eye (grouped term and included preferred terms) in randomized Phase III wet AMD studies from baseline through Week 96 (SAF)**

Table Source: Integrated Analysis - EU-RMP Pool 1 (AMD), Table 1.1.1/3

#### AMD - VIEW 1 long-term extension study

One event in one patient was serious (0.4% of patients in the former Eylea groups [N=254]; PT: intraocular pressure increased). This event was also regarded as severe; the event outcome was "recovered/resolved".

Overall, most of the events (in 12 patients) were resolved, while in 4 patients the events remained unresolved ([Table SVII.34](#)).

<sup>c</sup>: All patients who were treated with Eylea in the extension study period. Only AEs occurring after the first active Eylea injection were counted.

Note: Events that occurred in the VIEW 1 core study are not considered.

Table Source: Integrated Analysis - EU-RMP Pool 1 (AMD), Table 1.1.2/3

AMD - Clinical Trial SIGHT (52 weeks)

All reported cases of increased IOP in the study eye (see preceding frequency table) were non-serious (and mild), and all 17 involved patients recovered.

AMD - Clinical Trial ALTAIR (52 weeks)

No events pertaining to the group of intraocular pressure increase in the study eye were reported during the course of the ALTAIR study.

CRVO Clinical Trials COPERNICUS and GALILEO (pooled data, 76/100 weeks)

No IOP events were considered serious in the CRVO trials. Of the 43 subjects with an AE of increased IOP in the Eylea total group, 31 were recovered, whilst 11 subjects remained not recovered (missing information in one patient, [Table SVII.35](#)).

**Table SVII.35: Number of subjects with increased intraocular pressure in the study eye by outcome in the Phase III CRVO studies from baseline through Week 76/100 (SAF)**

Myopic CNV Clinical Trial MYRROR (48 weeks)

No adverse events of increased intraocular pressure in the study eye were reported in the period from baseline through Week 48.

DME - Pivotal Clinical Trials VIVID-DME and VISTA-DME (pooled data, 148 weeks)

Only one event of increased intraocular pressure was considered serious in the pivotal DME trials through Week 148. This event occurred post-injection in one patient in the Eylea 2Q8 group (0.1% of the 821 patients who had received Eylea at least once).

The outcome of the reported events is summarized in the following [Table SVII.37](#). The IOP increase was "resolved" (88 subjects) in the majority of the 100 subjects in the total Eylea group, whereas 8 patients did not recover. Overall, most of the reported adverse events of intraocular pressure increase were obviously transient.

DME - Open-label Clinical Trial VIVID-JAPAN (52 weeks)

In the open-label Phase III study VIVID-JAPAN, both events of "intraocular pressure increased" in the study eye were regarded as mild and non-serious. The outcome was "recovered/resolved" in one case and "recovering/resolving" in the other case.

Post-marketing Data

A total of 106 out of the 260 reported events of increased IOP were regarded as serious (see previous post-marketing table on IOP events).

**EYLEA<sup>®</sup>**  
(Aflibercept)  
EU Risk Management Plan

**Part II – Module SVII: Identified and Potential Risks**

Reported outcomes were "recovered/resolved" in 88 events, "recovering/resolving" in 31 events, and "not recovered/not resolved" in 28 events (missing or unknown outcomes in the remaining 113 events).

**Severity and nature of risk**

AMD - Pivotal Clinical Trials VIEW 1 and VIEW 2 (pooled data, 96 weeks)

The majority of the cases of increased IOP were of mild severity across all treatment groups (Table SVII.39). There were few cases of severely increased IOP, accounting for 0.3% of all patients in both the ranibizumab and the combined Eylea group.

**Table SVII.39: Number of subjects with increased intraocular pressure in the study eye by maximum severity in randomized Phase III wet AMD studies from baseline through Week 96 (SAF)**

#### DME - Open-label Clinical Trial VIVID-JAPAN (52 weeks)

Both events of "intraocular pressure increased" in the study eye were regarded as mild (and non-serious).

#### Post-marketing Data

Event severity is not routinely recorded on the post-marketing case report forms.

### **Background incidence/prevalence**

#### AMD/CRVO

No publications on transient intraocular pressure increase due to study disease were identified.

#### BRVO

In the following three out of five clinical trials involving BRVO subjects no intra-ocular pressure (IOP) increase was reported:

Campochiaro et al. 2010 (192) (ranibizumab 0.3 mg or 0.5 mg vs. sham treatment), Russo et al. 2009 (177) (Bevacizumab compared with macular laser grid photocoagulation), and Donati et al. 2012 (179) (combined intravitreal bevacizumab and grid laser photocoagulation).

In SCORE–BRVO 2009 (122) (intravitreal triamcinolone vs. standard of care), IOP increase requiring medication was observed in 2%, 8%, and 41% in the standard of care group, 1 mg triamcinolone group, and 4 mg triamcinolone group, respectively. IOP >10 mmHg was observed in the 4 mg triamcinolone group (36%) compared with the 1 mg triamcinolone (9%) and standard of care (3%) group.

Parodi et al. 2008 (178) (intravitreal triamcinolone acetonide combined with sub-threshold grid laser treatment compared to simple laser grid) described an increase in IOP in 54% of the 24 study patients, which required treatment.

---

### Myopic CNV

A prospective study (Gharbiya et al. 2009) to evaluate the short-term efficacy and safety of intravitreal bevacizumab for the treatment of myopic CNV was conducted in Italy on 20 patients. At month 12 follow-up, no significant intraocular pressure (IOP) changes in the treated eyes were observed: mean IOP values ( $\pm$  SD) at baseline and at month 12 were respectively 14.2 ( $\pm$  2.21) mm Hg and 13.75 ( $\pm$  2.46) mm Hg ( $p=0.35$ ) (193).

An open-label study (Ikuno et al. 2010) to compare the long-term visual and anatomic outcome of treatment with photodynamic therapy or intravitreal bevacizumab for myopic CNV was conducted on 31 eyes of Japanese women. No transient IOP increase was reported (194).

Another retrospective study of 63 patients conducted in Japan by the same investigator (Ikuno et al. 2009) aimed at assessing the potential effect of intravitreal bevacizumab on retinal function and anatomic recovery in eyes with myopic CNV. No IOP increase was reported (195).

In a prospective study (Osaka University) to compare the visual outcomes of intravitreal bevacizumab and sub-Tenon triamcinolone acetonide (TA) for choroidal neovascularization attributable to myopic CNV, 53 patients participated. In the sub-Tenon TA group, 3 eyes (15%) had an IOP of more than 21 mm Hg that was managed with antiglaucoma medications (196).

### DME

In a Phase III controlled study, 197 patients with diabetic macular edema were randomized to receive a fluocinolone 0.5 mg implant, or standard of care (macular grid laser/observation). Glaucoma was reported in 9% of patients treated with the fluocinolone implant and in 0% of patients treated with photocoagulation. The study did not describe transient IOP increases (197).

A Korean study compared the efficacy of posterior sub-Tenon's capsule triamcinolone acetonide injection combined with modified grid macular photocoagulation (PSTI + MP) with intravitreal triamcinolone acetonide (IVTA) injection in the treatment of diffuse DME. Forty eyes of 33 patients with diffuse DME were randomly allocated to either treatment. IOP was measured using a Goldman applanation tonometer. Between-group comparisons revealed significant differences in mean IOP changes at 1 month and 3 months ( $p = 0.006$ ,  $p = 0.026$ , respectively). Three of 20 (15%) eyes in the IVTA group developed IOP elevation which exceeded 21 mmHg; and this was controlled with topical anti-glaucomatous agents. The 3 eyes with elevated IOP belonged to three different patients. No eye that received a posterior sub-Tenon injection developed increased IOP exceeding 21 mmHg (198).

Two 24 month, parallel, methodologically identical, randomized, multicenter, double-masked, sham injection-controlled, Phase III studies (RISE and RIDE) to evaluate efficacy and safety of intravitreal ranibizumab in DME. In RISE, 377 patients were randomized to either ranibizumab (n=125 to 0.3mg and n=125 to 0.5mg) or sham injection (n=127) out of which no case of increased IOP was reported in RISE study. In RIDE, 382 patients were randomized to either ranibizumab (n=125 to 0.3mg and n=127 to 0.5mg) or sham injection (n=130) out of which one case of increased IOP occurred in the 0.5mg ranibizumab treatment group (0.8%) and no case of increased IOP was reported in 0.3mg ranibizumab and sham group. The study

**EYLEA<sup>®</sup>**  
(Aflibercept)  
EU Risk Management Plan

**Part II – Module SVII: Identified and Potential Risks**

---

did not specify if the increase in IOP was transient, but the event was considered a serious adverse event (128).

A 12-month, randomized, sham controlled, double-masked, multicenter Phase II study of safety and efficacy of ranibizumab in DME with center involvement (RESOLVE Study) enrolled 151 subjects to either ranibizumab (0.3 to 0.6 mg, n=51; or 0.5 to 1mg, n =51) or sham treatment (n=49). Six cases of transient IOP increase were reported in 0.3 to 0.6mg ranibizumab treatment group (11.8%) and 15 cases of transient IOP increase were reported in 0.5 to 1mg ranibizumab treatment group (29.4%) and one case of transient IOP increase in sham group (2%) (129).

A 12-month, randomized, laser controlled, double masked, multicenter Phase III study to demonstrate superiority of ranibizumab 0.5 mg monotherapy or combined with laser over laser alone in DME patients (RESTORE study). 345 patients were randomized to ranibizumab + sham laser (n = 116), ranibizumab + laser (n = 118), or sham injections + laser (n = 111). One patient each in ranibizumab arms experienced IOP increase and none in sham group. Both cases of IOP resolved on their own and investigator related it to the injection procedure and not to the drug (183).

### **Impact of individual patient**

Transient IOP increase is usually a mild reaction which is compensated within 0.5 – 1 hrs after injection so that IOP normalizes back to baseline values. Patients recovered without sequelae (162), (160).

### **Risk factors and risk groups**

Patients with glaucoma.

Increased intraocular pressure is a known adverse drug reaction on treatment with intravitreal corticosteroids.

### **Preventability**

Intraocular pressure should be checked after each injection. As the transient increase of eye pressure is an inherent result of the procedure-related volume load in the scope of intravitreal injections, there is no reasonable chance to avoid this effect. However, this effect is usually transient, and there is no robust evidence so far that pressure increases following intravitreal injections (even after multiple injections) could become durable or may lead to clinically relevant glaucoma.

### **Impact on the risk-benefit balance of the product**

An educational program is performed as an additional risk minimization measure to raise patients' and physicians' awareness on identified and potential risks. The effectiveness of this program was verified with a post authorization safety study (SN 16526). Furthermore, a specific questionnaire is used to gain more knowledge about this risk (currently under review).

This important identified risk does not have an impact on the positive risk-benefit balance of Eylea.

**EYLEA<sup>®</sup>**  
(Aflibercept)  
EU Risk Management Plan

**Part II – Module SVII: Identified and Potential Risks**

## Public health impact

Due to the transient and usually mild nature of the condition, no impact of this safety concern on public health issues is expected.

### SVII.3.1.4 Identified risk: Retinal pigment epithelial tear

#### Potential mechanisms

Development of RPE tears after anti-VEGF intravitreal injection has been attributed to a decline in intercellular adherence, thereby increasing susceptibility to tearing of the RPE layer (199).

#### Evidence source(s) and strength of evidence

Main reason for considering retinal pigment epithelial tear as an important identified risk:

The retinal pigment epithelium is the outer layer of the retina. Tears in that layer may occur secondary to AMD, following intravitreal injections, or for unknown reasons. These tears may be self-sealing or may require sealing by laser coagulation.

In clinical trials up to 1.9% of patients with underlying wet AMD who were treated with Eylea developed a tear of the outer layer of the retina, whilst none of the patients with underlying CRVO, BRVO, myopic CNV, or DME developed a tear of the outer layer of the retina.

Evidence sources: refer to the [linked subsection](#).

MedDRA search terms (version 19.1 for clinical studies and version 20.0 for PM data):

Preferred term: Retinal pigment epithelial tear.

#### Characterization of the risk

##### Frequency

AMD - Pivotal Clinical Trials VIEW 1 and VIEW 2 (pooled data, 96 weeks)

Retinal pigment epithelial (RPE) tears occurred in 1.9% of all patients treated with Eylea, compared to 1.5% of patients in the ranibizumab group (see [Table SVII.45](#)).

**Table SVII.45: Number of subjects with retinal pigment epithelium tears in the study eye in randomized Phase III wet AMD studies from baseline through Week 96 (SAF)**

MedDRA 19.1	Ranibizumab		Eylea		Total n (%)
	Q4 n (%)	2 mg Q4 n (%)	0.5 mg Q4 n (%)	2 mg Q8 n (%)	
Number of subjects	595	613	601	610	1,824
Preferred term					
RPE tear	9 (1.5)	5 (0.8)	10 (1.7)	20 (3.3)	35 (1.9)

Q4 = every 4 weeks, Q8 = every 8 weeks

Note: No grouping of preferred terms was performed.

Table Source: Integrated Analysis - EU-RMP Pool 1 (AMD), Table 1.1.1/1

(Aflibercept)  
EU Risk Management Plan

**Part II – Module SVII: Identified and Potential Risks**

---

AMD - VIEW 1 long-term extension study

Two patients (0.6% of all 323 patients treated with Eylea) experienced RPE tears in the study eye during the extension period (one patient in former randomized ranibizumab group [1.4%] and one patient in former randomized Eylea groups [0.4%]). There were no meaningful differences compared with the frequency of RPE tears reported from the pivotal AMD trials through Week 96 (see preceding [Table SVII.45](#)).

AMD - Clinical Trial SIGHT (52 weeks)

Cases of RPE tears were infrequent in the SIGHT study, since only one patient in the Eylea 2Q8 group was involved (0.4% based on 228 patients randomized to the 2Q8 group or 0.3% based on the 299 Eylea-exposed patients). This event was mild, non-serious, and not resolved.

AMD - Clinical Trial ALTAIR (52 weeks)

Cases of RPE tears were infrequent in the ALTAIR study, since only 3 patients in the 2W adjustment group experienced RPE tears (2.4% based on 124 patients randomized to the 2W adjustment group or 1.2% based on the 254 Eylea-exposed patients).

CRVO Clinical Trials COPERNICUS and GALILEO (pooled data, 76/100 weeks)

No cases of RPE tears were reported in the CRVO trials.

BRVO Clinical Trial VIBRANT (52 weeks)

No cases of RPE tears were reported in the BRVO study VIBRANT through Week 52.

Myopic CNV Clinical Trial MYRROR (48 weeks)

No cases of RPE tears were reported in the period from baseline through Week 48.

DME - Pivotal Clinical Trials VIVID-DME and VISTA-DME (pooled data, 148 weeks)

Please note that RPE tears is a phenomenon that occurs particularly in AMD patients. However, it has been included as important identified risk, since the RMP covers all indications. As with CRVO, BRVO, and myopic CNV, no cases of RPE tears in the study eye were reported in the DME trials through Week 148.

DME - Clinical Trial VIVID-EAST (52 weeks)

No cases of RPE tears in the study eye were reported in VIVID-EAST.

DME - Open-label Clinical Trial VIVID-JAPAN (52 weeks)

No cases of RPE tears in the study eye were reported in VIVID-JAPAN.

Post-marketing Data

As of 15 SEP 2017, a total of 159 cases (with 163 events) with RPE tear were reported in the pharmacovigilance database. All but 10 events were considered serious.

Considering the sales figures and the estimated cumulative patient exposure in the post-marketing period until 30-SEP-2017, the reporting rate of "RPE tear" cases (N=159) was 0.01 cases per 1,000 sold vials (0.001%) and 0.07 cases per 1,000 patient years (0.007%), respectively.

### Seriousness/outcomes

#### AMD - Pivotal Clinical Trials VIEW 1 and VIEW 2 (pooled data, 96 weeks)

The rate of patients with serious treatment-emergent RPE tears was 0.2% in both the ranibizumab and the combined Eylea group (corresponding to one patient treated with ranibizumab and 4 patients treated with Eylea) (Table SVII.46).

**Table SVII.46: Number of subjects with serious retinal pigment epithelium tears in the study eye in randomized Phase III wet AMD studies from baseline through Week 96 (SAF)**

MedDRA 19.1	Ranibizumab		Eylea		Total n (%)
	Q4 n (%)	2 mg Q4 n (%)	0.5 mg Q4 n (%)	2 mg Q8 n (%)	
Number of subjects	595	613	601	610	1,824
Preferred term					
RPE tear	1 (0.2)	0	1 (0.2)	3 (0.5)	4 (0.2)

Q4 = every 4 weeks, Q8 = every 8 weeks

Note: No grouping of preferred terms was performed.

Table Source: Integrated Analysis - EU-RMP Pool 1 (AMD), Table 1.1.1/4

RPE tears remained unresolved until the end of the study in the majority of affected patients in any treatment group (Table SVII.47).

**Table SVII.47: Number of subjects with retinal pigment epithelium tears by outcome in randomized Phase III wet AMD studies from baseline through Week 96 (SAF)**

MedDRA 19.1	Ranibizumab		Eylea		Total n (%)
	Q4 n (%)	2 mg Q4 n (%)	0.5 mg Q4 n (%)	2 mg Q8 n (%)	
Number of subjects	595	613	601	610	1,824
Preferred term					
RPE tear	9 (1.5)	5 (0.8)	10 (1.7)	20 (3.3)	35 (1.9)
Outcome

Unknown	0	1 (0.2)	0	0	1 (<0.1)
Not recovered / not resolved	6 (1.0)	4 (0.7)	9 (1.5)	15 (2.5)	28 (1.5)

Q4 = every 4 weeks, Q8 = every 8 weeks

Note: For each subject, only the adverse event with the worst outcome is counted within each safety topic class and overall.

Note: No grouping of preferred terms was performed.

Table Source: Integrated Analysis - EU-RMP Pool 1 (AMD), Table 1.1.1/3

#### AMD - VIEW 1 long-term extension study

Two patients (0.6% of all 323 patients treated with Eylea) experienced RPE tears in the study eye during the extension period (one patient in former randomized ranibizumab group [1.4%] and one patient in former randomized Eylea groups [0.4%]). Both events were non-serious and mild, but the patients were not recovered from that event.

**EYLEA<sup>®</sup>**  
(Aflibercept)  
EU Risk Management Plan

**Part II – Module SVII: Identified and Potential Risks**

---

AMD - Clinical Trial SIGHT (52 weeks)

The only reported event of RPE tears (occurring in one patient in the Eylea 2Q8 group) was non-serious, mild, and not resolved.

AMD - Clinical Trial ALTAIR (52 weeks)

3 cases of RPE tears were reported (occurring in the 2W adjustment group), in 2 of them the outcome was unknown, in one case not recovered. None of these cases was serious.

CRVO Clinical Trials COPERNICUS and GALILEO (pooled data, 76/100 weeks)

No cases of RPE tears were reported in the CRVO trials.

BRVO Clinical Trial VIBRANT (52 weeks)

No cases of RPE tears were reported in the BRVO study VIBRANT through Week 52.

Myopic CNV Clinical Trial MYRROR (48 weeks)

No cases of RPE tears were reported in the period from baseline through Week 48.

DME - Pivotal Clinical Trials VIVID-DME and VISTA-DME (pooled data, 148 weeks)

No cases of RPE tears in the study eye were reported in the DME trials through Week 148.

DME - Clinical Trial VIVID-EAST (52 weeks)

No cases of RPE tears in the study eye were reported in VIVID-EAST.

DME - Open-label Clinical Trial VIVID-JAPAN (52 weeks)

No cases of RPE tears in the study eye were reported in VIVID-JAPAN.

Post-marketing Data

Ten of the 148 reported events of RPE tears were considered non-serious, whilst 153 events were serious.

Reported outcomes were "recovered/resolved" in 8 events, "recovering/resolving" in 8 events, "recovered/resolved with sequelae" in 10 events, and "not recovered/not resolved" in 77 events (missing or unknown outcomes in the remaining 60 events).

**Severity and nature of risk**

AMD - Pivotal Clinical Trials VIEW 1 and VIEW 2 (pooled data, 96 weeks)

Except for 2 patients with severe events (one patient each on ranibizumab or Eylea), RPE tears were of mild or moderate intensity ([Table SVII.48](#)).

**EYLEA<sup>®</sup>**  
(Aflibercept)  
EU Risk Management Plan

**Part II – Module SVII: Identified and Potential Risks**

**Table SVII.48: Number of subjects with retinal pigment epithelium tears by maximum severity in randomized Phase III wet AMD studies from baseline through Week 96 (SAF)**

---

DME - Open-label Clinical Trial VIVID-JAPAN (52 weeks)

No cases of RPE tears in the study eye were reported in VIVID-JAPAN.

Post-marketing Data

Event severity is not routinely recorded on the post-marketing case report forms.

**Background incidence/prevalence**

AMD:

RPE tears have been reported in patients with wet AMD in the absence of treatment, particularly when a pigment epithelial detachment (PED) is present. Incidence rates for spontaneous RPE tears ranged between 2-6% of eyes with AMD (200), (201), (202) and between 10-25% in eyes with AMD and pigment epithelial detachments (PED) (202). The most important predisposing risk factor appears to be PED size as measured by basal diameter (201) and vertical height (200), (17). Also, eyes with serious RPE detachment appear to be more vulnerable to RPE tears (203).

CRVO:

No data identified.

BRVO:

No findings were identified. All reviewed BRVO studies did not report any RPE tears.

Myopic CNV:

In the Osaka University study, 114 of the 707 participants were myopic CNV patients. There were no reports of RPE tears among them (204).

In a consecutive prospective study to determine the efficacy and safety of intravitreal bevacizumab in the treatment of CNV secondary to pathological myopia 17 patients participated. During a six months follow-up one RPE tear was reported after the first injection (205).

No findings of RPE tears were reported in the two studies by Ikuno et al. (195), (194) and Gharbiya et al. 2009 (193), and the rest of the reviewed publications.

DME:

No data identified.

Additional considerations on RPE tears as class effect:

RPE tears have also been reported following treatment of the neovascularization, regardless of whether the treatment was delivered intravitreally (pegaptanib sodium, bevacizumab, ranibizumab) or through other means (argon or krypton laser photocoagulation, transpupillary thermotherapy, photodynamic therapy with verteporfin) (161), (206), (207), (208), (209), (210), (211), (212), (213), (214), (215), (158).

Development of RPE tears after anti-VEGF intravitreal injection has been attributed to a decline in intercellular adherence, thereby increasing susceptibility to tearing of the RPE layer (199).

The incidence of RPE tears during ranibizumab treatment was 0.4% (165).

**EYLEA<sup>®</sup>**  
(Aflibercept)  
EU Risk Management Plan

**Part II – Module SVII: Identified and Potential Risks**

---

Salz et al. (202) concluded in their review that the overall incidence of RPE tears in eyes with wet AMD was similar regardless of whether an anti-VEGF agent was used, and that patients receiving anti-VEGF therapy were more likely to develop a tear earlier than untreated patients, most probably related to the accelerated involution induced by VEGF inhibition.

According to Chang and Seraf (201), all cases of RPE tear associated with anti-VEGF treatment occurred in the setting of wet AMD. Information on RPE in the CRVO population from the published literature is scarce. Below are some findings:

Data from a study of 707 patients (1,300 injections) who visited Osaka University Hospital, Japan, and received one or repeated IVT injections of bevacizumab were reviewed. Each patient was followed for AEs for two months post injections. No cases of RPE were reported among the 88 CRVO/BRVO patients. The one reported case of RPE occurred in a patient with AMD (216) (204).

Overall, the total incidence of RPE tears with Eylea in the AMD Phase III trials was in line with the known background incidences from literature; no RPE tears occurred in the CRVO/BRVO studies, in the myopic CNV study, or in the DME studies through Week 148. The promotion of RPE tear development by IVT treatment with Eylea is, therefore, deemed unlikely.

### **Impact on individual patients**

RPE tears may lead to a loss of vision (and thus to legal blindness).

### **Risk factors and risk groups**

Wet AMD with pigment epithelial detachment; treatment of neovascularization.

### **Preventability**

The underlying mechanisms resulting in RPE tears following intravitreal injection are not yet understood and thus, no preventive measure is currently known.

### **Impact on risk-benefit balance of the product**

An educational program is performed as an additional risk minimization measure to raise patients' and physicians' awareness on identified and potential risks. The effectiveness of this program was verified with a post authorization safety study (SN 16526).

This important identified risk does not have an impact on the positive risk-benefit balance of Eylea.

### **Public health impact**

The potential public health impact of this safety concern is considered to be low, due to the low frequency of serious or severe events in clinical trials.

## **SVII.3.1.5 Identified risk: Cataract (especially of traumatic origin)**

### **Potential mechanisms**

Related to IVT procedure.

**EYLEA<sup>®</sup>**  
(Aflibercept)  
EU Risk Management Plan

**Part II – Module SVII: Identified and Potential Risks**

---

**Evidence source(s) and strength of evidence**

Main reason for considering cataract (especially of traumatic origin) as an important identified risk:

Generally, clouding of the usually clear eye lens is called a cataract. Cataract may occur spontaneously (particularly in the elderly), as a side effect of certain drugs, or following outside influences such as irradiation or mechanical injury (traumatic cataract).

If the needle used to inject Eylea touched the lens in the patient's eye this could cause such a traumatic cataract. There is currently no evidence that the occurrence of a traumatic cataract is increased on treatment with Eylea. However, as this might be a hypothetical result of the lens perforation, it has been included as potential important risk.

The proportion of Eylea-exposed patients who experienced traumatic cataract in the study eye in the clinical studies with Eylea ranged from 0% to 2.8% (VIVID-DME & VISTA-DME).

Evidence sources: refer to the [linked subsection](#).

MedDRA search terms (version 19.1 for clinical studies and version 20.0 for PM data):

Preferred terms included in search: Atopic cataract, cataract, cataract cortical, cataract diabetic, cataract nuclear, cataract operation, cataract subcapsular, cataract traumatic, intraocular lens implant, lens capsulotomy, lens discolouration, lens extraction, lenticular injury, lenticular opacities, lenticular operation, posterior lens capsulotomy, radiation cataract, and toxic cataract.

**Characterization of the risk:**

**Frequency**

AMD - Pivotal Clinical Trials VIEW 1 and VIEW 2 (pooled data, 96 weeks)

*All cataracts:*

The 96 weeks overall cataract incidence including all terms from the search strategy was 12.8% of patients in the combined Eylea group and 10.4% in the ranibizumab group regardless of association to the injection-procedure ([Table SVII.49](#)). This incidence of cataracts is in line with background incidences as derived from literature and as seen in control arms from clinical trials with other anti-VEGF therapies (see background incidences below).

Lenticular opacities	0	1 (0.4)	1 (0.3)

<sup>a</sup>: Patients who were randomized to treatment with ranibizumab in the VIEW 1 core study.

<sup>b</sup>: Patients who were randomized to treatment with Eylea (0.5Q4, 2Q4, or 2Q8) in the VIEW 1 core study.

<sup>c</sup>: All patients who were treated with Eylea in the extension study period. Only AEs occurring after the first active Eylea injection were counted.

Note: Events that occurred in the VIEW 1 core study are not considered.

Table Source: Integrated Analysis - EU-RMP Pool 1 (AMD), Table 1.1.2/1

*Injection-related (traumatic) cataracts:*

No injection-related cataracts were reported during the extension period.

AMD - Clinical Trial SIGHT (52 weeks)

*All cataracts:*

Any cataracts in the study eye were reported in 3 patients (3.9%) in the PDT+VTE 2 mg group and in 10 patients (4.4%) in the VTE 2Q8 group (12 patients [4.0%] in the Eylea total group; see [Table SVII.52](#)).

**EYLEA<sup>®</sup>**  
(Aflibercept)  
EU Risk Management Plan

**Part II – Module SVII: Identified and Potential Risks**

**Table SVII.52: Number of subjects with any cataract in the study eye (grouped term and included preferred terms) in the Phase III AMD study SIGHT from baseline through Week 52 (SAF)**

MedDRA 19.1	PDT + VTE 2mg <sup>a</sup> n (%)	VTE 2Q8 <sup>b</sup> n (%)	VTE total <sup>c</sup> n (%)
Number of subjects	76	228	299
Grouped term			
Cataract	3 (3.9)	10 (4.4)	12 (4.0)
Included preferred terms			
Cataract	1 (1.3)	2 (0.9)	3 (1.0)
Cataract cortical	0	3 (1.3)	3 (1.0)
Lenticular opacities	2 (2.6)	5 (2.2)	6 (2.0)

<sup>a</sup>: PDT + sham injections until Wk. 24, afterwards VTE 2 mg at Wks. 28, 32, 36, 40, and 48.

<sup>b</sup>: First 3 injections with VTE 2Q4, followed by VTE 2Q8 until Wk. 48 (sham PDT until Wk. 24).

<sup>c</sup>: All patients exposed to Eylea. Only TEAEs occurring after first exposure are considered.

Table Source: Integrated Analysis - EU-RMP Pool 1 (AMD), Table 1.1.3/1

*Injection-related (traumatic) cataracts:*

Injection-related cataracts in the study eye were reported in one patient (1.3%) in the PDT+VTE 2 mg group and in 2 patients (0.9%) in the VTE 2Q8 group (3 patients [1.0%] in the Eylea total group; see [Table SVII.53](#)). Thus, the rate of traumatic cataract was small and similar in the 2 treatment groups.

**Table SVII.53: Number of subjects with injection-related (traumatic) cataract in the study eye (grouped term and included preferred terms) in the Phase III AMD study SIGHT from baseline through Week 52 (SAF)**

MedDRA 19.1	PDT + VTE 2mg <sup>a</sup> n (%)	VTE 2Q8 <sup>b</sup> n (%)	VTE total <sup>c</sup> n (%)

Cataract	1 (1.3)	2 (0.9)	3 (1.0)

<sup>a</sup>: PDT + sham injections until Wk. 24, afterwards VTE 2 mg at Wks. 28, 32, 36, 40, and 48.

<sup>b</sup>: First 3 injections with VTE 2Q4, followed by VTE 2Q8 until Wk. 48 (sham PDT until Wk. 24).

<sup>c</sup>: All patients exposed to Eylea. Only TEAEs occurring after first exposure are considered.

Table Source: Integrated Analysis - EU-RMP Pool 1 (AMD), Table 1.1.3/1

AMD - Clinical Trial ALTAIR (52 weeks)

*All cataracts:*

Cases of cataract were infrequent in the ALTAIR study, since only 2 patients in the 2W adjustment group and 1 patient in the 4W adjustment group experienced such events (1.6% based on 124 patients randomized to the 2W adjustment group or 0.8% based on 123 patients randomized to the 4W adjustment group or 1.2% based on the 254 Eylea-exposed patients).

*Injection-related cataracts:*

No injection-related cataracts were reported in ALTAIR through week 52.

**EYLEA<sup>®</sup>**  
(Aflibercept)  
EU Risk Management Plan

**Part II – Module SVII: Identified and Potential Risks**

CRVO Clinical Trials COPERNICUS and GALILEO (pooled data, 76/100 weeks)

*All cataracts:*

Cataracts in the study eye occurred in 7.6% of patients on Eylea treatment (24 patients, [Table SVII.54](#)). The incidence was higher in the Eylea 2Q4+PRN group than in the Sham+PRN group (9.2% vs. 4.9%) but, in view of the small absolute number of events, no clinically meaningful differences were observed between the 2 randomized treatment groups.

**Table SVII.54: Number of subjects with cataract in the study eye (grouped term and included preferred terms) in the Phase III CRVO studies from baseline through Week 76/100 (SAF)**

MedDRA 19.1	Sham + PRN n (%)	VTE 2Q4 + PRN n (%)	Eylea total <sup>a</sup> n (%)

**EYLEA<sup>®</sup>**  
(Aflibercept)  
EU Risk Management Plan

**Part II – Module SVII: Identified and Potential Risks**

*Injection-related (traumatic) cataracts:*

One case of cataract (preferred term: "cataract traumatic") was regarded as injection-related (i.e., traumatic). This event occurred in the VTE 2 mg group.

Myopic CNV Clinical Trial MYRROR (48 weeks)

*All cataracts:*

There was only one patient with cataract reported in the MYRROR study through Week 48. This patient was treated in the Eylea 2 mg group (1.1% [N=91] or 0.9% related to N=116 [Eylea total group]). The underlying event (PT: Cataract subcapsular) was non-serious and had a mild severity but was not resolved.

*Injection-related (traumatic) cataracts:*

No injection-related (i.e., traumatic) cataracts were reported in MYRROR through Week 48.

DME - Pivotal Clinical Trials VIVID-DME and VISTA-DME (pooled data, 148 weeks)

*All cataracts:*

The proportions of patients with any cataract through Week 148 were 23.3% in the laser group, 30.2% in the 2Q4 group, 23.3% in the 2Q8 group, and 22.9% among the 821 study patients who were exposed to Eylea at least once ([Table SVII.56](#)).

**Table SVII.56: Number of subjects with any cataract in the study eye (grouped term and included preferred terms) in the pivotal Phase III DME studies from baseline through Week 148 (SAF)**

MedDRA 19.1	Laser <sup>a</sup> n (%)	VTE 2Q4 <sup>b</sup> n (%)	VTE 2Q8 <sup>b</sup> n (%)	VTE total <sup>c</sup> n (%)
Number of subjects	287	291	287	821
Grouped term				
Cataract	67 (23.3)	88 (30.2)	67 (23.3)	188 (22.9)
Included preferred terms				
Cataract	38 (13.2)	56 (19.2)	44 (15.3)	121 (14.7)
Cataract cortical	12 (4.2)	9 (3.1)	12 (4.2)	27 (3.3)
Cataract nuclear	11 (3.8)	11 (3.8)	8 (2.8)	22 (2.7)

Cataract cortical	0	1 (0.3)	1 (0.3)	2 (0.2)
Cataract subcapsular	0	6 (2.1)	1 (0.3)	7 (0.9)

<sup>a</sup>: All subjects randomized to initial study eye treatment with active laser.

<sup>b</sup>: All subjects randomized to initial study eye treatment with Eylea (VTE 2Q4 or 2Q8).

<sup>c</sup>: All subjects from any treatment group (incl. laser group; N=243 exposed to additional/PRN treatment with Eylea) who received at least one active Eylea injection in the study eye; counting all AEs which started during or after the first Eylea injection in the study eye through Week 148.

Table Source: Integrated Analysis - EU-RMP Pool 1 (DME), Table 1.5.1/1

DME - Clinical Trial VIVID-EAST (52 weeks)

*All cataracts:*

Any cataracts in the study eye were reported in 10 patients (8.1%) in the laser group, 3 patients (2.4%) in the 2Q4 group, 2 patients (1.6%) in the 2Q8 group, and 6 patients (2.0%) in the Eylea total group (Table SVII.58). Thus, cataract cases occurred more frequently in the laser group than in the Eylea groups.

<sup>a</sup>: All subjects randomized to initial study eye treatment with active laser.

<sup>b</sup>: All subjects randomized to initial study eye treatment with Eylea (VTE 2Q4 or 2Q8).

<sup>c</sup>: All subjects from any treatment group (incl. laser group; N=45 exposed to Eylea) who received at least one active Eylea injection in the study eye; counting all AEs which started during or after the first Eylea injection in the study eye through Week 52.

Table Source: Integrated Analysis - EU-RMP Pool 1 (DME), Table 1.5.3/1.

*Injection-related (traumatic) cataracts:*

No cases of injection-related cataract in the study eye were reported in the VIVID-EAST study.

DME - Open-label Clinical Trial VIVID-JAPAN (52 weeks)

*All cataracts:*

In the open-label Phase III study VIVID-JAPAN, one patient (1.4% of the 72 subjects included in the SAF) experienced one treatment-emergent adverse event of cataract in the study eye through Week 52. This event was non-serious, but severe and non-resolved.

*Injection-related (traumatic) cataracts:*

No injection-related (traumatic cataracts) were reported in the open-label Phase III study VIVID-JAPAN.

Post-marketing Data

As of 15 SEP 2017, a total of 713 cases (including 786 events) with any cataract were reported.

Considering the sales figures and the estimated cumulative patient exposure in the post-marketing period until 30 SEP 2017, the reporting rate of "cataract" cases (N=713) was 0.04 cases per 1,000 sold vials (0.004%) and 0.31 cases per 1,000 patient years (0.031%), respectively.

AMD - Clinical Trial ALTAIR (52 weeks)

3 cases of cataracts were reported (2 occurring in the 2W adjustment group and 1 in the 4W adjustment group), none of the cases was serious. Outcome for these cases was reported as unknown.

CRVO Clinical Trials COPERNICUS and GALILEO (pooled data, 76/100 weeks)

*All cataracts:*

In 5 patients (4 in the Eylea 2Q4+PRN group and one in the sham group on treatment with Eylea) the reported cataract was regarded as serious (1.6% of patients in the Eylea total group; [Table SVII.67](#)).

**Table SVII.67: Number of subjects with serious cataract in the study eye (grouped term and included preferred terms) in the Phase III CRVO studies from baseline through Week 76/100 (SAF)**

<sup>a</sup>: All patients exposed to Eylea. All TEAEs occurring after first exposure are considered.

Table Source: Integrated Analysis - EU-RMP Pool 1 (CRVO), Table 1.3.1/3

*Injection-related (traumatic) cataracts:*

Only one patient in the CRVO studies (in the Eylea 2Q4+PRN group) experienced an injection-related cataract in the study eye (PT: Cataract). This event was considered serious and was not resolved.

**EYLEA<sup>®</sup>**  
(Aflibercept)  
EU Risk Management Plan

**Part II – Module SVII: Identified and Potential Risks**

BRVO Clinical Trial VIBRANT (52 weeks)

*All cataracts:*

A serious cataract was reported in one patient in the VTE 2 mg group (1.1% based on 91 patients, or 0.6% based on all 158 subjects exposed to Eylea). This serious event (PT: traumatic cataract) was regarded as injection-related (see description in text next paragraph).

*Injection-related (traumatic) cataracts:*

The only injection-related cataract reported by Week 52 (occurring in the Eylea group) was considered serious (severe intensity, resolved).

Myopic CNV Clinical Trial MYRROR (48 weeks)

*All cataracts:*

The only reported case of cataract (occurring in the Eylea 2 mg group) was non-serious; the outcome was "not recovered/not resolved".

*Injection-related (traumatic) cataracts:*

No injection-related (i.e., traumatic) cataracts were reported in MYRROR through Week 48.

DME - Pivotal Clinical Trials VIVID-DME and VISTA-DME (pooled data, 148 weeks)

*All cataracts:*

Serious cataracts in the study eye were reported in 4 patients in the laser group (1.4%), 11 patients in the Eylea 2Q4 group (3.8%), 9 patients in the Eylea 2Q8 group (3.1%) and 23 patients in the Eylea total group (2.8%; [Table SVII.69](#)).

**Table SVII.69: Number of subjects with any serious cataract in the study eye (grouped term and included preferred terms) in the pivotal Phase III DME studies from baseline through Week 148 (SAF)**

MedDRA 19.1	Laser <sup>a</sup> n (%)	VTE 2Q4 <sup>b</sup> n (%)	VTE 2Q8 <sup>b</sup> n (%)	VTE total <sup>c</sup> n (%)
Number of subjects	287	291	287	821

(Aflibercept)  
EU Risk Management Plan

**Part II – Module SVII: Identified and Potential Risks**

DME - Open-label Clinical Trial VIVID-JAPAN (52 weeks)

*All cataracts:*

The only reported event of cataract was non-serious, severe, and not resolved.

*Injection-related (traumatic) cataracts:*

No injection-related cataracts were reported in VIVID-JAPAN.

Post-marketing Data

Most of the 786 reported cataract events were serious (651 events), while 135 events were non-serious (see previous post-marketing table on cataract events).

Reported outcomes were "recovered/resolved" in 159 events, "recovering/resolving" in 95 events, "recovered/resolved with sequelae" in 2 events, and "not recovered/not resolved" in 165 events (missing or unknown outcomes in the remaining 365 events).

**Severity and nature of risk**

AMD - Pivotal Clinical Trials VIEW 1 and VIEW 2 (pooled data, 96 weeks)

*All cataracts:*

Similar to the incidence of serious cataracts, "severe" cataracts were reported in one patient (0.2%) on treatment with ranibizumab and 14 patients (0.8%) on treatment with Eylea (Table SVII.74). Thus, most of the events in either treatment group were mild or moderate.

**Table SVII.74: Number of subjects with cataract in the study eye by maximum severity in randomized Phase III wet AMD studies from baseline through Week 96 (Pool 1, SAF)**

---

DME - Open-label Clinical Trial VIVID-JAPAN (52 weeks)

*All cataracts:*

The only reported cataract case in VIVID-JAPAN was non-serious, severe, and non-resolved.

*Injection-related cataracts:*

No injection-related cataracts were reported in VIVID-JAPAN.

Post-marketing Data

Event severity is not routinely recorded on the post-marketing case report forms.

**Background incidence/prevalence**

Historically, traumatic cataract (TC) has been reported in patients receiving IVT injections, but limited information is available about cataract development or progression after intravitreal injection of VEGF inhibitors. In addition, due to differences in the way cataract and/or “traumatic cataract” have been defined or reported in such studies, the direct comparison of some reported rates could be difficult. Special attention should be given to the type of cataract the reported rates represent.

Several studies involving intravitreal injection (including ranibizumab, pegaptanib sodium, and triamcinolone acetonide) reported no findings of traumatic cataract (132), (219), (220), (221), (222).

Still, a limited number of reports revealed of low frequency of traumatic cataract associated with intravitreal injections of bevacizumab, ranibizumab, or triamcinolone (167), (218), (217), (223), (214), (224). Holz et al. specified 1 TC out of 513 patients (0.2%), Sorensen and Kemp reported one TC out of 647 eyes, and Jonas et al. reported that three eyes out of 5,403 injections (two in bevacizumab and one in triamcinolone acetonide) showed “progressive cataract” in a case series (218), (224), (217). The VISION study reported 5 TC events in 892 subjects (0.07%/injection) exposed to pegaptanib (167).

AMD:

In two double-blind placebo-controlled Pegaptanib trials involving 1208 patients, about 1% of patients developed cataract (225).

CRVO:

Several cohort and randomized studies on CRVO patients treated with different modalities reported information on traumatic cataract as an event to be noted:

A multicenter randomized, sham injection-controlled trial to assess the efficacy and safety of intraocular injections of 0.3 mg or 0.5 mg ranibizumab in patients with macular edema after CRVO. A total of 392 patients participated. At the end of 6 months the numbers of cataract cases were: 0/129 for sham, 2/132 (1.6%) for the 0.3 mg treatment group and 2/129 (1.6%) for the 0.5 mg group (171). At the end of 12 months follow-up of this study there were 7/131 cases (5.3%) of cataract in the sham group, 6/134 (4.5%) in the 0.3 mg group, and 8/130 (6.2%) in the 0.5 mg group (172).

**EYLEA<sup>®</sup>**  
(Aflibercept)  
EU Risk Management Plan

**Part II – Module SVII: Identified and Potential Risks**

---

**BRVO:**

A prospective, randomized, dose-finding study was performed to assess the efficacy and safety of IVT pegaptanib sodium for macular edema secondary to BRVO. Twenty subjects from three clinical practices in the United States with BRVO of more than 1 month and fewer than 6 months' duration were randomized 3:1 to IVT injections of pegaptanib 0.3 or 1 mg at Baseline and at weeks 6 and 12 with subsequent injections at 6-week intervals at investigator discretion until week 48. No cases of traumatic cataract were observed (222).

No other traumatic cataract events have been mentioned in the BRVO studies that have been reviewed.

**Myopic CNV:**

No data were identified.

**DME:**

A Korean study compared the efficacy of posterior sub-Tenon's capsule triamcinolone acetonide injection combined with modified grid macular photocoagulation (PSTI + MP) with intravitreal triamcinolone acetonide (IVTA) injection in the treatment of diffuse diabetic macular edema (DME). Forty eyes of 33 patients with diffuse DME were randomly allocated to either treatment. Examinations were carried out at baseline and also at 1 month, 3 months and 6 months after treatment.

The average increases in cataract grading (based on the Lens Opacities Classification System III (LOCS III), compared to baseline values, were  $0.62 \pm 0.81$  (mean  $\pm$  SD) in the PSTI + MP group and  $1.54 \pm 1.33$  in the IVTA group; the latter being significantly higher than the former ( $p = 0.043$ , Student's t-test). Significant cataract progression that necessitated cataract surgery was noted in 1 of 13 (7.7%) phakic eyes in the IVTA group, but in none of the eyes treated with posterior sub-Tenon injections (198).

In a Phase III controlled study, 197 patients with diabetic macular edema were randomized to receive a fluocinolone 0.5mg implant, or standard of care (macular grid laser/observation). Among phakic patients, cataract developed in 43.1% of patients treated with the fluocinolone implant and in 7.3% of patients treated with standard of care based on 34-week data. Patients in this trial will be followed for an additional 2.5 years (197).

The randomized trial of the Diabetic Retinopathy Clinical Research Group evaluated Ranibizumab vs. triamcinolone for treatment of DME. The two year cumulative cataract surgery events in the triamcinolone + prompt laser group was considerably higher (59%) than the rates for the sham + prompt laser group or the ranibizumab groups (14% and 14%, respectively;  $P < 0.001$  for both comparisons) (226).

**Impact on individual patient**

Development of cataract may impair vision and thus may require cataract surgery in order to remove the lens opacification.

**Risk factors and risk groups**

Cataract is a known adverse drug reaction on treatment with IVT corticosteroids.

**EYLEA<sup>®</sup>**  
(Aflibercept)  
EU Risk Management Plan

**Part II – Module SVII: Identified and Potential Risks**

---

### **Preventability**

By correct IVT procedure and a correct angle of the needle while injecting a cataract could be prevented. This is common knowledge of injecting physicians.

### **Impact on risk-benefit balance of the product**

An educational program is performed as an additional risk minimization measure to raise patients' and physicians' awareness on identified and potential risks. The effectiveness of this program was verified with a post authorization safety study (SN 16526).

This important identified risk does not have an impact on the positive risk-benefit balance of Eylea.

### **Public health impact:**

Patients experiencing (traumatic) cataract may require cataract surgery.

### **SVII.3.1.6 Potential risk: Medication errors**

#### **Potential mechanism**

Not applicable.

#### **Evidence source(s) and strength of evidence**

Main reason for considering medication error as an important potential risk:

Although Eylea is provided in a pre-filled syringe, there is an excess volume which exceeds the recommended net dose of 2 mg Eylea per injection. Thus, injecting the entire volume of the pre-filled syringe would result in overdose. However, this numerical overdose is limited, and the drug will be administered only by qualified physicians (not by patients), and this reduces the risk of inappropriate dosing and administration as well. No clinically meaningful events of overdose have been reported so far (neither in clinical trials nor in usual care). Nevertheless, it was decided to consider "medication error" a potential risk of treatment, which is, however, completely avoidable by proper adherence to the dosing recommendations.

Evidence sources: refer to the [linked subsection](#).

MedDRA search terms (version 19.1 for clinical studies and version 20.0 for PM data):

Search is performed using the MedDRA SMQ: "Medication errors".

### **Characterization of the risk**

#### **Frequency**

AMD - Pivotal Clinical Trials VIEW 1 and VIEW 2 (pooled data, 96 weeks)

Through the 2-year period in the Phase III AMD studies, 10 cases of overdose in 36,203 injections (including 9,810 ranibizumab injections) have been reported. Two overdose reports were with ranibizumab (0.02% of injections) and 8 with Eylea (0.03% of injections). In one case, 10-fold the dose and volume of the study drug was administered. Three of the patients experienced a transient increase of IOP. The IOP increase was probably associated with the larger volume administered. In the other cases, no AEs occurred. All patients recovered

**EYLEA<sup>®</sup>**  
(Aflibercept)  
EU Risk Management Plan

**Part II – Module SVII: Identified and Potential Risks**

without sequelae. (Note: not all of above occurrences necessarily reported PTs pertaining to medication error).

PTs pertaining to medication error occurred in 4 patients (0.7%) who were treated with ranibizumab, compared to 5 patients (0.3%) in the combined group of patients on treatment with Eylea (Table SVII.84).

**Table SVII.84: Number of subjects with medication errors (grouped term and included preferred terms) in randomized Phase III wet AMD studies from baseline through Week 96 (SAF)**

MedDRA 19.1	Ranibizumab		Eylea		Total n (%)
	Q4 n (%)	2 mg Q4 n (%)	0.5 mg Q4 n (%)	2 mg Q8 n (%)

---

concomitantly administered tramadol (for restless leg syndrome) in a 72-year-old Caucasian male (Subject No. ████████ in study VGFT-OD-1009 [VISTA-DME]).

DME - Clinical Trial VIVID-EAST (52 weeks)

No cases of medication error were reported in VIVID-EAST.

DME - Open-label Clinical Trial VIVID-JAPAN (52 weeks)

No cases of medication error were reported in VIVID-JAPAN.

Post-Marketing Data

By 15 SEP 2017, a total of 3,245 cases of medication error were reported with 3,577 events. The 5 most frequently reported preferred term events were “inappropriate schedule of drug administration” (1,476 events), “drug dose omission” (583 events), “product use issue” (523 events), “multiple use of single-use product” (263 events), and “product use in unapproved indication” (172 events).

Vial/dose fractioning (coded to PT “multiple use of single-use product”) is a common practice in some countries, and it might be supported by some health insurances. This PT was reported in 263 cases (with 263 events) and more than half of these cases (138 cases) were invalid, while 125 cases were valid. Most of the valid cases were associated with intraocular inflammations/infections which is an established and labeled ADR of the Eylea injection. For these cases it remains unknown whether the procedure of vial splitting contributed to the development of an intraocular infection. Overall, no increase in reporting rates for reported intraocular inflammations/infections was observed over the years worldwide, and to date, the reported number of cases with vial fractioning is considered low.

In view of the large number of vials sold by 15 SEP 2017 (almost 16 million), there is no indication that medication errors might be a relevant issue of treatment with Eylea in routine care. Numerically, the reporting rate of cases with medication error (N=3,245) was 0.20 cases per 1,000 sold vials (0.020%) and 1.40 cases per 1,000 patient years of exposure (0.140%), respectively.

\*: MedDRA Version 20.0. Figures are event-based, i.e., more than one preferred term event per reported case is possible. Included are both medically confirmed and non-medically confirmed events.

### Seriousness/outcomes

#### AMD - Pivotal Clinical Trials VIEW 1 and VIEW 2 (pooled data, 96 weeks)

All cases of medication error in the Eylea groups were regarded as non-serious, and all events were completely resolved. In the ranibizumab group, one case (incorrect dose administered; reason for seriousness not reported) was regarded as serious; all events (including the SAE) were completely resolved.

#### AMD - VIEW 1 long-term extension study

No cases of medication error were reported in the VIEW 1 extension study period.

#### AMD - Clinical Trial SIGHT (52 weeks)

No cases of medication error were reported during the course of the SIGHT study.

#### AMD - Clinical Trial ALTAIR (52 weeks)

No cases of medication error were reported during the course of the ALTAIR study.

#### CRVO Clinical Trials COPERNICUS and GALILEO (pooled data, 76/100 weeks)

No cases of medication error were reported in the Phase III CRVO studies.

#### BRVO Clinical Trial VIBRANT (52 weeks)

No cases of medication error were reported in the Phase III BRVO study.

#### Myopic CNV Clinical Trial MYRROR (48 weeks)

No cases of medication error were reported in the MYRROR study through Week 48.

#### DME - Pivotal Clinical Trials VIVID-DME and VISTA-DME (pooled data, 148 weeks)

The only reported case of medication error through Week 148 (PT: "accidental overdose") was not associated with Eylea treatment, but with an unintentional overdose of concomitantly administered tramadol. This event was serious and severe; the patient recovered.

#### DME - Clinical Trial VIVID-EAST (52 weeks)

No cases of medication error were reported in VIVID-EAST.

#### DME - Open-label Clinical Trial VIVID-JAPAN (52 weeks)

No cases of medication error were reported in VIVID-JAPAN.

**EYLEA<sup>®</sup>**  
(Aflibercept)  
EU Risk Management Plan

**Part II – Module SVII: Identified and Potential Risks**

Post-marketing Data

A few of the reported medication error cases were considered serious (49 cases [1.5% of all 3,245 cases] with 52 events [1.5% of all 3,577 events]; see previous post-marketing table).

For most of the 3,577 cases, the event outcome was unknown or not reported (3,283 events). Specified event outcomes were “recovered/resolved” (159 events), “recovering/resolving” (21 events), “recovered/resolved with sequelae” (one event), and “not recovered/not resolved” (113 events).

**Severity and nature of risk**

AMD - Pivotal Clinical Trials VIEW 1 and VIEW 2 (pooled data, 96 weeks)

Medication error events occurring on treatment with Eylea were of moderate intensity in 3 cases (missing severity in the remaining 2 cases; [Table SVII.86](#)). In the ranibizumab group, the serious adverse event (incorrect dose administered) was of severe intensity; one case was moderate, and the remaining 2 cases were mild.

**Table SVII.86: Number of subjects with medication error by maximum severity in randomized Phase III wet AMD studies from baseline through Week 96 (SAF)**

MedDRA 19.1	Ranibizumab		Eylea		Total n (%)
	Q4 n (%)	2 mg Q4 n (%)	0.5 mg Q4 n (%)	2 mg Q8 n (%)	
Number of subjects	595	613	601	610	1,824
Grouped term					
Medication error and misuse	4 (0.7)	2 (0.3)	1 (0.2)	2 (0.3)	5 (0.3)
Maximum severity					
Missing	0	1 (0.2)	0	1 (0.2)	2 (0.1)
Mild	2 (0.3)	0	0	0	0
Moderate	1 (0.2)	1 (0.2)	1 (0.2)	1 (0.2)	3 (0.2)
Severe	1 (0.2)	0	0	0	0

Q4 = every 4 weeks, Q8 = every 8 weeks

Note: At each level of subject summarization (Safety topic/PT), a subject is classified according to the maximum intensity, if the subject reported one or more events. At each level of subject summarization, a subject is counted only once.

No cases of medication error were reported in VIVID-EAST.

DME - Open-label Clinical Trial VIVID-JAPAN (52 weeks)

No cases of medication error were reported in VIVID-JAPAN.

Post-marketing Data

Event severity is not routinely recorded on the post-marketing case report forms.

**Background incidence/prevalence**

Not applicable.

**Impact on individual patient**

There is no life-threatening potential when Eylea is administered by an incorrect route.

**Risk factors and risk groups**

Not applicable.

**Preventability**

Instructions on the correct drug preparation and administration will be given in the SmPC and the educational program in order to minimize the risk of accidental medication errors.

The use of pre-filled syringes (PFS) limits any potential overdose to the volume in the syringe, so there can be no 10-fold overdose with the PFS.

**Impact on risk-benefit balance of the product**

An educational program is performed as an additional risk minimization measure to raise patients' and physicians' awareness on identified and potential risks. The effectiveness of this program was verified with a post authorization safety study (SN 16526).

This important potential risk does not have an impact on the positive risk-benefit balance of Eylea.

**Public health impact**

There is no life-threatening potential when Eylea is administered by an incorrect route.

**EYLEA<sup>®</sup>**  
(Aflibercept)  
EU Risk Management Plan

**Part II – Module SVII: Identified and Potential Risks**

### SVII.3.1.7 Potential risk: Off-label use and misuse

#### Potential mechanism

Not applicable.

#### Evidence of source(s) and strength of evidence

Main reason for considering off-label use and misuse as an important potential risk:

As with other drugs, Eylea might be intentionally used other than recommended, or in clinical conditions outside the approved indications (so-called off-label use). Since the clinical experience with Eylea in such off-label use will be limited (in particular in terms of efficacy and safety), any case of off-label use will be considered a potential risk. Since Eylea has no dependence potential, the risk of misuse is regarded as very low.

Evidence sources: refer to the [linked subsection](#).

MedDRA search terms (version 19.1 for clinical studies and version 20.0 for PM data):

Preferred term included in search: Off-label use, intentional device misuse, intentional overdose, and intentional product misuse.

#### Characterization of the risk

##### Frequency:

Phase III-IV clinical studies (AMD, CRVO, BRVO, myopic CNV, and DME)

There were no reports of off-label use or misuse in the herein reported Phase III-IV trials in wet AMD, CRVO, BRVO, myopic CNV, and DME.

##### Post-Marketing Data

Cases of off-label use were identified based on a concept that considered events of intentional drug use outside of the authorized product information in therapeutic intention as reported by HCP (or HCP involved). Preferred terms included in that safety topic were “off label use”, “intentional device misuse”, “intentional overdose”, and “intentional product misuse”.

By 15-SEP-2017, there were 1,846 recorded cases (including 1,925 events) of off-label use and misuse ([Table SVII.87](#)). Considering the sales figures and the estimated cumulative patient exposure in the post-marketing period until 30 SEP 2017, the reporting rate of off-label cases (N=1,846) was 0.12 cases per 1,000 sold vials (0.012%) and 0.80 cases per 1,000 patient years (0.080%), respectively.

**Table SVII.87: Number of post-marketing events "off-label use and misuse" by 15 SEP 2017**

<b>Group: Off-label use and misuse</b>	<b>1,846 cases</b>		
<b>Grouped preferred terms *:</b>	<b>Non-serious</b>	<b>Serious</b>	<b>All</b>
Off label use	1,904	10	1,914
Intentional product misuse	11	0	11
<b>Total number of events</b>	<b>1,915</b>	<b>10</b>	<b>1,925</b>

**EYLEA®**  
(Aflibercept)  
EU Risk Management Plan

**Part II – Module SVII: Identified and Potential Risks**

---

A review of these cases suggested that many cases of off-label use and misuse occurred within a labelled indication and were solely associated with deviations from the labeled treatment schedule or were used for indications that were not yet approved locally at the time of their use (but were approved elsewhere). For a high-level check of the treatment indication, the data base field “product indication preferred term” was screened.

Conditions associated with AMD (AMD not further specified) were reported as indication in 586 cases, explicitly wet AMD in 546 cases, any diabetic conditions in 624 cases, and retinal vein occlusion in 32 cases (multiple specifications per patient were possible). CNV not associated with one of these 3 conditions was reported in 83 cases; in 217 cases, no indication at all was provided.

The cases of off-label use and misuse were specifically screened for off-label treatment indications associated with glaucoma, diabetic retinopathy, polypoidal choroidal vasculopathy (PCV), pigment epithelium detachment (PED), and retinopathy of prematurity (ROP)

The indication "glaucoma" was reported in 9 cases; in 4 cases the pathogenesis as “neovascular/neovascularization” glaucoma was explicitly mentioned in the corresponding product reported indication terms:

- [REDACTED]: Reported indication: Neovascular glaucoma.
- [REDACTED]: Reported indication: Glaucoma prevention.
- [REDACTED]: Reported indication: Glaucoma.
- [REDACTED]: Reported indication: Glaucoma.
- [REDACTED]: Reported indication: Glaucoma.
- [REDACTED]: Reported indication: Glaucoma.
- [REDACTED]: Reported indication: Neovascular glaucoma (rubeosis iridis).
- [REDACTED]: Reported indication: Neovascular glaucoma at status after CRVO.
- [REDACTED]: Reported indication: Iris neovascularization glaucoma.

No other adverse events (including those potentially indicating acute issues with high IOP) were reported in these 9 cases (apart from the events “visual impairment” and “drug ineffective” in case No. [REDACTED]).

The indication "diabetic retinopathy" (coded to PT “diabetic retinopathy”) was reported in 27 cases.

The indication "PCV" (coded to PT “Polypoidal choroidal vasculopathy”) was reported in 7 cases (case Nos. [REDACTED]).

The indication "PED" (coded to PTs: Detachment of [macular] retinal pigment epithelium) was reported in 6 cases (case Nos. [REDACTED]).

The indication "ROP" (coded to PT: “Retinopathy of prematurity”) was reported in 8 cases (case Nos. [REDACTED] [no age provided], [REDACTED] [age: 1 month], [REDACTED] [age: 2 months], [REDACTED] [no age provided], [REDACTED] [age: <1 month], [REDACTED] [no age provided], [REDACTED] [no age provided], and [REDACTED] [no age provided]).

**EYLEA<sup>®</sup>**  
(Aflibercept)  
EU Risk Management Plan

**Part II – Module SVII: Identified and Potential Risks**

---

Administration of Eylea in pediatric patients <18 years was reported in 12 cases:

- [REDACTED]: Age: 13 years. Product indication (coded to PT): Retinal scar.
- [REDACTED]: Age: One month. Product indication (coded to PT): Retinopathy of prematurity.
- [REDACTED]: Age: 9 years. Product indication (coded to PT): Choroidal neovascularisation
- [REDACTED]: Age: 11 years. Product indication (coded to PT): Choroidal neovascularisation
- [REDACTED]: Age: 16 years. Product indication (coded to PT): Retinal neovascularisation.
- [REDACTED]: Age: 2 months. Product indication (coded to PT): Retinopathy of prematurity.
- [REDACTED]: Age: 11 years: Product indication (coded to PT): Retinal neovascularisation.
- [REDACTED]: Age: 14 years. Product indication (coded to PT): Exudative retinopathy.
- [REDACTED]: Age: <1 month. Product indication (coded to PT): Not provided.
- [REDACTED]: Age: 14 years. Product indication (coded to PT): Macular hole.
- [REDACTED]: Age: <1 month. Product indication (coded to PT): Retinopathy of prematurity.
- [REDACTED]: Age: <1 month. Product indication (coded to PT): Choroidal neovascularisation, iris neovascularisation.

None of these 12 cases was associated with adverse events.

### **Seriousness/outcomes**

#### Phase III-IV clinical studies (AMD, CRVO, BRVO, myopic CNV, and DME)

Not applicable, since no related events were reported.

#### Post-marketing Data

In 10 cases the off-label use was regarded as serious. These included the following events (events are as reported term):

- [REDACTED]: Off-label use event as reported term: “Receiving treatment with EYLEA therapy for blood behind the right eye (OD)”. Product indication (coded to PT): “Eye haemorrhage”. Reason for seriousness: Medically significant. Outcome: Unknown.
- [REDACTED]: Off-label use event as reported term: “Eylia was used for retinopathy of prematurity”. Product indication (coded to PT): “Retinopathy of prematurity”. Reason for seriousness: Hospitalization. Outcome: Not reported.
- [REDACTED]: Off-label use event as reported term: “Eylea was used without loading phases (off label use)”. Product indication (coded to PT): “neovascular AMD”. Reason for seriousness: Disability. Outcome: Not reported.

**EYLEA<sup>®</sup>**  
(Aflibercept)  
EU Risk Management Plan

**Part II – Module SVII: Identified and Potential Risks**

---

- [REDACTED]: Off-label use event as reported term: “EYLEA indication for use reported as "anemia, unspecified"”. Product indication (coded to PT): “Anaemia”. Reason for seriousness: Hospitalized / Medically Significant. Outcome: Not recovered/not resolved.
- [REDACTED]: Off-label use event as reported term: “Eylea in CNV of unknown origin (possibly retinopathia centralis serosa) (off-label)”. Product indication (coded to PT): “CNV, chorioretinopathy”. Reason for seriousness: Medically significant. Outcome: Not reported.
- [REDACTED]: Off-label use event as reported term: “Used Eylea for stroke in left eye causing vision problems”. Product indication (coded to PT): “Visual impairment”. Reason for seriousness: Medically significant. Outcome: Unknown.
- [REDACTED]: Off-label use event as reported term: “Indication for Eylea; retinal macroaneurysm and retinal hemorrhage”. Product indication (coded to PT): “Retinal haemorrhage” and “retinal aneurysm”. Reason for seriousness: Medically significant. Outcome: Unknown.
- [REDACTED]: Off-label use event as reported term: “Indication for use iridoschisis”. Product indication (coded to PT): “Iridoschisis”. Reason for seriousness: Medically significant. Outcome: Unknown.
- [REDACTED]: Off-label use event as reported term: “Indication, malignant neoplasm of prostate”. Product indication (coded to PT): “Prostate cancer”. Reason for seriousness: Medically significant. Outcome: Unknown.
- [REDACTED]: Off-label use event as reported term: “Eylea used for retina separation in the right eye, left “eye is bad” (off label use)”. Product indication (coded to PT): “Retinoschisis” and “eye disorder”. Reason for seriousness: Disability/ medically significant. Outcome: Unknown.

Generally, an outcome for the 1,925 events of off-label use and misuse was provided only for 113 events: "recovered/resolved" in 19 events, "recovering/resolving" in 15 events, and "not recovered/not resolved" in 79 events; the outcomes for the remaining 1,812 events were unknown or missing.

### **Severity and nature of risk**

Phase III-IV clinical studies (AMD, CRVO, BRVO, myopic CNV, and DME)

Not applicable, since no related events were reported.

Post-marketing Data

Event severity is not routinely recorded on the post-marketing case report forms.

### **Background incidence/prevalence:**

Not applicable.

### **Impact on individual patient**

Not applicable.

### **Risk factors and risk groups**

Not applicable.

**EYLEA<sup>®</sup>**  
(Aflibercept)  
EU Risk Management Plan

**Part II – Module SVII: Identified and Potential Risks**

---

### **Preventability**

Eylea is being studied in many conditions for which off-label use might be considered.

Off-label ophthalmic use has been reported with currently marketed VEGF inhibitors, e.g., for bevacizumab for the treatment of wet AMD (227) or DME (228), (229). Off-label use of ranibizumab has been reported for ophthalmic diseases other than wet AMD such as DME (230) or retinal vein occlusion (231) before market authorization was granted in the respective indications. There are also reports on off-label use of bevacizumab and ranibizumab in rarer diseases such as myopic CNV (in countries where myopic CNV is not labelled), or retinopathy of prematurity (230), reviewed in Andreoli and Miller (232). In general, as for the majority of possible indications for anti-VEGF therapy approved medications are available, the potential for off-label use is considered minimal. Additionally, non-approved indications are currently being investigated in various studies to establish safety and efficacy in these therapeutic areas.

Most neovascular and VEGF dependent retina diseases including particularly AMD are diseases of the adult. Therefore, the potential for off-label use in the pediatric population is expected to be very limited due to the nature of pediatric ophthalmic diseases. However, there might be exceptions to be considered, as reviewed in Andreoli and Miller (232). In some rare cases, diabetic retinopathy may occur in adolescents. Some ophthalmologists tend to use off-label anti-VEGF drugs in this disease instead of the approved therapy. Myopic CNV, CRVO, and BRVO may also very rarely occur in adolescents and may be treated off-label with any IVT anti-VEGF drug, including Eylea. Eylea may be also used to treat some cases of retinopathy of prematurity (233). The number of such cases is considered very low and their care is provided by pediatric ophthalmologists who are tertiary care based and experienced in the care of these infants.

Intentional misuse, as such, is difficult to prevent because of the user's deliberate decision to deviate from the provided instructions. However, there is no known dependence potential of Eylea.

### **Impact of risk-benefit balance of the product**

An educational program is performed as an additional risk minimization measure to raise patients' and physicians' awareness on identified and potential risks. The effectiveness of this program was verified with a post authorization safety study (SN 16526).

This important potential risk does not have an impact on the positive risk-benefit balance of Eylea.

### **Public health impact**

Not applicable.

### **SVII.3.1.8 Potential risk: Embryo-fetotoxicity**

#### **Potential mechanism**

An embryo-fetal toxicity study was performed in the rabbit with IV dosing of aflibercept at doses which provided systemic exposures over 670-fold higher than that observed with IVT dosing using the clinical dose of 2 mg. The study identified dose-related increases in fetal resorptions, pregnancy disruptions and numerous fetal (external, visceral and skeletal)

**EYLEA<sup>®</sup>**  
(Aflibercept)  
EU Risk Management Plan

**Part II – Module SVII: Identified and Potential Risks**

---

malformations. These effects were thought to be due to the antiangiogenic effect of aflibercept. For more details see [Part II Module SII](#).

### **Evidence source(s) and strength of evidence**

#### Main reason for considering embryo-fetotoxicity as an important potential risk:

Testing of Eylea in animals was performed as a standard part of the development of Eylea. It was noted that Eylea given in extremely high doses to animals (by far exceeding the doses which would be given to humans) might have an adverse influence on prenatal development (i.e., during the embryonic or fetal development period; so-called embryo-fetotoxicity). Therefore, embryo-fetotoxicity is regarded as a potential risk of treatment with Eylea. However, Eylea is injected locally and at a dose that is distinctively lower than the exposure in animals under which the critical events were observed. So far, there is no relevant indication that treatment with Eylea might be associated with embryo-fetotoxicity.

Evidence sources: refer to the [linked subsection](#).

MedDRA search terms (version 19.1 for clinical studies and version 20.0 for PM data):

SMQ search:

- Congenital, familial and genetic disorders,
- Termination of pregnancy and risk of abortion,
- Fetal disorders.

In addition, all cases associated with the PT “Pregnancy” are routinely checked in order to ensure appropriate and complete follow-up of any pregnancy.

### **Characterization of the risk**

#### **Frequency**

##### **Phase I-IV clinical studies**

Currently, there are 8 cases of pregnancy reported from clinical studies by 15 SEP 2017 (direct exposure or exposure through male partner):

1) Case no. [REDACTED] 43-year-old male; PTs: i) "syncope", ii) "drug exposure via father/no adverse event". This patient was treated in CRVO study 14130 (GALILEO) and actively exposed to Eylea. Eylea was discontinued on [REDACTED]. Follow-up for another adverse event (syncope) received in NOV 2011 revealed that the patient's partner had become pregnant (expected delivery date in JUL 2012). Further follow-up revealed that an abortion had been electively performed on an unknown date, since the subject and his partner did not want the pregnancy (see related case no. [REDACTED]).

2) Case no. [REDACTED]; 39-year-old female; PT: drug exposure via father/no adverse event. This case was entered as a result of the previous case report (this woman was the pregnant partner of the aforementioned GALILEO study patient). The patient had a history of one pregnancy and one induced abortion. No contraceptives or an intra-uterine device, but only a condom had been used. The patient was exposed to study drug (VEGF trap eye or sham) via her partner during her pregnancy which was confirmed by HCG test and an ultrasonography on [REDACTED]. No adverse event was reported. The patient performed an elective abortion

**EYLEA<sup>®</sup>**  
(Aflibercept)  
EU Risk Management Plan

**Part II – Module SVII: Identified and Potential Risks**

---

on an unknown date, since the subject and her partner did not want the pregnancy. No medical reason in the mother or in the fetus was reported (see related case no. [REDACTED]).

3) Case no. [REDACTED] 22-year-old female; PT: Pregnancy. This Russian patient was enrolled in study No. 15161 (VIVID-EAST). On [REDACTED] the patient started Eylea or sham laser, one time for 4 weeks at an unspecified dose for DME. The patient's previous contraception was condoms; she had not had previous pregnancies. On an unspecified date the patient experienced pregnancy. The patient's last menstrual period was on [REDACTED]. On [REDACTED], pregnancy was confirmed with HCG pregnancy test and ultrasonography. At 2 to 3 weeks, on [REDACTED], abortion was done due to the patient's decision. Action taken with aflibercept was not reported.

4) Case no. [REDACTED] This case number refers to a 36-year-old female who was treated in the USA in the VISTA-DME study (study patient no. [REDACTED]). The patient had a medical history of diabetes mellitus type I, stage IV kidney disease, hypertension, hyperthyroidism, hyperphosphatemia, and hypercholesterolemia. This patient became pregnant during the study treatment period (PT: Maternal exposure during pregnancy [non-serious; resolved]) and subsequently experienced preeclampsia (PT: Pre-eclampsia [serious; resolved]) requiring premature delivery of twins (PT: premature delivers [serious; resolved]). The patient had received 36 study treatments of masked VTE or laser to the study eye and 6 open-label study treatments to the fellow eye. Actually, the patient was randomized to treatment assignment with VTE 2Q8 (unmasked information) and exposed to study medication from [REDACTED] to [REDACTED] (last planned administration time point of study drug before the event)<sup>11</sup>. Study Visit 39 was on [REDACTED]. Her first positive pregnancy test occurred on [REDACTED]; pregnancy was confirmed on [REDACTED] (pregnancy duration 5-6 weeks; pregnant with twins). Afterwards, the study site contacted the patient on a monthly basis from [REDACTED], when the patient was found to be 23 weeks pregnant with no previous complications during her pregnancy.

On [REDACTED], the patient was admitted to the hospital due to high blood pressure and possible preeclampsia. The patient's blood pressure was stabilized, and she was discharged from the hospital on [REDACTED]. On [REDACTED], the patient was re-admitted to the hospital due to elevated blood pressures at home with nausea, vomiting and shortness of breath. Upon admission, patient's shortness of breath worsened with IV fluids (given for treatment of dehydration) and a chest x-ray revealed developing pulmonary edema while echocardiogram results were normal. She was started on IV Lasix (furosemide). Due to non-reassuring fetal tracings and the inability to stabilize the patient's condition, an emergency Caesarean section was performed on the same day. The gestational age of the babies at the time of the delivery was 25-26 weeks (see Case No. [REDACTED] for female Baby A and Case No. [REDACTED] for male Baby B). After delivery, the patient was stable and transferred to the ICU. A chest x-ray revealed pulmonary edema. Progressive worsening of renal function had been seen during her pregnancy from baseline creatinine 2.6 to 3.7 [mg/dL]

---

<sup>11</sup> **The review of the patient data listings revealed the following exposure information:**

- Overall, The patient received 20 active Eylea injections in the study eye.
- On [REDACTED] (last administration date before the event), she received a sham injection in the study eye.
- The patient did not meet laser re-treatment criteria on [REDACTED], and did not receive laser.
- The patient received 2 ranibizumab and 6 Eylea injections in the fellow eye between start of study through [REDACTED]

**EYLEA<sup>®</sup>**  
(Aflibercept)  
EU Risk Management Plan

**Part II – Module SVII: Identified and Potential Risks**

---

and worsening nephrotic range proteinuria of close to 11 grams. The patient was relatively stable on 2 liters of oxygen with a persisting cough. Post-operatively, she experienced decompensated heart failure with anasarca and pulmonary edema in the setting of Stage IV-V kidney disease from her diabetes. IV Lasix was replaced with a Bumex (bumetanide) drip. On 03 JAN 2015, the patient's condition was stable, and she was discharged from the hospital. She is continuing to follow-up with her endocrinologist and nephrologist (time point of last report: [REDACTED]).

According to the investigator, the event of preeclampsia was severe in severity and not related to the study drug or study procedure. The alternative explanation for the event was reported as an underlying/concomitant illness, specifically the patient's medical history of high blood pressure and kidney disease. Consistently, the Sponsor considered the event of preeclampsia not related to the study drug or study procedure.

5) Case no. [REDACTED] This case number refers to female Baby A (PT: premature baby [serious]) of the aforementioned 36-year-old female (see Case no. [REDACTED]). Baby A was potentially exposed to VTE *in utero*. The mother had been hospitalized on [REDACTED] for an emergency Caesarean section on the same day due to the babies' heart rates decreasing and her high blood pressure and preeclampsia. Baby A was female with a gestational age of 25-26 weeks, weight 1 lb. 5 ounces, length 12 inches, and she was immediately transported to the neonatal intensive care unit (NICU). Diagnoses made upon NICU admission were feeding problems in newborn (<28 days), hyponatremia (<125 [mmol/L]), respiratory distress syndrome, apnea of prematurity, apnea (drug treated), chronic lung disease (CLD) at 28 days, patent ductus arteriosus (PDA), anemia birth (HCT <40%), jaundice due to prematurity, rule out sepsis, anemia of prematurity, germinal matrix bleed (grade 1), retinopathy of prematurity grade 1 or 2, and fractures of tibia/fibula on right. Besides numerous other measures, such as parenteral nutrition and ventilation, blood cell transfusions were received on [REDACTED] and 08 JAN 2015. A head ultrasound done on [REDACTED] revealed a right-sided grade 1 intracranial hemorrhage with no ventriculomegaly. Hemorrhage was stable on 03 JAN 2015 and continued resolving through [REDACTED]. On [REDACTED], an echocardiogram was performed. Both left atrium and left ventricle chamber size were enlarged. There was a patent foramen ovale with left to right flow and a large patent ductus arteriosus. Shunt flow was left to right. PDA was small to moderate with continuous left to right flow (35 mmHg) and no suggestion of PPHN by [REDACTED]. PDA continued to decrease and on [REDACTED] there was a small aortopulmonary collateral which was not significant. Baby A passed ALGO hearing screen bilaterally on [REDACTED]. An x-ray of the right lower extremity done on [REDACTED] showed essentially complete interval healing of previously described fractures of the distal tibia and fibula with no new fractures identified. Baby A was cared for in the NICU for a total of 128 days and was discharged to home on [REDACTED]. Since discharge, Baby A was home with mother doing well (time point of last report: [REDACTED]).

According to the investigator, the event of premature birth was severe in severity and not related to the study drug or study procedure. The alternative explanation for the event was reported as an underlying/concomitant illness, specifically the mother's medical history of high blood pressure and kidney disease. Accordingly, the Sponsor considered the event of premature birth not related to the study drug or study procedure, and most likely secondary to underlying/concomitant illness, specifically the mother's medical history.

6) Case no. [REDACTED] This case number refers to male Baby B (PT: premature baby [serious]) of the aforementioned 36-year-old female (see Case no. [REDACTED]). Baby B was

**EYLEA®**  
(Aflibercept)  
EU Risk Management Plan

**Part II – Module SVII: Identified and Potential Risks**

---

potentially exposed to VTE in utero. The mother had been hospitalized on [REDACTED] for an emergency Caesarean section on the same day due to the babies' heart rates decreasing and her high blood pressure and preeclampsia. Baby B was male with a gestational age of 25-26 weeks, weight 1 lb. 4 ounces, and length 11.5 inches, and he was immediately transported to the NICU. Diagnoses made upon NICU admission were hypocalcemia (<7.0, units and range not provided), hyponatremia (<125, units and range not provided), feeding problems in a newborn, inguinal hernia, respiratory distress syndrome, apnea of prematurity, drug treated apnea, pneumothorax on left, pulmonary interstitial emphysema, chronic lung disease (CLD) at 28 days, patent ductus arteriosus, jaundice due to prematurity, thrombocytopenia (platelets <100,000, units and range not provided), neutropenia (ANC <1000, units and range not provided), sepsis ruled out and sepsis suspected, retinopathy of prematurity (ROP) (grade 1 or 2), ROP (zone 2, stage 3), and extreme prematurity. Besides numerous other measures, such as parenteral nutrition, ventilation, and antibiotic treatment, Baby B received phototherapy for 4 days, red blood cell transfusions, and was treated with erythropoietin. Echocardiogram performed on [REDACTED] showed a patent foramen ovale with left to right flow and a large patent ductus arteriosus, shunt flow left to right. On [REDACTED], echocardiogram showed no patent ductus arteriosus. Flow was seen into the ampulla, but flow was not seen through the ductus into the pulmonary artery. No intracranial hemorrhage or ventriculomegaly was noted in the head ultrasound. Baby B received ibuprofen for treatment of patent ductus arteriosus, and hydrocortisone for hypotension. On [REDACTED], an ECG was done. Arrhythmia was noted previously. EEG was normal on unspecified date. On [REDACTED], hematocrit was 33.8%. On [REDACTED], laser therapy was performed for ROP grade 1 or 2. ROP regressed in both eyes (OU) following laser treatment. Baby B passed ALGO hearing screen bilaterally on [REDACTED]. On [REDACTED], head ultrasound continued to be normal. Like his sister, Baby B was cared for in the ICN for a total of 128 days and was discharged to home on [REDACTED]. Since discharge, Baby B was home with mother doing well (time point of last report: [REDACTED]). According to the investigator, the event of premature birth was severe in severity and not related to the study drug or study procedure. The alternative explanation for the event was reported as an underlying/concomitant illness, specifically the mother's medical history of high blood pressure and kidney disease. Accordingly, the Sponsor considered the event of premature birth not related to the study drug or study procedure, and most likely secondary to underlying/concomitant illness, specifically the mother's medical history.

7) Case no. [REDACTED]: This 23-year-old female was treated in the scope of an investigator sponsored study (ISS) in Great Britain (SN 17216 [CLARITY] - Clinical Efficacy and Mechanistic Evaluation of Aflibercept for Proliferative Diabetic Retinopathy; subject No. [REDACTED]). The last menstrual period was on [REDACTED]. Eylea therapy was started on [REDACTED]. Pregnancy was confirmed on [REDACTED], and Eylea was discontinued on [REDACTED]. Pregnancy was ongoing at the time of the report; no further information available.

8) Case no. [REDACTED]: This 27-year-old female with proliferative diabetic retinopathy was treated in the scope of an investigator sponsored study (ISS) in Great Britain (SN 17216). She received Eylea on [REDACTED]. The date of last menstrual period was on [REDACTED]; pregnancy was confirmed on [REDACTED]. Thus, one Eylea injection during pregnancy was administered. The patient had 2 previous pregnancies. The first one was medically terminated in 2007, during the 15th gestational week, due to the child's abnormal brain development. In the second pregnancy, patient

**EYLEA<sup>®</sup>**  
(Aflibercept)  
EU Risk Management Plan

**Part II – Module SVII: Identified and Potential Risks**

---

delivered a male healthy baby, at 38th gestational week (induced forceps) in 2013. The patient's current child was born on [REDACTED]; mother and baby were reported as doing well (see related child case no. [REDACTED]).

9) Case no. [REDACTED]: This is a report of “drug exposure via mother” in a neonate female, related to the aforementioned case no. [REDACTED]. The mother was enrolled in ISS no. 17216 (title: “clinical efficacy and mechanistic evaluation of aflibercept for proliferative diabetic retinopathy”). The female baby was exposed to study drug aflibercept during her mother's pregnancy (via transplacental). The baby was also exposed (via transplacental) to concomitant drugs used by her mother during pregnancy: Novorapid (insulin aspart), Lantus (insulin glargine), Sertraline (sertraline), Chloramphenicol (chloramphenicol), and Optive (optive). The last dose of study drug given prior to pregnancy; confirmation was received on [REDACTED]. Date of last menses was [REDACTED], and pregnancy was confirmed on [REDACTED], with urine test. The child was born on [REDACTED] at 35th gestational week, delivered via cesarean section (elective). No antenatal problems were observed. The female baby had a body weight of 2,900 g. She had neonatal jaundice and was submitted to phototherapy. She was kept nil by mouth until [REDACTED] as she had bilious aspirate. No other concerns occurred. Mother and baby were reported as doing well (see related case no. [REDACTED]); event outcome was “recovered”.

10) Case no. [REDACTED] This is a clinical study case report received from an investigator from GB on 13 JAN 2016, which refers to a 40-year-old female patient who was enrolled in an investigator sponsored study (CLARITY; patient No. [REDACTED]) and experienced pregnancy, cesarean section, and diabetic ketoacidosis. On [REDACTED], the patient started study drug for proliferative diabetic retinopathy. On an unspecified date the patient experienced pregnancy. On [REDACTED] patient experienced diabetic ketoacidosis; the outcome was recovered on [REDACTED]. On [REDACTED], patient was seen and diagnosed with fetal growth restriction/intrauterine growth restriction (requiring Cesarean section) and fetal sublingual cyst (reported as symptom). The seriousness was due to required inpatient hospitalization. The estimated fetal weight was 5<sup>th</sup> centile with small reduction in growth velocity. Severity was severe and patient required Cesarean section.

Follow-up showed the following additional information: The first dose of study drug before pregnancy confirmation was given on [REDACTED] (note that the patient was allocated to the laser treatment arm and did not receive Eylea). The antenatal problems were poor glycemic control, nephropathy with edema to knees and intra uterine growth retardation. Previous pregnancy history were spontaneous vaginal delivery with 5 children, one caesarean section with intrauterine death still birth with fetal distress, and one miscarriage (gestation of 12 weeks). The patient did not know she was pregnant until she was 18 weeks pregnant. Her first ultrasound was on [REDACTED] which confirmed pregnancy. Impression of fetal growth retardation was only made on the ultrasound scan on [REDACTED], not before that. Patient remained inpatient from [REDACTED] for course of (unspecified) steroids, but after ultrasound scan decision for caesarian section was made. Other diagnosis were type I diabetes, diabetic neuropathy, known smoker, impaired glycemic control with hospital admission for hypoglycemia and diabetic ketoacidosis. The date of delivery was [REDACTED] with gestation of 33 weeks with mode of delivery caesarean section. The male neonate was delivered (no birth weight was reported). Patient was inpatient 1 week post caesarean section with edema to lower abdomen and limbs and thrombocytosis. Ultrasound resulted in no intra-abdominal collection.

**EYLEA<sup>®</sup>**  
(Aflibercept)  
EU Risk Management Plan

**Part II – Module SVII: Identified and Potential Risks**

---

A child case was created under the following case number [REDACTED].

11) Case no. [REDACTED]: This is the child case associated with case no. [REDACTED]. On [REDACTED] the patient's mother started study drug, and she received the last dose of study drug on [REDACTED] (no active Eylea exposure). On [REDACTED], the patient experienced "fetal growth restriction/ intrauterine growth retardation" and "fetal sublingual cyst", and therefore the patient was hospitalized. The investigator reported that the patient's mother was seen at hospital and was diagnosed with fetal growth restriction. The estimated fetal weight was on the fifth centile with small reduction in growth velocity which needed a cesarean section. According to the investigator the event "fetal growth restriction/ intrauterine growth retardation" started on [REDACTED] and the event "fetal sublingual cyst" started on [REDACTED], but both events became serious (hospitalization) on [REDACTED]. The outcome of the 2 events was reported as not resolved. The investigator considered the events "fetal growth restriction/ intrauterine growth retardation" started on [REDACTED] and "fetal sublingual cyst" as severe in severity and not related to study drug. Follow-up information showed that the sublingual cyst (cyst size 12.1x12.2x13 mm) was diagnosed through ultrasound on [REDACTED]. The size of the cyst remained static. No further information was provided.

12) Case no. [REDACTED]: This is a clinical study case report from GB which refers to a female patient of unspecified age whose partner, an adult male patient of unspecified age, was involved in an ISS (SN 17216; CLARITY). The patient's partner became pregnant. No information given on patient's past drugs and concurrent conditions. The patient did not take any regular medication. The patient's historical condition included childhood asthma. Past pregnancy history included female baby delivered on [REDACTED] at 41st gestational week, with 3.8 kg at birth, mode of delivery: forceps. Postnatal problems included baby tachycardia for 48 hours (special care baby unit) resolved fully, no explained cause found. On [REDACTED], the patient (study participant) started study drug; the patient also received the study drug on [REDACTED]. On an unspecified date the patient's partner became pregnant. The start date of last menses was reported as [REDACTED]. The pregnancy was confirmed on [REDACTED] using a digital pregnancy test (done at home). Expected due date reported for MAY 2017.

13) Case no. [REDACTED]: This case was reported from an US study (VGFT-OD-1329: Treatment for Central-Involved Diabetic Macular Edema in Eyes with Very Good Visual Acuity) and refers to a female patient of unknown age who became pregnant during the study. The patient received first dose of Eylea on an unknown date. The most recent dose of Eylea prior to onset of event was administered on [REDACTED]. The total number of doses the patient received prior to the onset of the event was not provided. Study drug was discontinued as a result of the pregnancy. The patient became pregnant on an unknown date in the last week of SEP 2016. It was reported that the patient is due in JUN 2017 and her last required follow-up visit for the study (104 weeks) will be in SEP 2017. No additional details are currently provided.

### Post-Marketing Data

As of 15 SEP 2017, 12 pregnancy cases were reported in the in the post-marketing setting outside a clinical study setting:

1) Case No. [REDACTED]: 47-year-old female; PT: "Abortion missed". The patient's medical history included 8 pregnancies with 5 healthy children and 2 spontaneous abortions. No

**EYLEA<sup>®</sup>**  
(Aflibercept)  
EU Risk Management Plan

**Part II – Module SVII: Identified and Potential Risks**

---

information was given on patient's drug history and concurrent conditions. The current conception was spontaneous; the patient had consumed wine until Gestational Week (GW) 4. The date of last menstrual period was [REDACTED]. On [REDACTED], the patient received Eylea at an unknown dosage regimen for CRVO and another dose of Eylea (aflibercept) was received in MAY 2014 (i.e., GW 2+6 days and approximately GW 8+2days). Ultrasound examinations were normal until a missed abortion occurring in GW 8. Although the patient's history of 2 spontaneous abortions and her age are known risk factors and might alternatively explain the event, the company assessment considered that the causality between the reported event and Eylea cannot be completely excluded.

2) Case No. [REDACTED]: 33-year old female; reported PTs: “Off label use” (verbatim: Eylea in CNV of unknown origin [possibly retinopathia centralis] [off-label]), “detachment of retinal pigment epithelium“, and “exposure during breast feeding”. No information was given on patient's history and past drugs. Her CNV was possibly due to a retinopathia centralis serosa. On an unspecified date the patient started Eylea at an unspecified dose for CNV. It was unknown whether Eylea was used previously. On an unspecified date after two successful Eylea administrations, the patient developed detachment of RPE, and she received administrations after that event. It was also reported that the patient became pregnant on an unspecified date; the temporal relationship to drug administration was unclear. Further follow-up information (last reported on 09 APR 2016) revealed that Eylea was administered during the breastfeeding period, not during pregnancy. No further information was provided.

3) Case No. [REDACTED]: 28-year-old female; reported PT: “Maternal exposure during pregnancy”. The patient's past medical history included diabetes mellitus, stage 2 kidney disease, polycystic ovarian syndrome, hypertension, diabetic gastropathy, neuropathy, elevated liver function tests diagnosed as hepatitis, and panic attacks. Concomitant medications included Novolog, labetalol, Xanax (discontinued in JAN 2016), unspecified cholesterol medication (discontinued in January 2016), and vitamin D (discontinued in January 2016). Treatment with Eylea for macular edema and diabetic retinopathy, intravitreal injection monthly (unspecified dose), was initiated in AUG or SEP 2015. The last dose was administered in JAN 2016. In JAN 2016, the patient determined she was pregnant and Eylea was discontinued. The delivery date was reported as [REDACTED]. Trimester of exposure began in first trimester (calculated from due date). The patient was seeing a high risk obstetric-gynecologist every 2 weeks. At the time of initial reporting, all ultrasounds were normal and no amniocentesis was performed. The outcome of the pregnancy is currently unknown (last report on [REDACTED]).

4) Case No. [REDACTED]: 41-year-old female; reported PTs: “Maternal exposure before pregnancy”, “abortion spontaneous”, and “product use issue” (verbatim: received the second Eylea injection with more than one month of interval). The patient had 3 pregnancies, one full-term birth and 2 stillbirths. There were no problems in the previous completed pregnancy. No information was given on patient's history, past drugs, concomitant medication and concurrent conditions. It was unknown whether Eylea was used previously. The patient received a total of 2 Eylea injections for DME, at 0.05 mL IVT, on [REDACTED]. The patient got pregnant 3 weeks after the last Eylea injection, and the ophthalmologist stopped injecting Eylea after the knowledge of the pregnancy. Pregnancy was confirmed by HCG (pregnancy test) and ultrasonography. The expected date of delivery was reported as [REDACTED]. However, a spontaneous abortion occurred at 10 weeks of gestational age, and the child had a stillbirth of unknown origin on [REDACTED]. Patient had

**EYLEA®**  
(Aflibercept)  
EU Risk Management Plan

**Part II – Module SVII: Identified and Potential Risks**

---

no problems in previous pregnancy. This event was not related to Eylea according to physician because patient already had several miscarriages before. Despite follow-up attempts, no further information was received.

5) Case No. [REDACTED]: female of unknown age; reported PTs: “Prolonged pregnancy” and “off label use” (verbatim: receiving Eylea injections for retinal artery occlusion/thrombosis). The patient's medical history and concomitant medications were not provided. Treatment with Eylea for retinal artery occlusion/thrombosis was initiated on an unknown date (dosing and frequency not specified). On an unknown date, the patient experienced prolonged pregnancy (verbatim event: “was 10 months pregnant”). The event outcome and action taken with Eylea were unknown. At the time of the current report ([REDACTED]), no further information was available.

6) Case No. [REDACTED]: 28-year-old female; reported PT: “Maternal exposure during pregnancy”. The patient's medical history included 2 previous pregnancies. The patient was diagnosed with RVO in the right eye following her second pregnancy. Concomitant medication was not reported. Treatment with Eylea was initiated on an unknown date and administered every 6 weeks (dosing not reported). The patient had received an unknown number of injections. On an unknown date, the patient became pregnant, and at the time of this most recent report ([REDACTED]) she was in the first trimester. No additional information was provided.

7) Case No. [REDACTED] 26-year-old female; reported PTs: “Diabetes mellitus inadequate control” (verbatim: rebalancing diabetes), “abortion spontaneous” (verbatim: stopped pregnancy [miscarriage]), and “maternal exposure during pregnancy”. This patient started unilateral treatment with Eylea 2 mg q8w on [REDACTED], the dose was changed to injection in both eyes, and further treatments at the same dose were continued on [REDACTED]. The patient's last menstrual period was on [REDACTED] and estimated date of delivery was [REDACTED]. Pregnancy was confirmed by  $\beta$ -HCG test on [REDACTED] and ultrasound examination on [REDACTED]. Thus, the patient received Eylea during the first trimester of pregnancy. On [REDACTED], the patient experienced serious diabetes mellitus (seriousness criterion: hospitalization) and on [REDACTED], the patient experienced spontaneous abortion (seriousness criterion: medically significant). The investigator did not provide a causality assessment, and no further information is available. The MH considered the events “diabetes mellitus inadequate control” and “abortion spontaneous” unrelated to Eylea, since there is no increased risk of systemic effects following IVT administration of Eylea, and pregnancy *per se* may unbalance diabetes in patients with previous diabetes.

8) Case No. [REDACTED] 28-year-old female; reported PT: “Maternal exposure during pregnancy” (verbatim: 5 weeks pregnant at the time of the injection). On an unknown date, the patient started Eylea 40 mg/mL bilaterally for treatment of DME (dose, frequency and total number of injections not reported). The patient's last menstrual period was on an unknown date; the patient received Eylea beginning at Week 5 of the pregnancy with a potential fetal exposure during the first trimester of pregnancy. No further information is currently available.

9) Case No. [REDACTED] 43-year-old female; reported PT: “Maternal exposure during pregnancy”, “stillbirth”. This 43-year-old female patient was involved in a patient support program. The patient received Eylea for diabetic retinopathy. Concurrent conditions included pericardial effusion, pleural effusion, and water retention. On an unknown date, the patient

**EYLEA®**  
(Aflibercept)  
EU Risk Management Plan

**Part II – Module SVII: Identified and Potential Risks**

---

started diuretics at an unspecified dose and frequency. From [REDACTED], the patient received Eylea. On [REDACTED], 1 day after starting and 1 day after the last dose of Eylea, the patient experienced malaise. On [REDACTED], the patient experienced respiratory disorder. On an unknown date, the patient experienced cardiac failure, renal disorder, abnormal weight loss, and abnormal weight gain. On [REDACTED], the patient experienced stillbirth. Last menstrual period and estimated date of delivery were not provided; according to the patient she had not been pregnant before. Eylea treatment was not changed.

10) Case No. [REDACTED] 32-year-old female; reported PT: “Maternal exposure during pregnancy”. This prospective pregnancy case was reported by an ophthalmologist and described drug exposure during pregnancy in a female patient (gravida 1, para 0), who received Eylea solution for injection for myopic CNV. The patient had no previous pregnancies. In MAY 2017, the patient experienced maternal exposure during pregnancy. On an unknown date, the patient started Eylea 2 mg at an unspecified frequency. A further treatment at the same dose was on [REDACTED]. Last menstrual period and estimated date of delivery were not provided. The patient received Eylea beginning at week 1 of the pregnancy with a potential fetal exposure during the first trimester of pregnancy. The reporter commented: The calculated date of conception was [REDACTED], one day prior to the Eylea injection on [REDACTED]. At the time of the initial report the patient was in the 7th week of pregnancy with no findings. No further information is currently available.

11) Case No. [REDACTED]: Female of unknown age, reported PT: “Maternal exposure during pregnancy”. This female (gravida 1) patient was involved in a company-sponsored observational study to assess the effectiveness of Eylea in routine clinical practice in patients with visual impairment due to DME (protocol No. 18058; patient ID: [REDACTED]). The patient's concurrent conditions included chronic fatigue syndrome since [REDACTED], hypertension since [REDACTED], and depression since [REDACTED]. Concomitant products included bisoprolol on [REDACTED], ramipril on [REDACTED] and venlafaxine on [REDACTED], the patient started Eylea 2 mg at an unspecified frequency. Further treatments were administered at the same dose on [REDACTED], [REDACTED]. On an unknown date, the patient experienced maternal exposure during pregnancy. The patient's last menstrual period was on [REDACTED], and estimated date of delivery is [REDACTED]. Pregnancy was verified by HCG test on [REDACTED]. The patient had received Eylea during the first trimester of pregnancy.

12) Case No. [REDACTED]: Female of unknown age, reported PT: “Maternal exposure during pregnancy”. This prospective pregnancy case was reported by a physician and describes the occurrence of exposure during pregnancy in an adult female patient who received Eylea for treatment of DME. On an unknown date, the patient started Eylea at an unspecified dose and frequency. On an unknown date, the patient experienced exposure during pregnancy. Last menstrual period and estimated date of delivery were not provided. No further information is currently available.

### **Conclusion**

Overall, these few pregnancy cases currently reported both in clinical studies and in post-marketing use do not give any rise to assume that treatment with Eylea might be associated with relevant embryo-fetotoxic effects.

**EYLEA<sup>®</sup>**

EU Risk Management Plan

**Part II – Module SVII: Identified and Potential Risks**

---

**Seriousness/outcomes**

See individual case reports described above.

**Severity and nature of risk**

See individual case reports described above.

**Background incidence/prevalence**

See individual case reports described above.

**Impact on individual patient**

Based on currently available non-clinical data, no individual impact in terms of risk to the treated population is apparent.

**Risk factor and risk groups**

Patients at risk are women of childbearing potential.

**Preventability**

Treatment with Eylea is not recommended during pregnancy, unless the potential benefit outweighs the potential risk to the fetus.

**Impact on risk-benefit balance of the product**

An educational program is performed as an additional risk minimization measure to raise patients' and physicians' awareness on identified and potential risks. The effectiveness of this program was verified with a post authorization safety study (SN 16526).

This important potential risk does not have an impact on the positive risk-benefit balance of Eylea.

**Public health impact**

Based on currently available non-clinical data, no public health impact in terms of risk to the treated population is apparent.

**PART II**

**Module SVIII: Summary of the Safety Concerns**

The safety concerns (important identified risks, important potential risks, missing information) as identified in previous Modules SII, SIV, SVI, and SVII of Part II are summarized in the following [Table SVIII.1](#). Pharmacovigilance actions associated with these safety concerns are provided in Part III (Pharmacovigilance plan).

**Table SVIII.1: Summary of safety concerns**

<b>Important identified risks</b>	<ul style="list-style-type: none"> <li>• Endophthalmitis (likely infectious origin)</li> <li>• Intraocular inflammation</li> <li>• Transient intraocular pressure increase</li> <li>• Retinal pigment epithelial tears</li> <li>• Cataract (especially of traumatic origin)</li> </ul>
<b>Important potential risks</b>	<ul style="list-style-type: none"> <li>• Medication errors</li> <li>• Off-label use and misuse</li> <li>• Embryo-fetotoxicity</li> </ul>
<b>Missing information</b>	<ul style="list-style-type: none"> <li>• Not applicable</li> </ul>

See [Part III](#) for planned actions.

 EU Risk Management Plan  
**Part III – Pharmacovigilance Plan**

## **PART III**

### **Pharmacovigilance Plan**

#### **III.1 Routine Pharmacovigilance Activities**

##### **III.1.1 Specific Adverse Reaction Follow-up Questionnaires for safety concerns**

In order to optimize the data collection for defined medical conditions, specific follow-up questionnaires will be used for endophthalmitis/intraocular inflammation and IOP increases with the PFS (see [Annex 4](#)). These specific questionnaires will be used to follow-up on any post-marketing or study reports causing suspicion of these events in order to standardize and increase the completeness of reports.

**Table Part III.1: Routine PV activities / questionnaires**

<b>Important identified risk</b>		
<b>Routine PV activities beyond adverse reactions reporting and signal detection</b>	<b>Objectives</b>	<b>Important identified risk</b>
Specific questionnaire to be used for any post-marketing or study reports suspicious for endophthalmitis and intraocular inflammation (see <a href="#">Annex 4.1</a> ).	Specific questionnaire to obtain comprehensive and standardized follow-up information about cases suspicious for endophthalmitis and intraocular inflammation.	Endophthalmitis (likely infectious origin) and intraocular inflammation.
Specific questionnaire to be used for any post-marketing or study report related to IOP increase following the use of the Bayer Eylea PFS (see <a href="#">Annex 4.2</a> ).	Specific questionnaire to obtain comprehensive and standardized follow-up information related to intraocular pressure increase following the use of the Bayer Eylea pre-filled syringe.	Transient intraocular pressure increase

##### **III.1.2 Other Forms of Routine Pharmacovigilance Activities for safety concerns**

For the safety concern of transient intraocular pressure increase following intravitreal injection: Submission of an annual report summarizing post-marketing Individual Case Safety Reports related to intraocular pressure increase and the use of the Eylea pre-filled syringe (PFS) starting from one 1 year after actual CHMP opinion date (28-OCT-2021).

Milestones for submission of the first two Annual Safety Reports on IOP increase cases with the Eylea PFS are summarized below:

	<b>Data-cut off</b>	<b>Submission to EMA</b>
<b>First Annual Safety Report</b>	All cases as of 30 SEP 2022	Q4/2022

**EYLEA<sup>®</sup>**  
**(Aflibercept)**  
 EU Risk Management Plan

**Part III – Pharmacovigilance Plan**

---

<b>Second Annual Safety Report</b>	All cases as of 30 SEP 2023	Q4/2023
------------------------------------	-----------------------------	---------

Following the submission of the second Annual Safety Report, PRAC will assess the need for continuation of Annual Safety Report creation.

Next to the above, no other forms of Routine Pharmacovigilance Activities beyond adverse reaction reporting, signal detection and the ones described above will be implemented for Eylea.

### **III.2 Additional Pharmacovigilance Activities**

There are no planned or ongoing additional pharmacovigilance activities

### **III.3 Summary Table of Additional Pharmacovigilance Activities**

There are no planned or ongoing additional pharmacovigilance activities.

Eylea should not be used during pregnancy unless the potential benefit outweighs the potential risk to the unborn child. If you are pregnant or planning to become pregnant, discuss this with your doctor before treatment with Eylea.</i>"</li> </ul> <p><b>Other routine risk minimization measures beyond the Product Information:</b> Medicinal product subject to restricted medical prescription. Eylea must only be administered by a qualified physician experienced in administering intravitreal injections</p>

## V.2 Additional Risk Minimization Measures

### V.2.1 Educational program

Besides routine risk minimization activities (SmPC and patient information), additional activity, specifically an educational program, is considered to be necessary for the important identified risks of endophthalmitis (likely infectious origin), intraocular inflammation, transient intraocular pressure increase, retinal pigment epithelium tears, and cataract (especially of traumatic origin), as well as for the important potential risk of medication errors, off-label use and misuse, and embryo-fetotoxicity. Generally, the educational material covers the indications wet AMD, CRVO, BRVO, myopic CNV, and DME.

Following the assessment (EMA/H/C/002392/II/0039) of the post authorization study 16526 (Evaluation of Physician and Patient Knowledge of Safety and Safe Use Information for Aflibercept in Europe), the MAH has updated and re-distributed the educational materials

**EYLEA<sup>®</sup>**  
(Aflibercept)  
EU Risk Management Plan

**Part V – Risk Minimisation Measures**

---

according to the PRAC Type II variation assessment report received on 08 FEB 2018. The updated Educational Material for HCPs include highlighted information regarding treatment of women of child-bearing potential, information on the injection procedure with respect to unnecessary dilation of the eye, with the need for vision and intraocular pressure evaluation after the injection as well as potential for medication misuse, particularly re-use of the vial (see EU RMP [PART III Pharmacovigilance Plan](#)). A second post authorization study (study 20285) was completed to measure the effectiveness of the updated Educational Material for physicians to evaluate their knowledge of safety and safe use information for aflibercept in Europe. Upon EMA assessment of study results, no further study to measure the effectiveness of the prescriber guide was deemed necessary. The prescriber guide was requested to be simplified and shortened to be focused on major key elements regarding Eylea.

**VI.2.1.1 Objectives and rationale for the additional risk minimization activity**

To inform patients and physicians about risks in order to minimize their occurrence and consequences in routine care. Educational material also includes guidance on the IVT injection procedure to re-train physicians in order to minimize injection-related adverse reactions. The following risks are addressed in the Educational Material: endophthalmitis/intraocular inflammation, transient intraocular pressure increase, RPE tear, cataract, medication error, off label use and misuse, and embryo-fetotoxicity.

**VI.2.1.2 Target audience and planned distribution path**

The target audience are HCPs specialized in intravitreal injections of VEGF as well as patients to be treated. The key messages of the educational materials (provided in [Part VII Annex 6](#)) will be distributed as paper version and/or through a digital communication method (digital platform) to the target audience(s). The feasibility and implementation of the planned distribution path will be agreed upon with and after liaising with the national health authorities in the member states, as requested per GVP Module XVI addendum.

**VI.2.1.3 Plans to evaluate the effectiveness of the interventions and criteria for success**

Based on PRAC recommendations following assessment of the PASS study 16526 (Evaluation of Physician and Patient Knowledge of Safety and Safe Use Information for Aflibercept in Europe) a new follow-up survey for physicians with revised Educational Material was mandated (see EU RMP Part III). This second survey (study ID 20285) was conducted between October 2019 and April 2020 and study results were submitted in October 2020. Upon EMA evaluation of study results, no further Measurement of Effectiveness Study is deemed necessary. The prescriber guide was requested to be simplified and shortened to be focused on major key elements regarding Eylea.

**V.2.2 Removal of additional risk minimization activities**

Not applicable.

EU Risk Management Plan

**Part VI – Summary of Activities in the Risk Management Plan by Product**

---

## **PART VI**

### **Summary of Activities in the Risk Management Plan by Product**

This is a summary of the EU risk management plan (RMP) for Eylea. The RMP details important risks of Eylea, how these risks can be minimized, and how more information will be obtained about Eylea's risks and uncertainties (missing information).

Eylea's summary of product characteristics (SmPC) and its package leaflet give essential information to healthcare professionals and patients on how Eylea should be used.

This summary of the RMP for Eylea should be read in the context of all this information including the assessment report of the evaluation and its plain-language summary, all which is part of the European Public Assessment Report (EPAR).

Important new concerns or changes to the current ones will be included in updates of Eylea's RMP.

#### **I The Medicine and what it is used for**

Eylea is indicated for adults for the treatment of neovascular (wet) age-related macular degeneration (AMD), visual impairment due to macular edema secondary to retinal vein occlusion (branch RVO or central RVO), visual impairment due to diabetic macular edema (DME), and visual impairment due to myopic choroidal neovascularization (myopic CNV; see SmPC for the full indication). It contains aflibercept as the active substance and it is given by intravitreal injection. The following pharmaceutical forms are currently available:

- Solution for injection in a vial. One vial contains 4 mg aflibercept in 100 microliters (40 mg/mL) in iso-osmotic solution. Delivers a single dose of 2 mg/0.05 mL.
- Solution for injection in a pre-filled syringe. One pre-filled syringe contains 3.6 mg aflibercept in 90 microliters in iso-osmotic solution. Delivers a single dose of 2 mg/0.05mL.

Further information about the evaluation of Eylea's benefits can be found in Eylea's EPAR, including in its plain-language summary, available on the EMA website, under the medicine's webpage (<https://www.ema.europa.eu/en/medicines/human/EPAR/eylea>).

#### **II Risks Associated with the Medicine and Activities to Minimize or further Characterize the Risks**

Important risks of Eylea, together with measures to minimize such risks and the proposed studies for learning more about Eylea's risks, are outlined below.

Measures to minimize the risks identified for medicinal products can be:

- Specific information, such as warnings, precautions, and advice on correct use, in the package leaflet and SmPC addressed to patients and healthcare professionals;
- Important advice on the medicine's packaging;
- The authorized pack size — the amount of medicine in a pack is chosen so to ensure that the medicine is used correctly;

**EYLEA®**  
(Aflibercept)  
EU Risk Management Plan

**Part VI – Summary of Activities in the Risk Management Plan by Product**

- The medicine's legal status — the way a medicine is supplied to the patient (e.g., with or without prescription) can help to minimize its risks.

Together, these measures constitute *routine risk minimization* measures.

In the case of Eylea, these measures are supplemented with *additional risk minimization measures* mentioned under relevant important risks, below.

In addition to these measures, information about adverse reactions is collected continuously and regularly analyzed, including PSUR assessment so that immediate action can be taken as necessary. These measures constitute *routine pharmacovigilance activities*.

If important information that may affect the safe use of Eylea is not yet available, it is listed under 'missing information' below.

## II.A List of Important Risks and Missing Information

Important risks of Eylea are risks that need special risk management activities to further investigate or minimize the risk, so that the medicinal product can be safely administered. Important risks can be regarded as identified or potential. Identified risks are concerns for which there is sufficient proof of a link with the use of Eylea. Potential risks are concerns for which an association with the use of this medicine is possible based on available data, but this association has not been established yet and needs further evaluation.

**Table Part VI.1: Summary of safety concerns**

<b>Important identified risks</b>	<ul style="list-style-type: none"> <li>• Endophthalmitis (likely infectious origin)</li> <li>• Intraocular inflammation</li> <li>• Transient intraocular pressure increase</li> <li>• Retinal pigment epithelial tears</li> <li>• Cataract (especially of traumatic origin)</li> </ul>
<b>Important potential risks</b>	<ul style="list-style-type: none"> <li>• Medication errors</li> <li>• Off-label use and misuse</li> <li>• Embryo-fetotoxicity</li> </ul>
<b>Missing information</b>	<ul style="list-style-type: none"> <li>• Not applicable</li> </ul>

## II.B Summary of Important Risks

<b>Important identified risk: Endophthalmitis (likely infectious origin)</b>	
Evidence for linking the risk to the medicine	Data from clinical trials, post-marketing surveillance and literature. The intravitreal injection procedure can implant pathogens into the eye if there is a break in sterile technique. Source of pathogenic agents is in most cases the patient's conjunctival bacterial flora.
Risk factors and risk groups	Improper aseptic technique increases the risk of intraocular inflammation.
Risk minimization	Routine risk minimization measures:

<b>Important identified risk: Endophthalmitis (likely infectious origin)</b>	
measures	<p>SmPC sections 4.2, 4.3, 4.4, and 4.8</p> <p>Package Leaflet sections 2, 3 and 4</p> <p>Other routine risk minimization measures beyond the Product Information:</p> <p>Medicinal product subject to restricted medical prescription. Eylea must only be administered by a qualified physician experienced in administering intravitreal injections</p> <p>Additional risk minimization measures:</p> <p>Educational program: Beyond routine minimization activities, additional measures are currently needed to raise patients’ and physicians’ awareness on identified and potential risks (prescriber guide and video, patient guide “Your guide to Eylea”, and its audio version).</p>

**EYLEA<sup>®</sup>**  
(Aflibercept)  
EU Risk Management Plan

**Part VI – Summary of Activities in the Risk Management Plan by Product**

<b>Important identified risk: Intraocular inflammation</b>	
Evidence for linking the risk to the medicine	Data from clinical trials, post-marketing surveillance and literature. Post-injection, sterile intraocular inflammation is a known risk following intravitreal injections of anti-VEGFs and for other intravitreally applied drugs.
Risk factors and risk groups	Improper aseptic technique increases the risk of intraocular inflammation.
Risk minimization measures	Routine risk minimization measures: SmPC sections 4.2, 4.3, 4.4, and 4.8 Package Leaflet section 2, 3 and 4 Other routine risk minimization measures beyond the Product Information: Medicinal product subject to restricted medical prescription. Eylea must only be administered by a qualified physician experienced in administering intravitreal injections  Additional risk minimization measures: Educational program: Beyond routine minimization activities, additional measures are currently needed to raise patients' and physicians' awareness on identified and potential risks (prescriber guide and video, patient guide "Your guide to Eylea", and its audio version).

<b>Important identified risk: Transient intraocular pressure increase</b>	
Evidence for linking the risk to the medicine	Data from clinical trials, post-marketing surveillance and literature. Transient IOP increase is attributed to an increase in vitreous volume after Eylea injection (volume effect).
Risk factors and risk groups	Patients with glaucoma. Increased intraocular pressure is a known adverse drug reaction on treatment with intravitreal corticosteroids.
Risk minimization measures	Routine risk minimization measures: SmPC sections 4.2, 4.4, 4.8, and 4.9 Package Leaflet sections 2 and 4 Other routine risk minimization measures beyond the Product Information: Medicinal product subject to restricted medical prescription.

**EYLEA®**

**Part VI – Summary of Activities in the Risk Management Plan by Product**

<b>Important identified risk: Transient intraocular pressure increase</b>	
	<p>Eylea must only be administered by a qualified physician experienced in administering intravitreal injections</p> <p>Additional risk minimization measures: Educational program: Beyond routine minimization activities, additional measures are currently needed to raise patients' and physicians' awareness on identified and potential risks (prescriber guide and video, patient guide "Your guide to Eylea", and its audio version).</p>

<b>Important identified risk: Retinal pigment epithelial tears</b>	
Evidence for linking the risk to the medicine	<p>Data from clinical trials, post-marketing surveillance and literature.</p> <p>Development of RPE tears after anti-VEGF intravitreal injection has been attributed to a decline in intercellular adherence, thereby increasing susceptibility to tearing of the RPE layer particularly in patients with wet AMD.</p>
Risk factors and risk groups	Wet AMD with pigment epithelial detachment; treatment of neovascularization.
Risk minimization measures	<p>Routine risk minimization measures: SmPC sections 4.4 and 4.8 Package Leaflet sections 2 and 4</p> <p>Other routine risk minimization measures beyond the Product Information: Medicinal product subject to restricted medical prescription. Eylea must only be administered by a qualified physician experienced in administering intravitreal injections</p> <p>Additional risk minimization measures: Educational program: Beyond routine minimization activities, additional measures are currently needed to raise patients' and physicians' awareness on identified and potential risks (prescriber guide and video, patient guide "Your guide to Eylea", and its audio version).</p>

**EYLEA<sup>®</sup>**  
**(Aflibercept)**  
 EU Risk Management Plan

**Part VI – Summary of Activities in the Risk Management Plan by Product**

<b>Important identified risk: Cataract (especially of traumatic origin)</b>	
Evidence for linking the risk to the medicine	Data from clinical trials, post-marketing surveillance and literature. Related to IVT procedure.
Risk factors and risk groups	Cataract is a known adverse drug reaction on treatment with IVT corticosteroids.
Risk minimization measures	<p>Routine risk minimization measures:            SmPC sections 4.2, 4.4 and 4.8            Package Leaflet sections 2, 3 and 4</p> <p>Other routine risk minimization measures beyond the Product Information:            Medicinal product subject to restricted medical prescription.            Eylea must only be administered by a qualified physician experienced in administering intravitreal injections</p> <p>Additional risk minimization measures:            Educational program: Beyond routine minimization activities, additional measures are currently needed to raise patients' and physicians' awareness on identified and potential risks (prescriber guide and video, patient guide "Your guide to Eylea", and its audio version ).</p>

**EYLEA®**  
(Aflibercept)  
EU Risk Management Plan

**Part VI – Summary of Activities in the Risk Management Plan by Product**

<b>Important potential risk: Medication errors</b>	
Evidence for linking the risk to the medicine	Although Eylea is provided in a pre-filled syringe, there is an excess volume which exceeds the recommended net dose of 2 mg Eylea per injection. Thus, injecting the entire volume of the pre-filled syringe would result in overdose. However, this numerical overdose is limited, and the drug will be administered only by qualified physicians (not by patients), and this reduces the risk of inappropriate dosing and administration as well. No clinically meaningful events of overdose have been reported so far (neither in clinical trials nor in usual care). Nevertheless, it was decided to consider "medication error" a potential risk of treatment, which is, however, completely avoidable by proper adherence to the dosing recommendations.
Risk factors and risk groups	Not applicable
Risk minimization measures	<p>Routine risk minimization measures: SmPC sections 4.2, 4.9 and 6.6 Package Leaflet section 1 and 3</p> <p>Other routine risk minimization measures beyond the Product Information: Medicinal product subject to restricted medical prescription. Eylea must only be administered by a qualified physician experienced in administering intravitreal injections</p> <p>Additional risk minimization measures: Educational program: Beyond routine minimization activities, additional measures are currently needed to raise physicians' awareness on medication error (prescriber guide and video, patient guide "Your guide to Eylea", and its audio version.</p>

**EYLEA®**  
(Aflibercept)  
EU Risk Management Plan

**Part VI – Summary of Activities in the Risk Management Plan by Product**

<b>Important potential risk: Off-label use and misuse</b>	
Evidence for linking the risk to the medicine	As with other drugs, Eylea might be intentionally used other than recommended, or in clinical conditions outside the approved indications (so-called off-label use). Since the clinical experience with Eylea in such off-label use will be limited (in particular in terms of efficacy and safety), any case of off-label use will be considered a potential risk. Since Eylea has no dependence potential, the risk of misuse is regarded as very low.
Risk factors and risk groups	Not applicable
Risk minimization measures	<p>Routine risk minimization measures: SmPC section 4.1, 4.3, 4.4 and 4.6 Package Leaflet sections 1, 2 and 3</p> <p>Other routine risk minimization measures beyond the Product Information: Medicinal product subject to restricted medical prescription. Eylea must only be administered by a qualified physician experienced in administering intravitreal injections</p> <p>Additional risk minimization measures: Educational program: Beyond routine minimization activities, additional measures are currently needed to raise patients' and physicians' awareness on off-label use (prescriber guide and video, patient guide “Your guide to Eylea”, and its audio version).</p>

**EYLEA®**  
(Aflibercept)  
EU Risk Management Plan

**Part VI – Summary of Activities in the Risk Management Plan by Product**

<b>Important potential risk: Embryo-fetotoxicity</b>	
Evidence for linking the risk to the medicine	<p>Data from clinical trials, post-marketing surveillance and literature.</p> <p>An embryo-fetal toxicity study was performed in the rabbit with IV dosing of aflibercept at doses which provided systemic exposures over 670-fold higher than that observed with IVT dosing using the clinical dose of 2 mg. The study identified dose-related increases in fetal resorptions, pregnancy disruptions and numerous fetal (external, visceral and skeletal) malformations. These effects were thought to be due to the antiangiogenic effect of aflibercept.</p>
Risk factors and risk groups	Patients at risk are women of childbearing potential.
Risk minimization measures	<p>Routine risk minimization measures: SmPC sections 4.4, 4.6 and 5.3 Package Leaflet section 2</p> <p>Other routine risk minimization measures beyond the Product Information: Medicinal product subject to restricted medical prescription. Eylea must only be administered by a qualified physician experienced in administering intravitreal injections</p> <p>Additional risk minimization measures: Educational program: Beyond routine minimization activities, additional measures are currently needed to raise patients' and physicians' awareness on the potential risk of embryo-toxicity and to underline information on treatment of women of childbearing potential, and the need for appropriate contraception in women of childbearing potential (prescriber guide and video, patient guide “Your guide to Eylea”, and its audio version).</p>

The following material is provided in this annex:

**Eylea (Aflibercept) EU Educational Material – KEY MESSAGES**

The MAH has agreed to provide EU Educational Material for Eylea. Prior to launch and during the product's lifecycle in each Member State the Marketing Authorisation Holder (MAH) will agree the final Educational Material with the National Competent Authority. The MAH ensures that, following discussions and agreement with the National Competent Authorities in each Member State where Eylea is marketed, ophthalmological clinics where Eylea is expected to be used are provided with an updated physician information pack containing the following elements:

- Physician information
- Intravitreal injection procedure video
- Intravitreal injection procedure pictogram
- Patient information packs

The physician information in the educational material contains the following key elements:

- Who should be treated with Eylea
- Sterile techniques, including periocular and ocular disinfection to minimise the risk of infection
- Use of povidone iodine or equivalent
- Techniques for the intravitreal injection
- Confirmation that the pre-filled syringe and the vial are for single use only
- The need to expel excess volume of the syringe before injecting Eylea to avoid overdose
- Patient monitoring after intravitreal injection including monitoring for visual acuity and increase of intraocular pressure post-injection
- Key signs and symptoms of intravitreal injection related adverse events including endophthalmitis, intraocular inflammation, increased intraocular pressure, retinal pigment epithelial tear and cataract
- Management of intravitreal injection related adverse events
- Female patients of childbearing potential have to use effective contraception and pregnant women should not use Eylea

The patient information pack of the educational material includes a patient information guide and its audio version. The patient information guide contains following key elements:

- Patient information leaflet
- Who should be treated with Eylea
- How to prepare for Eylea treatment
- What are the steps following treatment with Eylea

**EYLEA<sup>®</sup>**  
(Aflibercept)  
EU Risk Management Plan

**Annex 6 – Details of proposed additional risk minimisation activities**

---

- Key signs and symptoms of serious adverse events including endophthalmitis, intraocular inflammation, intraocular pressure increased, retinal pigment epithelial tear and cataract
- When to seek urgent attention from their health care provider
- Female patients of childbearing potential have to use effective contraception and pregnant women should not use Eylea

EU Risk Management Plan

**Annex 8 – Summary of Changes to the Risk Management Plan Over Time**

**Annex 8 – Summary of Changes to the Risk Management Plan Over Time**

The following changes were made to the risk management plan over time (in reverse order):

**Annex 8 Table 1: Major Changes to the Risk Management Plan over time**

Version	Date	Safety Concerns / Changes	Comment
31.2	JAN 2022	Posology utilized in marketed use was deleted as Missing information. Deletion of AZURE changes	
31.1	OCT 2021	Deletion of AZURE study details	This version was not EMA approved and led to further amendments (see Version 31.2).
30.3	OCT 2021	Based on PRAC request removal of following topics of Missing Information due to absence of additional PV activities: -Missing information Use of Eylea® in patients with uncontrolled glaucoma, -Concomitant use of different anti-VEGF therapies and other therapies for wet AMD, CRVO and DME (including bilateral treatment with anti- VEGFs.), -Long term safety beyond 2 years -Use of Eylea in breastfeeding women.  Annex 6: removal of information on Eylea use and breastfeeding from Key Messages of Educational Material (based on PRAC request)	
30.2	SEP 2021	- Updated to remove identified and potential risks not associated with additional risk minimisation measures: retinal tear/detachment, hypersensitivity and immunology, arterial thromboembolic events, venous thromboembolic events, hypertension and non-ocular hemorrhage - Updated to include missing information topic “Use of Eylea in breastfeeding women” -Key Messages/Annex 6 updated to remove SmPC from Educational material Package for HCPs. Further, renaming audio-CD for patients to “audio version” to allow further audio modalities other than CD	This version was not EMA approved and led to further amendments (see Version 30.3)
30.1	MAY 2021	• Milestones added for two Annual Safety Reports on IOP increases with PFS	This version was not EMA approved and led to further amendments

**EYLEA<sup>®</sup>**

31.2	JAN 2022	Posology utilized in marketed use was deleted as Missing information. Deletion of AZURE changes	
31.1	OCT 2021	Deletion of AZURE study details	This version was not EMA approved and led to further amendments (see Version 31.2).
		<ul style="list-style-type: none"> <li>• Updates of section on Measurement of Effectiveness of additional Risk Minimization Activities to indicate that no further PASS to evaluate the effectiveness of Educational Material is necessary and the Prescriber Guide will be revised to simplify and shorten to be focused on major key elements regarding Eylea.</li> <li>• Added to Annex 4: Targeted Follow-Up Questionnaire for IOP increases with PFS</li> <li>• Annex 6: Key messages adapted to delete: “Use of antibiotics according to national guidelines” from Prescriber Guide</li> </ul>	(Version 30.2)
29.2	09 MAR 2021	For the safety concern of transient intraocular pressure increase following intravitreal injection a Specific Adverse Reaction Follow-up Questionnaire was added to collect information on intraocular pressure increase cases after the use of Bayer’s Eylea pre-filled syringe.  For the safety concern of transient intraocular pressure increase following intravitreal injection, another form of routine pharmacovigilance activity was added: Submission of an annual report summarizing post-marketing Individual Case Safety Reports related to intraocular pressure increase and the use of the Eylea pre-filled syringe (PFS) starting from 1 year after the update of the Educational Material and for at least two years. Timelines will be defined within the Type II variation.	Questionnaire will be added to Annex 4 after EMA review
29.1	24 FEB 2021	<ul style="list-style-type: none"> <li>• Table of content added</li> <li>• Index of tables added</li> </ul>
